### ABSTRACT

---

The notion of sum  $\delta$ -connected proximity spaces which contain the category of  $\delta$ -connected and locally  $\delta$ -connected spaces is defined. Several characterizations of it are substantiated. Weaker forms of sum  $\delta$ -connectedness are also studied.

---

2010 MSC: 54E05; 54D05.

KEYWORDS: sum  $\delta$ -connected;  $\delta$ -connected;  $\delta$ -component; locally  $\delta$ -connected.

### 1. INTRODUCTION

The notion of proximity was introduced by Efremovic [4, 5] as a natural generalization of metric spaces and topological groups. Smirnov [10, 11] and Naimpally [8, 9] did the most significant and extensive work in this area. In 2009, Bezhnashvili [1] defined zero-dimensional proximities and zero-dimensional compactifications.

Mrówka *et al.* [7] introduced the theory of  $\delta$ -connectedness (or equiconnect- edness) in proximity spaces. Consequently, Dimitrijević *et al.* [2, 3] defined local  $\delta$ -connectedness,  $\delta$ -component and the treelike proximity spaces. In 1978, Kohli [6] introduced the notion of sum connectedness in topological spaces.

We discuss sum  $\delta$ -connectedness in proximity spaces in this paper. Some necessary definitions and the results which are used in further sections, are recalled in Section 2. In Section 3, sum  $\delta$ -connectedness is defined and its relations with other kinds of connectedness are determined. Several characterizations of

it are established. It is shown that sum  $\delta$ -connectedness is equivalent to local  $\delta$ -connectedness in a zero-dimensional proximity space. Further, the Stone-Ćech compactification of a separated proximity space  $X$  is sum  $\delta$ -connected if and only if  $X$  is sum  $\delta$ -connected and it has finitely many  $\delta$ -components. For a sum  $\delta$ -connected proximity space to be sum connected, a sufficient condition is deduced. In the last section, weaker forms of sum  $\delta$ -connectedness are defined. Finally, if a sum  $\delta$ -connected space is  $\delta$ -padded, then it is also locally  $\delta$ -connected.

## 2. PRELIMINARIES

**Definition 2.1** ([9]). A binary relation  $\delta$  on the power set  $\mathcal{P}(X)$  of  $X$  is said to be a proximity on  $X$ , if the following axioms are satisfied for all  $P, Q, R$  in  $\mathcal{P}(X)$ :

- (i)  $(\phi, P) \notin \delta$ ;
- (ii) If  $P \cap Q \neq \phi$ , then  $(P, Q) \in \delta$ ;
- (iii) If  $(P, Q) \in \delta$ , then  $(Q, P) \in \delta$ ;
- (iv)  $(P, Q \cup R) \in \delta$  if and only if  $(P, Q) \in \delta$  or  $(P, R) \in \delta$ ;
- (v) If  $(P, Q) \notin \delta$ , then there exists a subset  $R$  of  $X$  such that  $(P, R) \notin \delta$  and  $(X \setminus R, Q) \notin \delta$ .

The pair  $(X, \delta)$  is called a proximity space.

Throughout this paper, we simply write proximity space  $(X, \delta)$  as  $X$  whenever there is no confusion of the proximity  $\delta$ .

**Definition 2.2** ([8, 9]). A proximity space  $X$  is said to be separated if  $x = y$  whenever  $(\{x\}, \{y\}) \in \delta$  for  $x, y \in X$ .

**Proposition 2.3** ([9]). Let  $X$  be a proximity space and  $P$  be a subset of  $X$ . If  $P$  is  $\delta$ -closed if and only if  $x \in P$  whenever  $(\{x\}, P) \in \delta$ , then the collection of the complements of all  $\delta$ -closed sets forms a topology  $\mathcal{T}_\delta$  on  $X$ .

**Proposition 2.4** ([9]). Let  $X$  be a proximity space. Then the closure  $C(P)$  of  $P$  with respect to  $\mathcal{T}_\delta$  is given by  $C(P) = \{x \in X : (\{x\}, P) \in \delta\}$ .

**Corollary 2.5** ([9]). Let  $X$  be a proximity space. Then  $M \in \mathcal{T}_\delta$  if and only if  $(\{x\}, X \setminus M) \notin \delta$  for every  $x \in M$ .

Using Proposition 2.4, a set  $F$  is  $\delta$ -closed if  $C(F) = F$ . From Corollary 2.5, a set  $U$  is  $\delta$ -open, if  $(\{x\}, X \setminus U) \notin \delta$  for every  $x \in U$ .

**Definition 2.6** ([9]). Let  $X$  be a proximity space and  $\mathcal{T}$  be a topology on  $X$ . Then  $\delta$  is said to be compatible with  $\mathcal{T}$  if the generated topology  $\mathcal{T}_\delta$  and  $\mathcal{T}$  are equal, that is,  $\mathcal{T}_\delta = \mathcal{T}$ .

**Definition 2.7** ([9]). Let  $X$  be a proximity space. Then a subset  $N$  of  $X$  is said to be a  $\delta$ -neighbourhood of  $M \subset X$  if  $(M, X \setminus N) \notin \delta$ . It is denoted by  $M \ll_\delta N$ .

**Definition 2.8** ([9]). Let  $(X, \delta)$  and  $(Y, \delta')$  be two proximity spaces. Then a map  $f : (X, \delta) \rightarrow (Y, \delta')$  is said to be  $\delta$ -continuous ( or  $p$ -continuous ) if  $(f(P), f(Q)) \in \delta'$  whenever  $(P, Q) \in \delta$ , for all  $P, Q \subset X$ .

**Definition 2.9** ([7]). Let  $X$  be a proximity space. Then  $X$  is said to be  $\delta$ -connected if every  $\delta$ -continuous map from  $X$  to a discrete proximity space is constant.

**Theorem 2.10** ([7]). Let  $X$  be a proximity space. Then the following statements are equivalent:

- (i)  $X$  is  $\delta$ -connected.
- (ii)  $(P, X \setminus P) \in \delta$  for each nonempty subset  $P$  with  $P \neq X$ .
- (iii) For every  $\delta$ -continuous real-valued function  $f$ , the image  $f(X)$  is dense in some interval of  $\mathbb{R}$ .
- (iv) If  $X = P \cup Q$  and  $(P, Q) \notin \delta$ , then either  $P = \emptyset$  or  $Q = \emptyset$ .

**Definition 2.11** ([2]). Let  $X$  be a proximity space and  $x \in X$ . Then the  $\delta$ -component of a point  $x$  is defined as the union of all  $\delta$ -connected subsets of  $X$  containing  $x$ . It is denoted by  $C_\delta(x)$ .

**Definition 2.12** ([2]). Let  $X$  be a proximity space and  $x \in X$ . Then the  $\delta$ -quasi component of  $x$  is the equivalence class of  $x$  with respect to the equivalence relation  $\sim$  defined on  $X$  as “  $x \sim y$  if and only if there do not exist the sets  $M, N$  such that  $x \in M$  and  $y \in N$  with  $X = M \cup N$  and  $(M, N) \notin \delta$ ”.

**Definition 2.13** ([2]). A proximity space  $X$  is called locally  $\delta$ -connected if for every point  $x$  of  $X$  and for every  $\delta$ -neighbourhood  $N$  of  $x$ , there exists some  $\delta$ -connected  $\delta$ -neighbourhood  $M$  of  $x$  such that  $x \in M \subset N$ .

**Definition 2.14** ([12]). Let  $(X, \delta)$  be a proximity space and  $f : X \rightarrow Y$  be a surjective map, where  $Y$  is any set. Then the quotient proximity on  $Y$  is the finest proximity such that the map  $f$  is  $\delta$ -continuous. When  $Y$  has the quotient proximity,  $f$  is called  $\delta$ -quotient map.

**Proposition 2.15** ([12]). Let  $(X, \delta)$  be a proximity space and  $f : X \rightarrow Y$  be a surjective map, where  $Y$  be any set. Then the quotient proximity  $\delta'$  on  $Y$  is given by  $P \ll_{\delta'} Q$  if and only if for each binary rational  $s \in [0, 1]$ , there is some  $P_s \subseteq Y$  such that  $P_0 = P$ ,  $P_1 = Q$  and  $s < t$  implies  $f^{-1}(P_s) \ll_\delta f^{-1}(P_t)$ .

**Proposition 2.16** ([12]). Let  $(X, \delta)$  be a proximity space and  $f : X \rightarrow Y$  be a surjective map such that  $f^{-1}(f(M)) = M$  for each  $\delta$ -open set  $M$  of  $X$ , where  $Y$  be any set. Then the quotient proximity  $\delta'$  on  $Y$  is given by  $(P, Q) \in \delta'$  if and only if  $(f^{-1}(P), f^{-1}(Q)) \in \delta$ .

**Definition 2.17** ([1]). A proximity space  $X$  is said to be zero-dimensional if the proximity  $\delta$  satisfies the following axiom:

If  $(P, Q) \notin \delta$ , then there is a subset  $R$  of  $X$  such that  $(R, X \setminus R) \notin \delta$ ,  $(P, R) \notin \delta$  and  $(X \setminus R, Q) \notin \delta$ .

**Definition 2.18** ([6]). A topological space  $X$  is said to be sum connected at  $x \in X$ , if there exists an open connected neighbourhood of  $x$ . If  $X$  is sum connected at each of its points, then  $X$  is called sum connected.

**Proposition 2.19** ([6]). Let  $X^*$  be the Stone-Ćech compactification of a Tychonoff space  $X$ . Then  $X$  is sum connected and has finitely many components, if  $X^*$  is sum connected.

### 3. SUM $\delta$ -CONNECTEDNESS

**Definition 3.1.** A proximity space  $X$  is said to be sum  $\delta$ -connected at  $x \in X$  if there exists a  $\delta$ -connected  $\delta$ -open  $\delta$ -neighbourhood of  $x$ . If  $X$  is sum  $\delta$ -connected at each of its points, then it is said to be sum  $\delta$ -connected.

**Definition 3.2.** Let  $(X_i, \delta_i)_{i \in \mathcal{I}}$  be a family of proximity spaces, where  $\mathcal{I}$  is an index set. A proximity space  $(X, \delta)$  is said to be a far proximity sum of  $(X_i)_{i \in \mathcal{I}}$  if  $X = \bigcup_{i \in \mathcal{I}} X_i$  and  $(X_i, X_j) \notin \delta$  for all  $i \neq j$  in  $\mathcal{I}$  with  $\delta|_{X_i} = \delta_i$  for all  $i \in \mathcal{I}$ .

Note that a proximity space  $X$  is sum  $\delta$ -connected if and only if each of its  $\delta$ -component is  $\delta$ -open. Therefore, every  $\delta$ -connected proximity space is sum  $\delta$ -connected.

**Example 3.3.**

- (i) Let  $X$  be any discrete proximity space with  $|X| \geq 2$ . Then  $X$  is sum  $\delta$ -connected but not  $\delta$ -connected.
- (ii) Let  $X = (0, 1) \cup (2, 3)$  with usual subspace proximity of  $\mathbb{R}$ . Then  $X$  is sum  $\delta$ -connected but not  $\delta$ -connected.

Every sum connected proximity space is sum  $\delta$ -connected. But, converse may not be true. However, in compact separated proximity spaces, the notion of sum connectedness and sum  $\delta$ -connectedness coincides.

**Example 3.4.** The space  $\mathbb{Q}$  of rationals with the usual proximity is sum  $\delta$ -connected. But, it is not sum connected.

Every locally  $\delta$ -connected proximity space is sum  $\delta$ -connected. Converse may not be true.

**Example 3.5.** Consider  $T = \{(x, \sin \frac{1}{x}) : 0 < x \leq 1\} \cup \{(0, y) : -1 \leq y \leq 1\}$  the closed Topologist's Sine curve with subspace proximity induced from  $\mathbb{R}^2$ . Let  $X$  be the far proximity sum of two copies of  $T$ . Then  $X$  is sum  $\delta$ -connected but it is neither  $\delta$ -connected nor locally  $\delta$ -connected.

**Example 3.6.** Let  $X = \{0\} \cup \{\frac{1}{n} : n \in \mathbb{N}\}$  be a proximity space. Since each  $\{\frac{1}{n}\}$  is  $\delta$ -clopen in  $X$ , there does not exist any  $\delta$ -connected  $\delta$ -neighbourhood of 0 in  $X$  because every  $\delta$ -neighbourhood of 0 contains infinitely many members of  $X \setminus \{0\}$ . Thus,  $X$  is not sum  $\delta$ -connected at 0.

Thus, we have following relationship among several connectednesses in proximity space.

$$\begin{array}{ccccc}
 \text{connected} & \implies & \text{sum connected} & \iff & \text{locally connected} \\
 \Downarrow & & \Downarrow & & \Downarrow \\
 \delta\text{-connected} & \implies & \text{sum } \delta\text{-connected} & \iff & \text{locally } \delta\text{-connected}
 \end{array}$$

The following theorem gives some necessary and sufficient conditions for sum  $\delta$ -connectedness.

**Theorem 3.7.** *For a proximity space  $X$ , the following statements are equivalent:*

- (i)  $X$  is sum  $\delta$ -connected.
- (ii) For each  $x \in X$  and each  $\delta$ -clopen set  $U$  which contains  $x$ , there exists a  $\delta$ -open  $\delta$ -connected set  $W$  containing  $x$  such that  $W \subset U$ .
- (iii)  $\delta$ -components of  $\delta$ -clopen sets in  $X$  are  $\delta$ -open in  $X$ .

*Proof.* (i)  $\implies$  (ii). Let  $x \in X$  and  $U$  be a  $\delta$ -clopen set such that  $x \in U$ . Let  $C_\delta(x)$  be the  $\delta$ -component of  $X$  containing  $x$ . By hypothesis,  $C_\delta(x)$  is  $\delta$ -open. So,  $C_\delta(x) \cap U$  is  $\delta$ -clopen. Therefore,  $((C_\delta(x) \cap U), C_\delta(x) \setminus (C_\delta(x) \cap U)) \notin \delta$  as  $C_\delta(x) \cap U \subset C_\delta(x) \subset X$ . Also, since  $C_\delta(x)$  is  $\delta$ -connected,  $C_\delta(x) \cap U = C_\delta(x)$ . Hence,  $C_\delta(x)$  is a  $\delta$ -open  $\delta$ -connected such that  $C_\delta(x) \subset U$ .

(ii)  $\implies$  (iii). Let  $U$  be any  $\delta$ -clopen set in  $X$  and  $C_\delta$  be a  $\delta$ -component of  $U$ . Then, by hypothesis, for each  $x \in C_\delta$  there exists a  $\delta$ -open  $\delta$ -connected set  $W$  such that  $x \in W \subset U$ . Therefore,  $W \subset C_\delta$  as  $C_\delta$  is  $\delta$ -component. Hence,  $C_\delta$  is  $\delta$ -open.

(iii)  $\implies$  (i). Since  $X$  is  $\delta$ -clopen, the result follows. □

**Proposition 3.8.** *Let  $Y$  be a dense proximity subspace of  $X$  and  $x \in Y$ . Then  $X$  is sum  $\delta$ -connected at  $x$  if  $Y$  is sum  $\delta$ -connected at  $x$ .*

*Proof.* Let  $W$  be a  $\delta$ -open  $\delta$ -connected  $\delta$ -neighbourhood of  $x$  in  $Y$ . Therefore,  $W = U \cap Y$ , where  $U$  is  $\delta$ -open  $\delta$ -neighbourhood of  $x$  in  $X$ . Thus,  $W \subset U$  and  $U \subset Cl_X(U) = Cl_X(W)$  as  $Y$  is dense in  $X$ . Note that  $Cl_X(W)$  is  $\delta$ -connected. Hence,  $U$  is  $\delta$ -open  $\delta$ -connected  $\delta$ -neighbourhood of  $x$  in  $X$ . □

Next example shows that the closure of sum  $\delta$ -connected proximity space may not be sum  $\delta$ -connected.

**Example 3.9.** Let  $X = \{\frac{1}{n} : n \in \mathbb{N}\}$  be a proximity subspace of  $\mathbb{R}$ . Then each  $\delta$ -component  $\{\frac{1}{n}\}$  is  $\delta$ -clopen in  $X$ . So,  $X$  is sum  $\delta$ -connected. But, note that  $Cl(X) = \{0\} \cup \{\frac{1}{n} : n \in \mathbb{N}\}$  is not sum  $\delta$ -connected at 0 by Example 3.6.

**Proposition 3.10.** *Let  $X$  be a sum  $\delta$ -connected proximity space and  $f : (X, \delta) \rightarrow (Y, \delta^*)$  be a  $\delta$ -quotient map such that  $f^{-1}(f(U)) = U$  for each  $\delta$ -open subset  $U$  of  $X$ . Then  $Y$  is sum  $\delta$ -connected.*

*Proof.* Let  $C_\delta$  be any  $\delta$ -component of  $Y$  and  $y \in C_\delta$ . We have to show that  $(y, Y \setminus C_\delta) \notin \delta^*$ . By definition of  $\delta$ -quotient proximity  $\delta^*$ , it suffices to show that  $(f^{-1}(y), X \setminus f^{-1}(C_\delta)) \notin \delta$ . Let  $x \in f^{-1}(y)$ , then the  $\delta$ -component  $C_x$  of  $x$  in  $X$ , be  $\delta$ -open in  $X$ . Therefore,  $(z, X \setminus C_x) \notin \delta$  for every  $z \in C_x$ . Since

$f$  is  $\delta$ -continuous,  $f(C_x)$  is  $\delta$ -connected. Thus,  $y = f(x) \in f(C_x) \cap C_\delta$ . So  $f(C_x) \subseteq C_\delta$ , which implies  $C_x \subseteq f^{-1}(C_\delta)$ . Then,  $(z, X \setminus f^{-1}(C_\delta)) \notin \delta$  for every  $z \in C_x$ . In particular,  $(f^{-1}(y), X \setminus f^{-1}(C_\delta)) \notin \delta$ .  $\square$

**Corollary 3.11.** *Let  $f : (X, \delta) \longrightarrow (Y, \delta^*)$  be a  $\delta$ -continuous,  $\delta$ -closed, surjection such that  $f^{-1}(f(U)) = U$  for each  $\delta$ -open subset  $U$  of  $X$ . If  $X$  is sum  $\delta$ -connected, then  $Y$  is also sum  $\delta$ -connected.*

**Proposition 3.12.** *Every  $\delta$ -continuous,  $\delta$ -open image of a sum  $\delta$ -connected proximity space is sum  $\delta$ -connected.*

*Proof.* Let  $f : (X, \delta) \longrightarrow (Y, \delta')$  be a  $\delta$ -continuous,  $\delta$ -open, surjective map and  $X$  be sum  $\delta$ -connected. Let  $C_\delta$  be a  $\delta$ -component of  $Y$  and  $x \in f^{-1}(C_\delta)$ . Then there is a  $\delta$ -component  $C_x$  in  $X$  containing  $x$  which is  $\delta$ -open. Since  $f$  is  $\delta$ -continuous and  $\delta$ -open,  $f(C_x) \subseteq C_\delta$  and  $f(C_x)$  is  $\delta$ -open. Therefore,  $(f(x), Y \setminus f(C_x)) \notin \delta'$ . Hence,  $(f(x), Y \setminus C_\delta) \notin \delta'$ .  $\square$

**Corollary 3.13.** *If the product of proximity spaces is sum  $\delta$ -connected, then each of its factor is also sum  $\delta$ -connected.*

The product of sum  $\delta$ -connected proximity spaces need not be sum  $\delta$ -connected in general.

**Example 3.14.** Let  $X = \{0, 1\}^\omega$  be infinite product of two point discrete proximity spaces. Then  $X$  is not discrete proximity space. Therefore, the  $\delta$ -component  $C_\delta(x)$  of  $x$  in  $X$  is  $\{x\}$  itself, which is not  $\delta$ -open. Hence,  $X$  is not sum  $\delta$ -connected.

**Theorem 3.15.** *Let  $(X, \delta)$  be a product of proximity spaces  $(X_i, \delta_i)_{i \in \mathcal{I}}$ , where  $\mathcal{I}$  is an index set. Then  $X = \prod_{i \in \mathcal{I}} X_i$  is sum  $\delta$ -connected if and only if each  $X_i$  is sum  $\delta$ -connected and all but finitely many  $X_i$ 's are  $\delta$ -connected.*

*Proof.* Let  $X$  be sum  $\delta$ -connected. So, by Corollary 3.13, each  $X_i$  is sum  $\delta$ -connected. Now, suppose that all but finitely many  $X_i$ 's are not  $\delta$ -connected. Then any  $\delta$ -component of  $X$  is not  $\delta$ -open in  $X$ , which is a contradiction.

Conversely, assume that each  $X_i$  is sum  $\delta$ -connected and all but finitely many  $X_i$ 's are  $\delta$ -connected. Let  $C_\delta$  be any  $\delta$ -component of  $X$  and  $p_i$  be the  $i^{\text{th}}$  projection map. Then  $p_i(C_\delta)$  is  $\delta$ -connected for each  $i \in \mathcal{I}$ . Therefore,  $\prod_{i \in \mathcal{I}} p_i(C_\delta)$  is also  $\delta$ -connected. Thus,  $C_\delta = \prod_{i \in \mathcal{I}} p_i(C_\delta)$ . For each  $i \in \mathcal{I}$ , suppose  $C_{\delta_i}$  be the  $\delta_i$ -component of  $X_i$  containing  $p_i(C_\delta)$ . Put  $C'_\delta = \prod_{i \in \mathcal{I}} C_{\delta_i}$ . If  $p_i(C_\delta) \subsetneq C_{\delta_i}$ , then  $C_\delta = C'_\delta$  as  $C_\delta$  is  $\delta$ -component of  $X$ . Thus,  $p_i(C_\delta) = C_{\delta_i}$  for each  $i \in \mathcal{I}$ . Since all but finitely many  $X_i$ 's are  $\delta$ -connected,  $p_i(C_\delta) = C_{\delta_i} = X_i$  for all but finitely many  $i \in \mathcal{I}$ . Hence,  $C_\delta$  is  $\delta$ -open set in  $X$ .  $\square$

**Theorem 3.16.** *Every far proximity sum of sum  $\delta$ -connected proximity spaces is sum  $\delta$ -connected.*

It can be easily shown that a  $\delta$ -closed subspace of sum  $\delta$ -connected proximity space need not be sum  $\delta$ -connected.

**Corollary 3.17.** *A proximity space  $X$  is locally  $\delta$ -connected if and only if every  $\delta$ -open subspace of  $X$  is sum  $\delta$ -connected.*

**Theorem 3.18.** *Let  $X$  be a pseudocompact, separated, sum  $\delta$ -connected proximity space. Then it has at most finitely many  $\delta$ -components.*

*Proof.* Suppose  $X$  has infinitely many  $\delta$ -components. Since collection of  $\delta$ -components of  $X$  is locally finite and each  $\delta$ -component of  $X$  is  $\delta$ -open, we have a locally finite collection of non-empty  $\delta$ -open sets which is not finite, a contradiction.  $\square$

**Corollary 3.19.** *If  $X$  is compact sum  $\delta$ -connected proximity space, then it has at most finitely many  $\delta$ -components.*

**Corollary 3.20.** *If  $X$  is Lindelof (or separable) sum  $\delta$ -connected proximity space, then it has at most countably many  $\delta$ -components.*

**Theorem 3.21.** *Every separated, zero-dimensional, sum  $\delta$ -connected proximity space is discrete.*

*Proof.* Let  $X$  be any separated, zero-dimensional, sum  $\delta$ -connected proximity space. Let  $S$  be a subset of  $X$  such that  $x, y \in S$  with  $x \neq y$ . Therefore,  $(\{x\}, \{y\}) \notin \delta$ . Then, there exists  $C \subset X$  such that  $(C, X \setminus C) \notin \delta$ ,  $(\{x\}, C) \notin \delta$  and  $(X \setminus C, \{y\}) \notin \delta$ . So,  $(C, S \setminus C) \notin \delta$  which implies  $S$  is not  $\delta$ -connected. Hence, every  $\delta$ -component of  $X$  is singleton. As  $X$  is sum  $\delta$ -connected, each singleton of  $X$  is  $\delta$ -open.  $\square$

Next theorem shows that in a zero-dimensional proximity space, local  $\delta$ -connectedness and sum  $\delta$ -connectedness are equivalent.

**Proposition 3.22.** *A zero-dimensional proximity space  $X$  is locally  $\delta$ -connected if and only if it is sum  $\delta$ -connected.*

*Proof.* Necessity is obvious. For the sufficient part, let  $X$  be sum  $\delta$ -connected. Let  $x \in X$  and  $U$  be a  $\delta$ -neighbourhood of  $x$ . Therefore, there exists  $C \subset X$  such that  $(C, X \setminus C) \notin \delta$ ,  $(\{x\}, X \setminus C) \notin \delta$  and  $(C, X \setminus U) \notin \delta$ . Thus,  $C$  is  $\delta$ -clopen and  $x \in C \subset U$ . So, by Theorem 3.7, there exists a  $\delta$ -open  $\delta$ -connected set  $W$  such that  $x \in W \subset C \subset U$ . Hence,  $X$  is locally  $\delta$ -connected.  $\square$

Now, we find the relation of sum  $\delta$ -connectedness of proximity space with its Stone-Ćech compactification.

**Theorem 3.23.** *Let  $(X^*, \delta^*)$  be the Stone-Ćech compactification of the separated proximity space  $(X, \delta)$ . Then  $X^*$  is sum  $\delta$ -connected if and only if  $X$  is sum  $\delta$ -connected and has finitely many  $\delta$ -components.*

*Proof.* Let  $X^*$  be sum  $\delta$ -connected. Then, by Corollary 3.19, it has finitely many  $\delta$ -components. So,  $X^* = \bigcup_{i=1}^n C_\delta^i$ , where  $C_\delta^i$  is a  $\delta$ -component of  $X^*$  for each  $1 \leq i \leq n$ . Therefore,  $X = \bigcup_{i=1}^n (C_\delta^i \cap X)$ . As each  $C_\delta^i \cap X$  is  $\delta$ -open in  $X$  and  $(C_\delta^i \cap X, C_\delta^j \cap X) \notin \delta$  by using hypothesis, it suffices to show that each  $C_\delta^i \cap X$  is  $\delta$ -connected. Let  $C_\delta^i \cap X = P \cup Q$  with  $(P, Q) \notin \delta^*$ . Note that

$Cl_{\delta^*}(C_\delta^i \cap X) = C_\delta^i$  because  $C_\delta^i$  is  $\delta$ -open in  $X^*$  and  $X$  is dense in  $X^*$ . Therefore,  $C_\delta^i = Cl_{\delta^*}(C_\delta^i \cap X) = Cl_{\delta^*}(P) \cup Cl_{\delta^*}(Q)$  with  $(Cl_{\delta^*}(P), Cl_{\delta^*}(Q)) \notin \delta^*$ . Thus,  $C_\delta^i$  is not  $\delta$ -connected, a contradiction.

Conversely, assume  $X$  is sum  $\delta$ -connected and has finitely many  $\delta$ -components. Therefore,  $X = \bigcup_{i=1}^n C_\delta^i$  where  $C_\delta^i$  is a  $\delta$ -component of  $X$  for each  $1 \leq i \leq n$ . Thus,  $X^* = Cl_{\delta^*}(X) = \bigcup_{i=1}^n Cl_{\delta^*}(C_\delta^i)$ . Since,  $(C_\delta^i, C_\delta^j) \notin \delta$  for  $i \neq j$ ,  $(Cl_{\delta^*}(C_\delta^i), Cl_{\delta^*}(C_\delta^j)) \notin \delta^*$ . Note that each  $Cl_{\delta^*}(C_\delta^i)$  is  $\delta$ -connected in  $X^*$ . Thus, each  $Cl_{\delta^*}(C_\delta^i)$  is a  $\delta$ -component in  $X^*$ . Since  $\delta$ -components in  $X^*$  are finite, hence  $X^*$  is sum  $\delta$ -connected.  $\square$

**Corollary 3.24.** *If  $X$  is pseudocompact, separated and sum  $\delta$ -connected proximity space, then its Stone-Ćech compactification  $X^*$  is also sum  $\delta$ -connected.*

Every sum connected proximity space is sum  $\delta$ -connected. Following theorem gives the sufficient condition for a sum  $\delta$ -connected proximity space to be sum connected.

**Theorem 3.25.** *Let  $(X, \mathcal{T})$  be a Tychonoff space. If  $X$  is sum  $\delta$ -connected and has finitely many  $\delta$ -components with respect to any proximity  $\delta$  compatible with  $\mathcal{T}$ , then  $X$  is sum connected. Moreover, it has at most finitely many components.*

*Proof.* Let  $\mathcal{S}$  be the collection of all proximities which are compatible with  $\mathcal{T}$ . Let  $\delta_0 = \sup \mathcal{S}$ , then  $\delta_0$  is also compatible with  $\mathcal{T}$ . Therefore, by hypothesis,  $X$  is sum  $\delta_0$ -connected and has finitely many  $\delta_0$ -components with respect to  $\delta_0$ . Since  $\delta_0 = \sup \mathcal{S}$ , the compactification  $(X^*, \delta^*)$  corresponding to  $\delta_0$  is Stone-Ćech compactification. So, by Theorem 3.23,  $X^*$  is sum  $\delta_0$ -connected. Thus,  $X^*$  is sum connected. By Proposition 2.19,  $X$  is sum connected and has finitely many components.  $\square$

#### 4. WEAKER FORMS OF SUM $\delta$ -CONNECTEDNESS

In this section we give proximity versions of notions defined and considered in [6].

**Definition 4.1.** Let  $X$  be a proximity space which contains a point  $x$ . Then  $X$  is called :

- (i) weakly sum  $\delta$ -connected at  $x$  if there exists a  $\delta$ -connected  $\delta$ -neighbourhood of  $x$ .
- (ii) quasi sum  $\delta$ -connected at  $x$  if the  $\delta$ -quasi component which contains  $x$  is a  $\delta$ -neighbourhood of  $x$ .
- (iii)  $\delta$ -padded at  $x$  if for every  $\delta$ -neighbourhood  $W$  of  $x$  there exist  $\delta$ -open sets  $U$  and  $V$  such that  $x \in U \subseteq Cl_\delta(U) \subseteq V \subseteq W$  and  $V \setminus Cl_\delta(U)$  has at most finitely many  $\delta$ -components.

If a proximity space  $X$  is weakly sum  $\delta$ -connected (or quasi sum  $\delta$ -connected) at each of its points, then the space  $X$  is called weakly sum  $\delta$ -connected (or quasi sum  $\delta$ -connected). For a proximity space  $X$ ,

sum  $\delta$ -connected  $\Rightarrow$  weakly sum  $\delta$ -connected  $\Rightarrow$  quasi sum  $\delta$ -connected

**Example 4.2.** In  $\mathbb{R}^2$ , let  $B_n$  be the infinite broom containing all the closed line segments joining the point  $(\frac{1}{n}, 0)$  to the points  $\{(\frac{1}{n+1}, \frac{1}{m}) : m = n, n+1, \dots\}$ , where  $n = 1, 2, \dots$ . Let  $B = \bigcup_{n=1}^{\infty} B_n$  and  $A = \{(x, 0) : 0 \leq x \leq 2\} \cup \{(y, \frac{1}{n}) : 1 \leq y \leq 2 \text{ and } n = 1, 2, \dots\}$ . Let  $X = A \cup B$ . Then note that  $X$  is compact. Therefore, connectedness is equivalent to  $\delta$ -connectedness. Hence,  $X$  is weak sum  $\delta$ -connected but not sum  $\delta$ -connected at  $(0, 0)$ .

**Lemma 4.3.** *Every  $\delta$ -open  $\delta$ -quasi component is a  $\delta$ -component.*

*Proof.* Let  $U$  be a  $\delta$ -open  $\delta$ -quasi component of proximity space  $X$  and  $x \in U$ . Let  $V$  be the  $\delta$ -component of  $x$ . Then  $V \subset U$ . Let  $y \in U \setminus V$ . So,  $x \sim y$ . Since  $V$  is  $\delta$ -closed in  $X$  and  $V \subset U$ ,  $V$  is  $\delta$ -closed in  $U$ . So,  $U \setminus V$  is  $\delta$ -open in  $U$ . As  $U$  is  $\delta$ -open in  $X$ ,  $U \setminus V$  is  $\delta$ -open in  $X$ . Therefore,  $(U \setminus V, X \setminus (U \setminus V)) \notin \delta$ . Thus,  $X = (U \setminus V) \cup (X \setminus (U \setminus V))$  with  $(U \setminus V, X \setminus (U \setminus V)) \notin \delta$ . Hence,  $x \approx y$  which is a contradiction.  $\square$

**Proposition 4.4.** *For a given proximity space  $X$ , the following statements are comparable:*

- (i)  $X$  is quasi sum  $\delta$ -connected.
- (ii)  $X$  is weakly sum  $\delta$ -connected.
- (iii)  $X$  is sum  $\delta$ -connected.
- (iv)  $\delta$ -components of  $X$  are  $\delta$ -open.
- (v)  $\delta$ -quasi components of  $X$  are  $\delta$ -open.

*Proof.* By Lemma 4.3,  $\delta$ -open  $\delta$ -quasi component is a  $\delta$ -component. Therefore the statements (iv) and (v) are equivalent. The equivalence of (iv) with (i), (ii), (iii) follows from the fact that a set is  $\delta$ -open if and only if it is a  $\delta$ -neighbourhood of each of its points.  $\square$

**Corollary 4.5.** *A proximity space  $X$  is sum  $\delta$ -connected if and only if it is the far proximity sum of its  $\delta$ -components ( $\delta$ -quasi components).*

**Corollary 4.6.** *Let  $X$  be a sum  $\delta$ -connected proximity space. Then the map  $f$  on  $X$  is  $\delta$ -continuous if and only if it is  $\delta$ -continuous on each of its  $\delta$ -component.*

**Corollary 4.7.** *Every locally  $\delta$ -connected proximity space is the far proximity sum of its  $\delta$ -components ( $\delta$ -quasi components).*

**Corollary 4.8.** *If  $X$  is sum  $\delta$ -connected proximity space and  $U \subset X$ , then  $U$  is a  $\delta$ -component if and only if it is  $\delta$ -quasi component. In particular, If  $Y$  is a locally  $\delta$ -connected proximity space and  $X \subset Y$  is  $\delta$ -open, then  $U \subset X$  is  $\delta$ -component if and only if it is  $\delta$ -quasi component.*

*Proof.* By Proposition 4.4 (iv),  $\delta$ -components and  $\delta$ -quasi components coincide in sum  $\delta$ -connected proximity space. The last statement of corollary from the fact that every locally  $\delta$ -connected proximity space is sum  $\delta$ -connected;

and every  $\delta$ -open subset of a locally  $\delta$ -connected proximity space is locally  $\delta$ -connected.  $\square$

As in Example 3.5, sum  $\delta$ -connected proximity space may not be locally  $\delta$ -connected. But, if sum  $\delta$ -connected proximity space is  $\delta$ -padded, then it is also locally  $\delta$ -connected.

**Proposition 4.9.** *Let  $X$  be a sum  $\delta$ -connected proximity space and  $x \in X$ . If  $X$  is  $\delta$ -padded at  $x$ , then it is locally  $\delta$ -connected at  $x$ .*

*Proof.* Let  $N$  be a  $\delta$ -open  $\delta$ -neighbourhood of  $x$ . As  $X$  is sum  $\delta$ -connected, suppose that  $N$  is contained in  $\delta$ -component  $C_\delta$ . Since  $X$  is  $\delta$ -padded at  $x$ , there are  $\delta$ -open  $\delta$ -neighbourhoods  $W$  and  $V$  of  $x$  such that  $Cl_\delta(W) \subseteq V \subseteq N$  with  $V \setminus Cl_\delta(W)$  has only finitely many  $\delta$ -components  $C_\delta^1, C_\delta^2, \dots, C_\delta^n$ . Now for each  $i$ ,  $1 \leq i \leq n$ , there exist a  $\delta$ -quasi component  $Q_\delta^i$  such that  $C_\delta^i \subseteq Q_\delta^i$ . We show that each  $v \in V$  is in some  $Q_\delta^i$ . If there is some  $v \in V$  such that  $v \notin Q_\delta^i$  for each  $1 \leq i \leq n$ , then for each  $i$  we have  $V = (V \setminus Q_\delta^i) \cup Q_\delta^i$  with  $(V \setminus Q_\delta^i, Q_\delta^i) \notin \delta$ . Let  $W_i = V \setminus Q_\delta^i$  for each  $1 \leq i \leq n$  and  $M = \bigcap_i W_i$ . Since  $(V \setminus Q_\delta^i, Q_\delta^i) \notin \delta$  for each  $1 \leq i \leq n$ ,  $(M, Q_\delta^i) \notin \delta$ . Note that  $C_\delta \setminus M = \bigcup_i C_\delta \setminus W_i$  and for each  $i$ ,  $C_\delta \setminus W_i = (C_\delta \setminus V) \cup Q_\delta^i$ . As  $V$  is  $\delta$ -open in  $C_\delta$ ,  $(V, C_\delta \setminus V) \notin \delta$  which implies  $(M, C_\delta \setminus V) \notin \delta$ . Thus,  $(M, (C_\delta \setminus V) \cup Q_\delta^i) \notin \delta$ , that is,  $(M, C_\delta \setminus W_i) \notin \delta$  for each  $i$ . Therefore,  $(M, C_\delta \setminus M) \notin \delta$ . Therefore,  $C_\delta$  is not  $\delta$ -connected, a contradiction. Thus, each  $v \in V$  is in some  $Q_\delta^i$ . Therefore,  $V$  has only finitely many  $\delta$ -quasi components and each of them is  $\delta$ -open. Thus, each  $\delta$ -quasi component is a  $\delta$ -component. Hence,  $\delta$ -component of  $x$  in  $V$  is  $\delta$ -connected  $\delta$ -open neighbourhood of  $x$  contained in  $N$ .  $\square$
