> As for Scarpa, what is important was his capability and sensitivity in giving expression to materials; his ability to read into the very structure of the material in order to draw the greatest possible expression from it. Then there's also the great pleasure, the joy he derived merely from something well made.[13]

There is a remarkable photograph of Scapa taken while he viewed one of the sculpture installations at Castelvecchio.[14] This highly expressive photograph of Scarpa tells us much about the architect.[15] He has the stance of both architect and curator unifying two professions often at odds. Something of the spirit of the sculpture he was viewing penetrated his very countenance vivifying the brute material existence of the sculpture itself. The photograph shows the back of a robed sculptural figure in the foreground while Scarpa is in the background looking towards the unseen front of the figure while apparently glancing towards a colleague standing just outside of the frame of the picture. Scarpa is pointing downwards to the floor as if to confirm the correctness of the installation with a colleague that stands outside of the frame of the photograph. It is as if the sculpture and Scarpa were confirming each other's existence. Scarpa wore a long robe-like overcoat mirroring the garment on the sculpture. It is as if two 'expressions' were speaking to each other across the space of time. The sculpture raised off the surface of the floor on a simple plinth is spiritually and lyrically animated and awakened from its long night of material slumber.

4. MUSEO CASTELVECCHIO

It may be timely, especially in lieu of the primary topic of this conference – The Architect and The City – to reconsider one of Scarpa's most universally admired works - the Museo Civico di Castelvecchio developed across three periods spanning three decades (1957-64, 1966-1967 and 1973-1975). Scarpa's work at Castelvecchio stands as a high water mark of architecture as a form of expression. The project challenges the modern obsession for the condition of *tabula rasa* out which architecture miraculously appears seemingly out of nothing. The initial stages of Scarpa's interventions began in 1957 under the direction of the museum director Licisco Magagnato (b.1921 - d.1987) and continued until 1975. Most recently in 2017, the East wing rooms were renovated by the Veronese

[14] For a reproduction of this photograph see, Carlo Scarpa: The complete works, p.15.
[15] Since a photograph can be considered a kind of frozen slice of reality the question can be raised as to whether this form of technological reproduction can in fact capture the living and vital sense of expression in Croce's sense of the term. The question can be asked – Can Croce's idea of expression extend to photography?

architectural firm Bricolo Falsarella assocati. The brutality across much of Castelvecchio's history underscores the eloquence of Scarpa's interventions. Base expressions are side by side with rarified expressions.[16] Scarpa's unique expression at Castelvecchio broadly resides somewhere between Byzantine iconicity and Grecian lyricism.

In considering Scarpa's work at Castelvecchio it is important to realize that it was in settings of intense, rough and even brutal existing conditions that some of Scarpa's best work was produced. It is expression embedded *in-situ* or what could be termed a situated expression. Expression, like poetry, is not a problem to be solved but rather the unspoken conatus of the architect and the architecture.[17] When Scarpa had more free and open circumstances for expression he could at times become overwhelmed by the force of his own *maniera* and become Scarpesque.[18] However, within the gaps and fissures amidst the limitations of what he found present at Castelvecchio he was able to care for the place like a doctor. It was an extraordinary act of what could be termed expressive curation. The architect does not only curate as in safeguarding with great care all the contents of a museum but as architect *cum* curator innately expresses the curation across an entire project from the scale of hardware and individual installations to the *mise en scène* of building in the city.

Scarpa's successive work at Castelvecchio can be described as the restoration and renovation of an open wound in need of surgical care and reconstruction. This medicinal and ministerial act of restoration required an architect with the capacity to care for the buildings in great detail by taking on the role of a curatorial doctor not only for the Castelvecchio complex of buildings but the city of Verona. In a sense Castelvecchio is Verona. The castle and the city remain inseparable as if there is no real difference between 'architecture and the city'. Scarpa acts as the curator of the city, the castle and the river. For Scarpa architecture is a renovation of expressions past, present and future. Something must be already there in the form of architecture as a concrete expression. His best work innately intuits the existing conditions of expression in terms of what is found and what will be founded. The condition of *tabula rasa* is neither possible nor desired. In the beginning was the fragment and out of this, new layers of fragmentation heighten the feeling of an intensified expressionistic palimpsest.

Aldo Rossi's *The Architecture of the City* offered architects a way back into the city through the idea of affective memory rather than history per se. One could say the work of Scarpa is about memory as well but more precisely a form of remembrance of Verona. Rossi relied on a form of typological monumentality to bring the existence of the city to light and shadow. Scapa telescoped the city into his work through elaborately localized expressive and highly lyrical embellishments dispersed as fragments throughout the project. The word embellishment is selected as distinct from ornament to free the work to new readings and to offer it an aspiration towards musicality in Pater's sense that all art aspires to a condition of music. With Rossi one sees things best from a distance with Scapa the enjoyment heightens when one closes the distance only to be magnetically and magically drawn into its remarkable sway of expressive intensities. The unity of

[16] A colleague has perceptively remarked the significant damage inflicted on Castelvecchio during Allied bombing raids in WWII ironically gave Scarpa the opportunity to work on its rennovation. Prof. Steven Thomspon, personal communtiation (undated). On September 25, 1991 the Gold Medal for Miltary Valor was conferred upon Verona by the Republic of Italy in remembrance of the heroism occuring in Verona during WWII.

[17] There appears to be an unspoken and deeper ancient conatus (effort, endeavor, inclination, impulse) in Croce's thought about expression. The reader is referred to the entry on "conatus" in, Stuart Brown and N.J. Fox, Historical Dictionary of Leibniz's Philosophy (Oxford, 2006), p. 53. Conatus may be considered a presupposition of expression and expression as the externalization of an inner conatus.

[18] In this regard Scarpa's work amidst the intense existing conditions at Castelvecchio and the Fondazione Querini Stampalia in Venice are exemplary. However, in settings such at the Casa Ottolenghi in Bardolino it appears the expression has less limits to overcome creating its own stylistic universe much in the manner of F. L. Wright.

the place is caused by the capacity of these fragments to leap across space joining one to the other in a connective tissue. The spacing of the expressive conditions, more than mere details, allows them breathing room.

5. THE CANGRANDE EQUESTRIAN STATUE AS AN EXPRESSION OF VERONA

Of all the remarkable installations at Museo Castelvecchio Scarpa devised perhaps the most exceptional is the re-location and placement of the statue representing the Cangrande della Scala the child lord of Verona. Scarpa choreographed the museum and in particular the staging of the Cangrande sculpture as the quintessential symbol of Verona's past. The Cangrande was a member of the Scaligeri family ruling over Verona during the 13th and 14th centuries. Richard Murphy commenting on this installation writes, "…it is the most extravagant architectural setting in which to display a single work of art that has ever been created."[19] It is a kind of raised burial mausoleum suspended in the air like a hanging concrete garden.

The sculpture, sitting under an overhanging roof, is mounted on a high platform placed in a semi-enclosed exterior court at the end of a remarkable *enfilade* of five exhibition rooms. The statue and its setting is a complex crescendo to these series of rooms known as the 'sculpture corridor' and stands in a commanding position over the entire castle complex. The Cangrande statue, with its curious odd smile, lords over the Museo Castelvecchio as he did during his short but consequential reign from 1311-1329. The statue is significant because of the unique place of Cangrande in the history of Verona. The Cangrande hosted exiles from other cities and it is said he treated them with generosity and uncommon respect. The story of the young Cangrande imbues the sculpture with an importance it might not otherwise have if one only considers the sculpture itself.

It was this same statue, at that time in another location, John Ruskin made a series of exquisite drawings of during his excursions to Verona. The poet Dante Alighieri had visited the actual Cangrande during his stay in Verona and extoled his virtues in *The Divine Comedy*. He wrote of "the great Lombard who bears the holy bird upon the ladder…"[20] This is a reference to the family crest of the Scaligeri family. Displayed on the ground in the courtyard where the Cangrande sculpture is located resides a cast bell with this same symbol. Verona is a city of scalas or ladders where the stairs are more like ladders. Scarpa by the nature of this installation curated the history of Verona by expressing that history in the ladder-like monument to the Cangrande. Museo Castevecchio is a place of ladders and a distllation of the city of Verona itself. The sheer numbers of exceptional stairs cum ladders carefully placed throughout the museum are experientially staggering.

CONCLUSION: THE POST- LYRICAL CITY

It may be too late for the lyric tradition to have an efficacy in the architecture of the city hence the notion of the post-lyrical city. There is a need to save the lyrical from its total extinction and the road to its continuation is through lyrical expression. Is it proper to consider Scarp's work at Castelvecchio as post-lyrical? The literary critic Marjorie Perloff has written the lyric tendency in poetry had reached an impasse and saw in the later work of Ezra Pound and those that followed the beginning of a turn away from the lyrical towards a kind of intellectual poetry rather than an expressive poetry.[21] The expressive and emotive aspect of poetry was purposely held in abeyance.

[21] Marjorie Perloff, The Dance of the Intellect: Studies in the Poetry of the Pound Tradition, Ch. 8, "Postmodernism and the Impasse of the Lyric", (Evanston: Northwestern University Press, 1985), 172 – 200.

Perloff refers to Eliot's essay, "Tradition and Individual Talent", where Eliot states;

> Poetry is not a turning loose of emotion, but an escape from emotion: it is not the expression of personality, but an escape from personality. But, of course only those that have personality and emotions know what it means to escape these things.[22]

Despite Eliot's rather subtle admonition, it is clear Scarpa understood the limits of an unfettered highly personalized notion of expression. To paraphrase John Cage an artist seeks the expression of self rather than self-expression. The remote origins of the lyric reside in ancient Greek myths associated with the figures of Hermes and Orpheus.[23] We are told as part of the oral tradition of the Homeric Hymns Hermes invented the lyre and Orpheus was the first Greek poet and a virtuoso of the lyre.[24] We may recall for Scarpa the sway of ancient Greece was strong. Orpheus's music asserted its charm to the extent flowing streams would pause in the presence of such sonority. It is important to note in the myth Hermes meets the tortoise (soon to be lyre) at the entrance to his cave. There is a violent darkness associated with the orphic tendency that is particularly amenable to Scarpa's poetics at Castelvecchio best viewed under the cover of shade rather than under a full sun. A post-lyrical architecture suggests an architecture exiting from the threshold of the lyric, closer to the dionysian than the appollonian. As Hermann Broch has written in *The Death of Virgil* ; "…no song becomes lost that has ever plucked the strings of a lyre…"[25]

Could one view the city as a place of post-lyrical expression and the architect as the individual most responsible for actualizing this expression? Might the city itself fall under the umbrella of Crocian expression? This may provide new life for the idea of a city expressed as a work of art. To this end, the architect's responsibility is firstly aesthetic and secondly ethical. In his Noble Laureate lecture of 1987, Joseph Brodsky spoke of aesthetics as the foundation of ethics. In his words, "…aesthetics is the mother of ethics.[26] He adds we are aesthetic creatures before we are ethical ones. For Brodsky our moral compass is made possible and shaped by our fundamental aesthetic intuitions. He writes, "The more substantial an individual's aesthetic experience is, the sounder his taste,… the sharper his moral focus, the freer – though not necessarily happier – he is."[27] How many of us are willing to trade our happiness for our sense of beauty? In Brodsky's sense beauty and the expression that presses it into being offers a challenge to our happiness.

Brodsky raises important considerations for the architect working in the city. In positing his thesis Brodsky touched upon one of the most crucial dilemmas of our time – the tension between aesthetics and ethics. The city is the place where this debate is played out most significantly. The architect who does not cultivate and curate his or her aesthetic expression with precision and rigor leaves the city weaker aesthetically. This in turn leads to a weakening of the ethical dimension of a city. As Eliane Scarry reminds us "…beauty leads us to justice."[28] How do we as architects give expression to the justice beauty can lead us to? The city as aesthetic expression allows

the just and the fair to symmetrically extend in all directions like a perfect cube.[29] What is the just city we as architects desire to lyrically express? The fate of the city known as *Verona la Degna* (Verona the Worthy) rests upon on the worthy expression of the architect.[30]
Appropriately Scarpa was interred like the roots of a flower in a vertical standing position under a discretely placed horizontal grave marker at Brion-Vega in the city of his own death of which there can be no visitor among the living. This installation is an homage to the curatorial prowess and highly selective architectural virtuosity of Scapa. One is reminded of a single line from a poem by Charles Baudelaire, a poet Scarpa very much admired – "(For the deep grave is ever the poets friend)".[31]

ACKNOWLEDGMENTS

I want to acknowledge Emeritus Professor Sal Choudhury, a long time colleague of mine at Virginia Tech for his construcive and enlightened criticism. I also express my gratitute to Prof. Steven Thompson for his sympathetic and objective readings of later drafts of the paper.

PAPER #3.13

WHAT DOES A SINGLE BUILDING TELL ABOUT A CITY?

Burcin Basyazici[a], Birsen Sterler[a], Safak Cudi Ince[a]
[a]Yeditepe University, Istanbul, Atasehir

ABSTRACT

Ataturk Cultural Center (AKM) which was built in between 1946-1969, is considered one of the unique architectural examples of Turkish modernization period and stands out as one of the most controversial buildings in Turkey. Since it stands in Taksim Square, which is also considered as the main public square of Istanbul, the building has witnessed many to historical public events –including Gezi Protests- and has served as a showcase of the city by its meticulously designed façade.
However, the building was demolished in 2018. After a series of sterile discussions and protests, the government declared that AKM will be re-built again by the son of the architect who designed the original one. The new architect who is also a well-known architect of Turkey, declared that the façade of the building which has borne witness to an age, will be kept. This paper proposes to expose the architectural and urban history of AKM by confronting the concepts of the new and the old through the same building. AKM will be taken as a case to discuss the impact of a single building to the history of a city by focusing on the following questions; (i) what makes a building historical and iconic for a city? (ii) Can a *new* building represent the same meaning with *the old* even if the two have same function and façade? (iii) What are the effects of politicians and architects to urban memory? Even though *the new* building is under construction now, previous versions of the building will be presented through archival files and shared documents of the related architecture firms. The old and new press clippings will also help to understand not only historical and architectural but also sociological effects of the building on the urban memory.

KEYWORDS

AKM; Istanbul; taksim; urban memory; new-old; relation in architecture.

INTRODUCTION

The *new faces* the old is a promising and creative phrase by all its means, including architecture. Those kind of contention areas that faces two so-called incompatible ontological terms, have always a creative potential to ask new questions. If the case is architecture, the new can face the old in several research areas including restorations projects, urban planning, extension projects and etc. However, this paper does not concern these type of encounters and proposes to confront the new with the old through the same building, that is, Atatürk Cultural Center which has been renewed, re-imagined, reconsidered, and re-built many times in its short history. Ataturk Cultural Center (AKM) has a potential to help us to re-question what is new and what is old in architecture and to ask further questions on the power of a building in historiography of a city, as well. Therefore, it would be crucial to ask first; what AKM can teach us by focusing on the following questions; (i) what makes a building historical and iconic for a city? (ii) Can a *new* building represent the same meaning with *the old* even if the two have same function and façade? (iii) What are the effects of politicians and architects on urban memory? AKM is the most polemical building of Istanbul and Turkey. It is a unique example to understand how a building becomes historical for a city and interiorized and defended by professionals and civilians. This paper aims to question and understand the effect of a single building

in a city in terms of architectural, historical and political concerns. Since the building was demolished and is being re-built again, can we still call it a historical building or has it ever been this? What have changed during never ending debates it caused and what have those debates taught us as professionals? The historical development of AKM has been quite visible. It is often written in academic articles, newspapers and magazines. This study doesn't aim to re-write it's as-known steps again but to help readers to understand its unusual and unique position in Istanbul, the uncompleted history of AKM has been briefly mentioned in following section.

1. UNCOMPLETED HISTORY OF AKM

The history of the building dates back to 1930's and has still not concluded due to the everlasting design and construction processes. Its history began with a decision to build a contemporary Opera Hall in Istanbul to represent the contemporary lifestyle of young Turkish Republic back then. After this first decision of the Government, the first design agreement was made with a group of German designers in 1930 *(Cumhuriyet 1930)*.

However, it has been suspended due to WWII. When it had been put on the agenda again in 1946, the first proposal was designed by architects Feridun Kip and Rüknettin Güney by name Istanbul Opera. Due to budgetary savings of the government, construction was stopped and assigned to The Ministry of Public Works in 1953. Finally, in 1956 the Ministry have assigned architect Hayati Tabanlıoğlu who was a public servant in the same Ministry, to build a new project in Taksim (Can 2015). The building has been built in 1969 after twenty-three years long construction by name Istanbul Culture Palace and celebrated as an example of Turkish Modernization period. In 1970, the building nearly demolished due to a conflagration, and in 1977, it was reopened with the name Atatürk Cultural Center, which is still the name of the building today (Tabanlıoğlu 2010). AKM had done the honors of many national and international prestigious art events in-between 1977-2005. The building has also witnessed to the milestone protests in history of Turkey and the façade of the building had been used to hang protests' banners and posters. In 1999, AKM was registered as A-Class Cultural Asset by the second Preservation Board of Istanbul (*Istanbul Atatürk Cultural Center Directorate Briefing File 2005*). However, the Minister of Culture and Tourism declared the demolition of AKM in 2005 based on the idea that the building has concluded its lifespan (*Hürriyet 2005*). After a series of protests against this declaration, the building was not demolished however was closed. In 2008, the Government decided to restore the building instead of demolishing it. The Ministry of Culture and Tourism signed a contract with Murat Tabanlıoğlu who is the son of Hayati Tabanlıoğlu for a new restoration project (*Cumhuriyet 2012*). However, the restoration process has been stopped by order of 9th Administrative Court. In-between 2005-2018, AKM has been left as dilapidated and no one announced anything about the building despite the calls of Chamber of Architects and professional associations. During the process, AKM had witnessed the Gezi protest in 2013. During Gezi protest, today's president and the then prime minister of Turkey declared that AKM will be demolished and a new Baroque Opera Hall will be built in place of it. After a series of discussions and protests again, the President declared the new AKM project which is designed by Murat Tabanlıoğlu in 2017 and the building was finally demolished in 2018. Although it is declared that the new AKM will be completed in 2019, it is still under construction today in January 2020.

2. METHODOLOGY

To analyze AKM within the scope and the main arguments of the study, the building has been evaluated in terms of the crucial

breaking point of its history. Five periods were determined according to following features; (i) The 1st period in-between 1930-1956 correspond to the period starting from the first decision in 1930 by name Istanbul Opera to the Hayati Tabanlıoğlu's design of Istanbul Culture Palace, including the unbuilt proposals of the other architects who had been involved the process, (ii) The 2nd period in-between 1956-1977 corresponds to the period starting from the construction of AKM to the second opening of the building including the conflagration and restoration process, (iii) The 3rd period in-between 1977-2005 corresponds to the period when the building had served for its purpose and been used for many prestigious events, (iv) The 4th period in-between 2005-2009 corresponds to the period when the building had been closed and left as dilapidated, (v) The 5th period from 2009 till today corresponds to the period when the final decisions have been taken in a wide range of proposals including restoration, demolition and re-build. The building has also been left as dilapidated till its demolition in 2018 and still under construction for the new project today.

All five periods have been evaluated separately in following sections according to the main questions of the study with the help of captions in newspapers. The paper clippings helped to understand the whole process as it is officially announced in related years. For the first three periods, the original paper clippings and official gazettes have been used for main data to follow up the leading decisions and discussion on AKM. For the fourth and the fifth period, the articles which has been written by architects and/or columnists has been also used in addition to original paper clippings. Data have been firstly collected from *Tabanlıoğlu Family Archives* which has been donated to a research institute in Istanbul by name SALT. That archive has helped to collect photos and paper clippings in .jpeg format. The archive of *Cumhuriyet Newspaper* which is the oldest newspaper of Turkish Republic also helped to collect the old press clippings not available in SALT Research Online Archive. Articles and captions in other national newspapers also used for cross-check. To achieve the data; *AKM, Istanbul Culture Palace, Istanbul Opera* and *Taksim Theatre and Opera* keywords had been scanned through the archives in-between the years of 1930 – 2020.

3. WHAT HAD BEEN DISCUSSED IN 90 YEARS: AKM WITH PRESS CLIPPINGS

3.1. The 1st period in-between 1930-1956

1930 refers to the early period of Turkish Republic and the political approach of those years embraced the occidental lifestyle and improvements to carry the new Republic to future. It was also a break of from monarchical state structure of Ottoman Empire to construct the new democratic structure of Turkey. Ankara was –and still- the capital but Istanbul has always been in spotlight. Therefore, it was not surprising that the Government aimed to build a Theatre and Opera Hall in Istanbul instead of Ankara. Taksim Square has always been considered as the main square of Istanbul, and the Government organized an international competition for its masterplan. In 1937, the French architect and urban planner Henry Prost had been invited to Istanbul by Ataturk himself to design the masterplan of the city including Taksim Square and Gezi Park (*Bilsel and Pinon 2010*). At those years there was a mansion belongs to the Power Administration in the place where AKM has been built later (e.g. Fig. 1). The aim of the new Theatre and Opera Hall was to represent the new contemporary face of Turkey. That's why AKM has always been considered one of the most important concrete declaration of the changed system of government and therefore it has always carried a political approach. By referring to the article that

was published in Cumhuriyet Newspaper in 1930 (e.g. Fig. 1), the Government had an agreement with a group of German designers and it was expected to meet with them in Istanbul in the summer of 1930 for the new project. However, the project had been suspended due to the economic conditions of Turkey after WWI. In 1946, it has been put on the agenda again. Although the Government took the suggestions of French architect Auguste Perret for design, Feridun Kip and Rüknettin Güney who had designed many projects for the Government so far, designed the first project by name Istanbul Opera. Unfortunately, project had been halted till 1956 due to the budgetary savings of the Government. On the other hand, according to Murat Tabanlıoğlu, the last building, which was designed by his father in 1969, was still representing the traces of Kip and Güney's design (*Mimarlara Bülten 2013*).

In 1953, the project assigned to The Ministry of Public Works, and the Ministry asked German architect Paul Bonatz who was working as an instructor at Istanbul Technical University in those years, to proceed the design of Kip and Güney. Bonatz worked on some sketches for the building nevertheless none of those proposals had been built (e.g. Fig. 2).

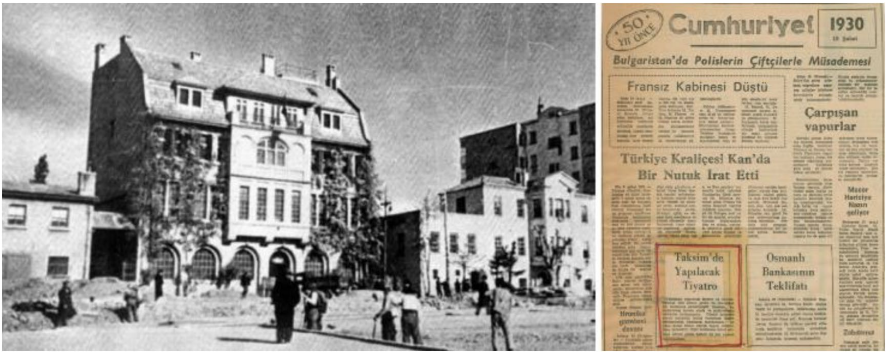

Figure 1. The Mansion in Taksim where AKM has been built later and the first paper clipping declares the new Theatre and Opera Hall in 1930. Source: (Salt Online Archive 2020)

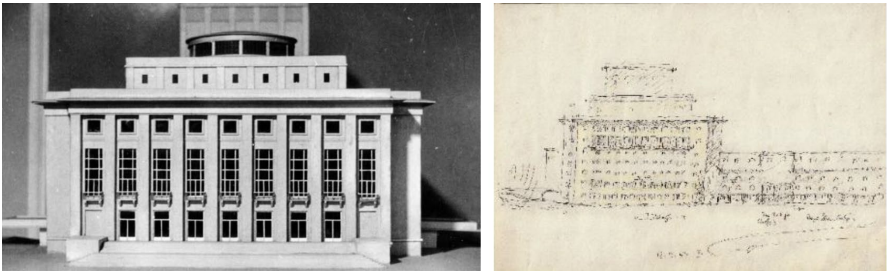

Figure 2. Model of the Istanbul Opera by Kip and Güney and Bonatz's sketches in 1953. Source: (Salt Online Archive 2020)

Finally, in 1956 The Ministry assigned Hayati Tabanlıoğlu to conclude the project but, he designed a new project that conserves the basic structure of Kip and Güney's design. For the 1st period in-between 1930-1956, very few press clippings are available for Istanbul Opera except the announcements of the process. This period had also witnessed an important political change in Turkey. In 1950, Democrat Party (DP) which is considered as one of the first conservative political party -although its name is democrat- had won the elections and Republican People's Party (CHP) –democrat although its name is republican- which is founded by M. Kemal Atatürk, had positioned as the opposition party. Even the major political approach of the county had changed, DP also embraced the Istanbul Opera as the monument of Turkish Modernization project.

3.2. The 2nd period in-between 1956-1977

When it was announced that Hayati Tabanlıoğlu was assigned to the project, the building was expected to be completed in the following years. As a matter of fact, Cumhuriyet Newspaper had announced two times, once in 1960 and second in 1961, that the building will be opened in these years (*Cumhuriyet 1959, 1960*). Those press clippings show that the society of Istanbul was looking forward to experience Istanbul Opera. One of the columnists in the newspaper even mentioned that every highbrowed human being in Istanbul may emulate to experience such operas in Europe and therefore Istanbul Opera is so crucial to allow them such kind of experiences in their hometown (*Felek 1965*). On the other hand, the building was concluded in 1969, after 9 years from the expected date. The press clippings which were collected from archive of Cumhuriyet Newspaper also help us to understand the construction process of the building took twenty-three years. It is clearly seen that; it was the budget saving to avoid the conclusion. A press clipping dated January 1958 shows that the legislator of CHP had accused DP to postpone the opening by saving insufficient budget for the construction for the proudly presented building (*Cumhuriyet 1958*). In 1969, finally the building opened by name *Istanbul Cultural Palace* with a grand opening ceremony. Since the program of the building was expanded for all branches of art not only opera, the name of the building has also changed. This alteration also caused a debate. According to Muhsin Ertuğrul who was the director of Istanbul Municipal Theatre, the building has been constructed for twenty-three years but naming took less than twenty-three days. He also said that palace is not an appropriate name for a contemporary Opera Hall and, also a contemporary country (*Ertuğrul, 1969*). Newspapers announced that opening as "the long-awaited Cultural Palace has finally been opened" (*Cumhuriyet 1969a*). Besides Hayati Tabanlıoğlu and the directors of art institutions –also artists and architects- the then President Prime Minister and even the Chief of General Staff of Turkey was attended the opening ceremony (e.g. Fig. 3). This can be interpreted as a declaration that what AKM means for Turkish Governors and politicians. Besides the supporters, there were also some critics about the building. Some important columnists of those years considered the building as a luxury consumption. While Barlas was pointing out that Turkey has bigger problems than having an international cultural palace (*Barlas, 1969*) and many other journalists was criticizing the elite events and their budgets (*Cumhuriyet 1969b*). The underlying approach of those critics was; the palace was built for just a few highbrowed people in Turkey and -because in that cultural era- opera, ballet and theatre is not a tradition for low-income society. Ironically, paper clippings in those years shows that the servants of surrounding Universities also protest the daytime schedules of the shows because they could not attend (*Cumhuriyet 1969c*).

Figure 3. The visit of Hayati Tabanlıoğlu, the then Prime Minister and senior staff of Turkey. Source: (Salt Online Archive 2020)

The building at the Pafos Gate consists of two main sections that are connected through a corridor over the street leading to the old city (Fig. 5). The north section hosts the entrance of the complex and a glassed exhibition space. The first floor hosts the private and semi-public research spaces accessible by the visitors. The façade panel openings adjust to the functional requirements of the corresponding spaces.

The building units at Sarayonu are positioned at the moat level of the city walls (Fig. 6). The main building section is situated below the street level, and extends on one side of the moat. Deployable units adjust through their size, structure and envelope elements to the functional disposition of the program. In this case the building primarily conveys open and closed spaces within the landscape at the moat level.

The façade of the building was another debate. It is still considered as an important example of contemporary Turkish architecture for architects and scholars. The façade had been designed by a well-known architect Aydın Boysan in corporation with Arçelik which was and still one of the pioneer international technology firm in Turkey. That's why their contribution to construction means a lot for architects to improve new construction techniques. The most important breaking point in the 2nd period is the conflagration in 1970 (e.g. Fig. 4). There had been many speculations on what caused that catastrophic fire, even some left-orientated organizations had been accused to sabotage the building. Some people who has worked for these organizations decreed by death sentence (*Son Havadis 1973*) and this also shows how AKM had been politicized during its history. However, it turned out that it was the electrical system caused the fire. The large part of the building was heavily damaged after the conflagration and the building was decided to be closed due to the need of restoration. It should be also mentioned that Turkish Armed Force staged a coup in 1971 and overthrew the Government. The outcomes of this politic event also blocked the restoration process. It had taken eight years to restore the building. A newspaper captioned that the restoration is going on at a snail's pace because it needs 25.000.000 TL while the budged of the Government is 15.000.000 TL (*Gün 1973*). In 1974, a columnist in Cumhuriyet Newspaper published an article titled File: Culture Palace to elucidate the ongoing process of the restoration. He declared that no one is taking the responsibility of the fire because everyone is so busy to share the tenancy of the Cultural Palace (Ketenci 1974). That everyone includes

the Government, the Municipality of Istanbul, the organization of State Opera and Ballet and Istanbul Municipal Theatre.

Another press clipping in 1976 shows that the construction workers also protested the Government for their unpaid salaries, and they declared strike for a month (*Cumhuriyet 1976*) and this also postponed the re-opening date. It is clear that the low budget was the first reason for delayed re-opening. In 1977, the citizens, reporters, organizations and professionals were at the end of theirs rope. A newspaper captioned that citizens have waited twenty-three years to build plus seven years to restore and now they are waiting for re-opening (*Hürriyet 1977*). In 1977, the building witnessed one of the most heartbreaking event of Turkey which is called *the bloody 1st of May*. Under the leadership of Confederation of Progressive Trade Unions of Turkey, 500.000 people gathered in Taksim for the celebration of the worker's day. The Union also covered the façade of AKM with banners. But unfortunately, 34 people were killed by a group of unidentified murderers by an open fire. The image of the building with that banner still represents 1st of May, 1977 and also still used as a reminder to emphasize the power of the working-class in Turkey. In September 1977, the building has been finally re-opened. However, the name of it had been changed again as *Atatürk Cultural Center* and this new name of the building could manage to survive till today.

3.3. The 3rd period in-between 1977-2005

The importance of the 3rd period is the only period that AKM had served as its purpose. It means that one of the most iconic building of Istanbul which has 90 years of history could be used only for twenty-nine years but still is the most important building of Turkey. During those years the building has also witnessed several government changes and also public events. The period in-between 1977-2004, there wasn't much thing to discuss about AKM within the scope of this paper. Only a columnist in Cumhuriyet Newspaper critiqued the abbreviation of Atatürk Cultural Center as AKM and he claimed that it is a political discourse of the conservatives, they do not want to pronounce the name of Atatürk on purpose (*Arpad 1979*). Another press clipping mentioned that AKM still has not an insurance for fire in 1980 (*Cumhuriyet 1980*). Apart from these, newspaper generally mentioned about the exhibitions and art events, not about the building. However, in 2005 the Government announced an unexpected declaration about AKM. The Minister of Culture and Tourism declared that AKM should be demolished because the building is not earthquake-resistant. The first reaction came from Istanbul Chamber of Architects. They declared that this proposal is baseless and illegal. Because AKM has

TAMİRAT KAPLUMBAĞA HIZIYLA DEVAM EDİYOR

3 yılda harcanan 15 milyona rağmen Kültür Sarayının çehresi değişmedi

Figure 4. A photograph of fire and the paper clipping after then. Source: (Salt Online Archive 2020)

already been registered as A-Class Cultural Asset by the second Preservation Board of Istanbul. However, AKM was closed again without any other declared reason but then it has been understood on following years that the Government has another agenda for Taksim Square. Many people blamed Justice and Development Party (AKP) for this declaration. Architects, artists, students, columnists, professional organizations and some politicians also supported Istanbul Chamber of Architects and the newspapers had started to caption about AKM again. Murat Tabanlıoğlu was also one of them who was against the demolition decision. He gave an interview to Radikal Newspaper together with his four colleagues titled as "Demolishing AKM? Don't even think about it!" (Aktuğ 2005). He also published an article in Radikal Newspaper in 2007 and said that "AKM is not just a building, it is an icon" (*Tabanlıoğlu 2007*). However, he gave up his critical position in later years and has been announced as the new architect of the new AKM in 2017.

3.4. The 4th period in-between 2005-2009

This period corresponds to the second period of AKM that had been kept close. During these four years it was not clear if AKM will be demolished or restored again. In 2007 Cumhuriyet Newspaper caption that AKM should be restored instead of demolition and added that it is a God-given right of art lovers in Istanbul to interpose the demolition. At the same page the newspaper also features the declaration of Istanbul Chamber of Architects titled as AKM shouldn't be demolished, it is one of the most unique example of Turkish Republic architecture and also the symbol of Taksim Square (*Cumhuriyet 2007*). Within these four years many protests had been organized by artists and architects. The Government was in the cross hairs of all these protests. A columnist in Radikal newspaper published an article about AKM titled as "AKM and Memory Removers". He emphasized that it is not important if you like or don't like the architecture of AKM but still to demolish it means to remove one of the most important heritage of 20th century history of Istanbul and the modernization period of Turkey. He also added that who is Istanbulian, has also a memory about AKM. If you demolish it, you will also demolish those memories and none of the buildings can replace those memories even if it will be the most beautiful building of the world (*Şahin 2007*). In 2009, the Government declared that AKM will be restored and the restoration project has been assigned to Tabanlıoğlu Architects which means Murat Tabanlıoğlu. It was not surprising to think that Murat Tabanlıoğlu wants to restore the building which is designed by his father to keep it out from demolition. The restoration project has been accepted by the Preservation Board in 2009, however in the same year the Union of Culture and Art indicted the Ministry of Culture and Tourism by justifying the verdict of A-Class Cultural Asset (Tabanlıoğlu 2013). Although Istanbul 2010 European Capital of Culture Agency Executive Board tried to arbitrate, the Union didn't withdraw the case and the 9th Administrative Court decided to halt the decision of restoration.

3.5. The 5th period in-between 2009 till today

From 2009 to 2017 there have been no official news about the future of AKM, will it be demolished or restored. In 2009 the Government allowed the 1st of May ceremonies to be held in Taksim Square again and in 2011 the Confederation of Progressive Trade Unions of Turkey hold the same banner on the façade of the AKM after 34 years to remind the *bloody 1st of May* in 1977 (*Cumhuriyet 2017*). 2013 is also another important year throughout the history of the building. Thousands of people in Istanbul had protested the decision of demolition of Gezi

Park in Taksim Square. The protest held in in Taksim Square again even it was not allowed by the Government. The Government tried to disperse the demonstrators by police force however it took nearly one month to end the protest. National and international press announced this as "Gezi Protests in Taksim". Throughout the protest, AKM has taken to the stage again. Although the building was closed on that date, protesters used the façade of the building again as a screen and representation of the event (e.g. Fig. 5).

During the protest the president of Turkey announce that not only Gezi Park but also AKM will be demolished. He also proposed to build a baroque style opera hall in place of Taksim. This proposal was also caused a debate among citizens and professionals. Istanbul Chamber of Architects published a release to the public and claimed that the demolition of AKM will be illegal and it is not understandable to demolish one of first Modern project of Turkey to build a baroque style building instead of it. In 2015, another debate occurred related to the façade of the AKM. The Ministry of Culture and Tourism covered Turkish Modernism' iconic façade with a movie poster that, the Movie about Ottoman Empire. It was the first time that one of the most important public square of Turkey had been represented by a movie poster and it was also the first time AKM had been used as an advertising board. In 2016, *World Architecture News 2015 Awards* announced a project which is designed by Adrian Smith & Gordon Gill Architecture awarded as *Future Project Civic Building*. It was a surprising disclose for Turkish citizens because the building was designed in place of AKM. The newspapers announced this news as "the mysterious project" (Cumhuriyet 2016). It is still a mystery for all that who ordered the building and in which purpose. However, this project has also never been built (e.g. Fig. 6).

Figure 5. The façade of AKM in the bloody 1st of May 1977, same banner in 1st of May 2011 and Gezi Protests in 2013. Source: (Cumhuriyet 1977, 2017; Sözcü 2013).

Figure 6. The façade of AKM as advertising board in 2015 and the "mysterious project" in 2016. Source: (Cumhuriyet 2015, 2016)

Finally, in 2017, the Government announced the new AKM project with the participation of the Ministry of Culture and Tourism, the governor and mayors of Istanbul and Tabanlıoğlu Architects. The project was introduced via a video including 3D renders of the new design. The new AKM is completely designed by Tabanlıoğlu Architects under the leadership of Murat Tabanlıoğlu. as far as it is understood, the old and famous façade of the building has been kept and it is the only thing that has matched with the original AKM. Now besides all the memories, *the new* AKM will also face the old with its façade physically. In the opening speech of the ceremony, the President of Turkey declared AKM as an unfortunate building. According to him, there is an institutionalized lobby in Turkey which is also supported by foreign agents. That lobby has been trying to sabotage every urban decision in Turkey just because political reasons. To him, they used AKM as a tool to protest the Government and the only reason that the building has been kept as a ruin for 10 years was the acts of this lobby (*Hürriyet 2017*). The President also considered this *lobby* in the same equation with advocates of the terror in Turkey and he also declared this again in the groundbreaking ceremony of the new AKM in 2019 (*CNNTürk 2019*). The design of the new AKM and Murat Tabanlıoğlu is still a very controversial subject in current days. Since Murat Tabanlıoğlu was one of those who strongly opposed the decision of demolition in 2005, those critiques were not unexpected. Hereupon, Murat Tabanlıoğlu answered those critiques via an interview he gave to Financial Times in 2019. He said that "normally, I would never collaborate with the Government however AKM is a family inheritance for me". Nonetheless, he added that he was so upset the day the building had been demolished and could not even watch or see it (*Financial Times 2019*). In the groundbreaking ceremony, the President declared the building will be opened in 2019 however today in August 2020, the current situation as in figure 7.

CONCLUSION

AKM with its unique history has been representing the role and the debates of architecture in a contemporary society in many perspectives. Within the scope and the questions of this paper, it contains all answers as a cumulative case. What makes a building historical and iconic for a city? The answer would be the architectural design as it is in this case. AKM was one of the first examples of the Turkish Modernization in architecture, it would be also the historical events that the building had witness and AKM has always carried this responsibility throughout its history. The answer also would be the landmark features of the building; AKM

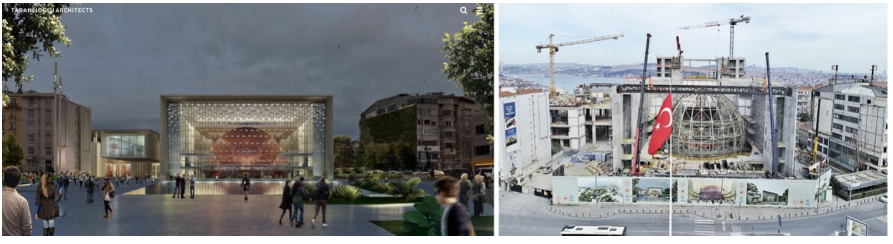

Figure 7. The new AKM project and the current project site. Source: (Tabanlıoğlu Architects 2020)

is placed in the most important public square of Istanbul. However, beyond those answers AKM is historical and iconic because it has always been a battlefield of ideological struggle between modernist revolution and the conservative counter-revolution. This directly leads us to the 3rd question: What are the effects of politicians and architects to urban memory? Even the citizens of Turkey who had never visited Istanbul know many things about AKM. It has created a kind of cumulative urban memory for all Turkish citizens. While some of them strongly against its demolition the others celebrated the new building. When it is considered that it is just a cultural center, this separation becomes much more interesting for architecture. Besides the politicians who has participated the process as decision makers, when current Turkish President claimed people who protested the demolition as terrorist, AKM also became a terror weapon that causes public indignation and this is the answer what are the effects of politicians on urban memory. It is understandable that architect Murat Tabanlıoğlu has wanted to design the new building to adopt his father`s legacy. He is neither politician nor decision maker. However, he has also been accused of betraying the urban memory, and this is the role and the effect of the architect in urban decisions. He was expected to conserve an architectural legacy and the urban memory, so the architect became a political figure and/or a savior instead of a professional. AKM also shows that if a building becomes an urban legend no matter if it is new or old. Possibly, the new AKM will be more functional and well-designed according to the original one however It is not the design that causes the debate in here, it is the memory that a city needs. Thus, when the new AKM will face the old, it will also represent the demolition of the original one, but still will be historical and iconic again. The 2nd question of the paper is still open to discussions. Since the building has not been completed yet, it is not appropriate to answers this question. Future discussions will show us can a *new* building represents the same meaning with the old even if the two have same function and façade?

PAPER #3.14

THE URBAN CHURCH: REPURPOSING A COMMUNITY DETAIL

William O'Neil Bourke[a]
[a]Temple University, Philadelphia, Pennsylvania, USA

ABSTRACT

What is the status of urban churches today? Changes in congregations and notions of community are causing the abandonment of urban religious structures. As cities change, so do their architecture and communities. This results in urban churches becoming a popular focus for redesign.

The common trend for church redesign--Christ Reformed Church (Philadelphia) and First Baptist Church (Dayton, Oregon)--shows approaches for housing and restaurant space, respectively. Though they seem to be reasonable solutions, they lack the connection to traditions of community embedded in these structures.

This paper looks at the challenging design for hyper-specialized architecture. Through historical research, detail, and respect, the paper proposes how church architecture adaptive reuse should respond to the originality of these sacred spaces. Design should take into consideration adaptive reuse trends of contrast (new vs. old) to architecturally create new buildings with revitalized community purposes.

The design case study it analyzes is the Church of Assumption BVM at 12th and Spring Garden in Philadelphia, PA. Being a Gothic Revival cathedral, the design focuses on not just the space, but also, the sublime experience of the church itself. The design calls to reinvent the way the public interacts with these buildings by changing the procession of space. Since Gothic art was considered an act of devotion, the project, *Art as an Act of Devotion*, adapts and reprograms the space as an artist collective where community members can come to create and experience art in a neighborhood lacking public space.

By introducing site connections that form new geometries (contrast), changing notions of entrance (transparency), and creating new experience through moments of reflection (prayer) and movement, adaptive reuse of churches can begin to respect, reinvent, and revitalize buildings and their communities within the city.

KEYWORDS

Adaptive reuse; new meets old; contrast; urban churches; gothic architecture.

Figure 1. The Church of the Assumption BVM. Philadelphia, PA. Source: (Bourke 2019)

INTRODUCTION

"*The True Church can never fail. For it is based upon a rock"* (Elliot 1917, 27-8).
Throughout history, churches have been gathering places for communities. These structures stood as symbolic representations of spirituality, community, and tradition. They are used for big congregations, pilgrimage destinations, and daily prayer. Yet, in today's changing urban dynamics, they are beginning to lose the purpose of their original design.
Research has shown that churches are primarily affected by changes in their congregations.

> "Far from being fixtures in the urban landscape, the population of congregations is a constantly shifting array--some coming, some going, others moving and still others reinventing themselves" (Simons, 2017 12).

This makes congregations "drivers of change of sacred places" because the changes like "births of new congregations, deaths of existing congregations, contractions and expansions of existing congregations" affect the groups and function of churches themselves (Simons 2017, 12). As communities grow and change, the groups shift and move to different buildings, consolidate from multiple to one, and leave others as a result. The dynamic changes cause the abandonedment of urban churches while their communities develop new needs. The result leaves urban churches with no congregation to serve and creates an infrastructure with no purpose.
The question then becomes why save these buildings? Aside from being beacons for community, they are examples of sublime detail and beauty worth saving. John Milton wrote:

> "But let my due feet never fail/To walk the studios cloister's pale,/And love the high embowed roof/With antique pillars massy proof,/And storied windows richly dight/ Casting a dim religious light" (Milton 2012).

As houses of god, these churches were designed with care and high craft. The spaces they create have an air of spirituality. Architect Steven Holl often talks of the feeling of a place. Holl states,

> "A five-year-old can walk into a building and not really understand the concept, but still get that feeling" (Phaidon (Holl), 2019).

It is the indescribable effect of walking into a space and being struck by an unconscious feeling of awe and beauty that makes one remember a building. Most urban churches do not have to strive to become special spaces because they already embody both the tradition of craft and service that we unconsciously appreciate through our nostalgia towards history and memory (Zumthor 1998, 7). This paper broadly looks at the dilemma of urban church architecture and then focuses more specifically on the Gothic and Gothic Revival building type to propose an interdisciplinary solution to the design problem of respecting these buildings but revitalizing them with new purpose.
The adaptive reuse process will be explained through a design case study that focuses on the Gothic cathedral type and the experiences its architecture creates. Their ornament, their play with light and shadow, and the connection to the spiritual, create an example of awe and stunning architecture that new construction fails to achieve. Church sublimity combined with a community function prove that churches have valuable and unique characteristics. Even though they have lost their institutional purpose, that does not mean the building must lose the qualities that make it special.

1. COMMON USES, REOCCURING ISSUES: HOUSING, RESTAURANTS, AND PERFORMANCE VENUES

With their current uses for abandoned ecclesiastical architecture, designer's approaches fail to preserve the beauty of these spaces. Designs include bars, housing, restaurants, and performance spaces. Cities have many adaptive reuse projects of churches, like Christ Reformed Church-Chapel Lofts (Philadelphia) and the Sheba Apartments, Fishtown (Philadelphia) and First Baptist Church-Block House Cafe (Dayton, Oregon), to name a few. Though these are profitable solutions, they fail to create a connection to the tradition and service-oriented function that churches were designed for. All current reuses *devalue* the sacred, *degrade* the institution, and *restrict* the accessibility of these urban churches.

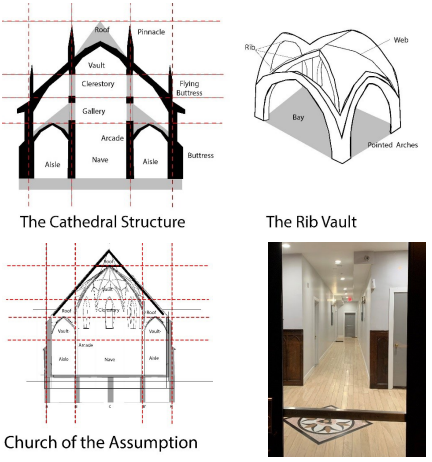

Figure 2. Gothic Church Spatial Diagrams (left), Front Door, Sheba Apartments (right) Source: (Bourke 2019)

Housing design *devalues* the sacred nature of a church. Instead of being a holy "house of God", these buildings lose the sublime by becoming an "apartment for rent." The designs lose the dichotomy of big lofty spaces of the nave, and narrow aisles that shape the spatial integrity of a church (Fig. 2 left). This special and unique spatial organization becomes segmented and fractured to fit in as many rooms as possible and in doing so, destroys the interior dynamics of these churches. By doing this, churches lose their ability to be used for reverence and reflection. Their aspect of awe and emptiness is missing. Located in Fishtown, Philadelphia, Sheba Apartments, was repurposed as apartments, and looking through the front door, it already becomes apparent that there is a change in spatial organization (Fig. 2 right).

Other attempts, like restaurant reuse, degrades the character of the institution of the Church. Rather than being a building for public service the building becomes a business or "profitable" enterprise. Capitalizing on the big open spaces, the approach crams as many tables into a large space with disregard to the original programmatic intent. The nave becomes cluttered with tables and chairs and the institution shifts away from its service-based focus (Fig. 3). The reuse does little to change the space and approaches the "redesign" as a chance to fit in whatever furniture they can based on a square footage count.

Figure 3. The Church, Dublin, Ireland. Source: (The Church (Management) 2017)

The performance venue approach, like The Old Church (Portland), appears at first to be a more viable use but has its shortcomings as well (The Old Church (Management), 2019). This effort restricts accessibility and becomes an issue of "day and night." The design questions the fundamental nature of church-goers needing access to building throughout the day. The adaption becomes a venue operated only at night and no longer offers solace for daily prayer losing its communal purpose. They revitalize the building with new function similar to prayer—performance—which appears to speak to the fact the churches were meant to be big, beautiful, and acoustic spaces, with a large area for gathering. However, this approach narrowly responds to the church architecture and removes the interaction and connection to the building and its details. Performance reuse successfully creates an experience where the participant can interact with the performance (like mass service) but fails to connect the architecture as an active facilitator in its function. Venue plans remove accessibility and the building becomes a shell in which a performance occurs rather than an active contributor to a spiritual experience.

All three types are options, but can church adaptive reuse become something more? New design should reflect the originality of these buildings. Current uses fail to respect the social responsibility that these buildings were created for. By using a method like historical analysis of church design, we can learn to find more appropriate ways to redesign these buildings.

2. METHODOLOGY: RECONNECT AND RESPECT THROUGH HISTORY AND TRADITION

To better grasp design solutions for the urban church, one must understand the history and development of the design of ecclesiastical architecture, and more specifically, Gothic architecture. History can give lessons on how to create more meaningful connections within architectural design by connecting these existing buildings to their roots. Gothic cathedrals were designed with two community-based functions in mind: pilgrimage and the daily purpose of prayer. The fundamental basis of a church design was its programmatic intent to serve the community (Monrose 2012). The architecture was a public space representing a religious institution but meant to be open to all. The program was defined by civic duty, and its beauty was a representation of craft and a call to something greater—a sense of spirituality. To understand these buildings, we must understand their history, as well.

History gives clues to the origins of cathedral architecture. In the Gothic era, art [and architecture] was seen as an act of devotion (Homan 2016, 50). In response to what some saw as the degradation of society, Gothic Art was a mode for uplifting and improving the state of the community and society in general (Homan 2016). Gothic architecture embodied this message, and the relics and the buildings were designed with the intent to create moments of deeper connection for personal prayer and reflection.

The architectural design of these churches was carefully laid out to serve its function. Tracing the history of a church, from a Roman basilica to the Gothic Revival cathedral, shows how its service-oriented function formed its architecture (Fig .4). As mentioned, the Gothic cathedrals were designed as pilgrimage churches with the architecture of the nave, apses, and ambulatory simultaneously facilitating prayer (Stalley 2007). Religious service or mass also shaped the architecture, as the two functions could occur together. The functions led to the development of the church to have a conflicting dynamic of movement and meditation that created the unique spaces found in cathedral design.

These spaces allowed for people to move freely and find their own personal moments for reflection even during mass. This gave churches a purpose as a space of devotion, reflection, and beauty for the community (Homan 2016). The uniquely orchestrated procession of spaces creates a sublime architectural experience of active and static moments centered around prayer and reflection.

2.1. Methodology: Themes of Contrast (New vs. Old)

The adaptive reuse projects call upon one important concept of transformation from new to old, which is contrast. Liliane Wong mentions that "Adaptive reuse, in contrast to demolition and preservation, perpetuates a continuum of growth and change" (Wong 2017, 35). Adaptive reuse is founded upon the

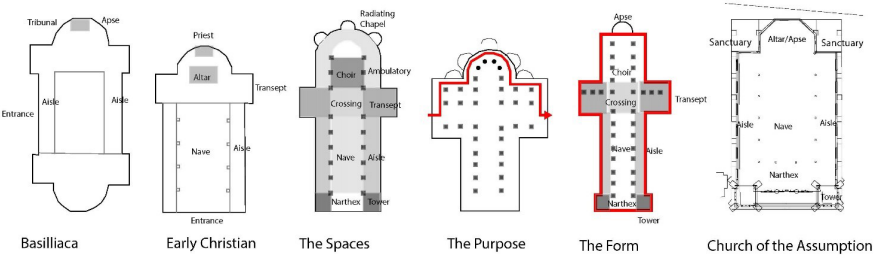

Figure 4. The Historical Development of Church Architecture. Source: (Bourke 2019)

To respect and redesign a sacred space calls on a sensitivity to the original intent, tradition, and beauty found in religious architecture. When designing these spaces, there are special difficulties that arise because the architecture is so specific. How does one design a new adaptive function for a building so focused on its programmatic intent for religious service? The other question is how to create a dynamic change while respecting the originality, spatial organization, and beauty of the church? The solution comes with three foci: community (program), contrast (tectonics), and sublime experience (design approach). To respect the original design, the reuse must maintain its community function. In addition, the reuse will focus on recalibrating the sublime experience, which is the aspect of the design reliant upon the original notion of movement and reflection or procession of spaces. Lastly, the design will call for the contrast of new and old to architecturally state the changing function.

notion of change. Architecture must respond to the changing notions within a community and adapt to fit new needs. As mentioned, churches are facing a period in which they are losing their original function for prayer, so they need to adapt or find a new purpose. The tectonic architectural response to create new functions is through the process of contrast.
Charles Blozies states that adaptive reuse projects require an element of contrast. With adaptive reuse, there should be a response within the architecture that enhances "our appreciation of both new and old" (Blozies 2011, 139). He further breaks down the notion of contrast into three categories: extreme, reserved, and referential. With *extreme* projects, like Daniel Libeskind's Contemporary Jewish Museum, Blozies shows how new alien-like structures can completely redefine old spaces through the introduction of new geometries (Blozies 2011, 94-5, Fig. 5). With *reserved* contrast, found by Renzo Piano's

Morgan Library, Blozies illustrates how architectural interventions can be simple and austere. The design unites three buildings from three different eras of design history with a simple connective tissue forming a new complex (Blozies 2011, 98-9, Fig. 6). With *referential* contrast, like Forte Di Fortezze, Blozies shows how collective architecture can use contrasting materials to create connections that artfully respond to the historic complex and create new passages and routes through the existing building (Blozies 2011, 80-1, Fig. 7). Through all three modes of contrast, adaptive reuse can create new spaces through a varying dialogue between new and old elements to reinvent and revitalize existing architecture.

Disregarding the degrees of extremity, all three projects hold one thing in common, the element of contrast. Whether it's glass and

steel against stone, or metallic panels against brick, or steel infiltrating granite, contrast can be used to call attention or notify that there is something new and different within the old architecture. With architects like Viollet-Le-Duc and Louis Kahn, contrast becomes an element that contributes and improves the existing architecture. The connections to "the nature and tradition of a space...and the ideal..human aspiration"(design) show how architecture can respond to what exists rather than ignore it (Bressani (Le Duc) 1989, 327-350). The design case study's approach at the Church of Assumption B.V.M. in Philadelphia, learns from all modes of contrast and looks to create a new architecture that redefines the existing site while paying attention to "the nature of a space..and the will to exist a certain way" (Wong 2017, 35). The proposal shows how interventions can respond to and respect the building and not destroy the integrity and tradition steeped within the beauty and experience of its space.

3. CONTEXT: SPRING GARDEN COMMUNITY

The design case study for the adaptive reuse of an urban church focuses on Church of the Assumption BVM. The church is a Gothic revival building located in the heart of a changing area of Philadelphia, Pennsylvania. Philadelphia has become a hot bed for the dilemma of abandoned church infrastructure. As a city, Philadelphia is built on the foundations of religious freedom, and as one of the largest cities in the United States, the population has been affected by the flux of congregation demographics.

The Church of the Assumption B.V.M. is in the Spring Garden District of Philadelphia. Recently, the area has been rebranded as the Spring Arts District. It lies in an old industrial part of the city, and has an architectural variety ranging from warehouses, to row homes, to abandoned railways. As a major component of adaptive reuse, the Reading Viaduct, an abandoned railway, has been planned to be repurposed as public greenspace, and as a result, it has sparked incentive for redevelopment of the area (Saffron 2018). With a promising architectural landscape, the area's adaptive resue face the problem of serving a new complex demographic

Many projects only offer an activation of the area at night in the neighborhood. With large populations of homeless people, and the call for redesign of forgotten industrial infrastructure, the area has become popular for adaptively reused buildings like performance venues and breweries (Flynn 2017). Through the process of redevelopment, the creative class is drawn to the area because of its affordable options for artist spaces, which creates an incoming demographic of young creative professionals. The tension between the new incoming population and existing area offers an opportunity for a new community space that can be focused on the arts, performance, and outreach.

Looking at the urban demographics and development, the Art as an Act of Devotion project looks at redesign within the context of its emerging community. With new artists and existing outreach, the adaptive reuse design case study looks to serve the community through a new artist collective where the community can come to make, teach, and connect communities through art. A building created through devotion and art, can be repurposed to serve and revitalize a community through that same devotion.

4. CASE STUDY: THE CHURCH OF THE ASSUMPTION B.V.M. (PHILADELPHIA, PENNSYLVANIA)

The case study, *Art as an Act of Devotion*, looks at the site bordering 12th and Spring Garden. The Church of the Assumption BVM adaptive reuse looks at redesign through elements of contrast, community, and the sublime. The site

includes three religious buildings: the rectory, the convent, and the church (Fig. 8, 11). The buildings are situated neighboring each other and packed tightly together creating spaces that recall the narrow streets and towering masonry buildings of a Medieval city (Fig. 11). The focus of the redesign connects the support buildings and the church to create new spaces for outreach, residences, and studios. By introducing connections between all three buildings, the design calls for an activation of the whole site rather than one building. The artist collective becomes a dialogue for community by creating a complex for public service.

The adaptive reuse proposal focuses on two key elements: creating new viable connections, and fostering the growth of a new community. The connective tissue called the "cloister" encloses bridges between the three buildings making the complex. The bridges then connect the inside by creating new routes on the second floor or "gallery" level. These links are formed by joining the existing and adjacent masonry openings--like windows and doors—of the buildings. The design reinvents, redirects, and reorients the buildings with new routes through the three buildings that offer new interior geometries in the church (Fig. 9). Newly formed connections

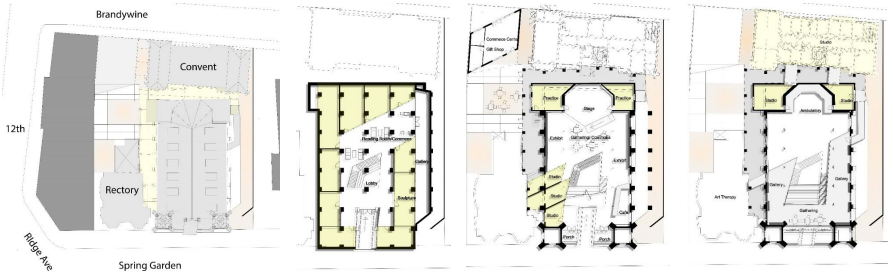

Figure 8. (From left to right) Site Plan, Basement, First Floor, and Gallery Level. Reference. Source: (Bourke 2019)

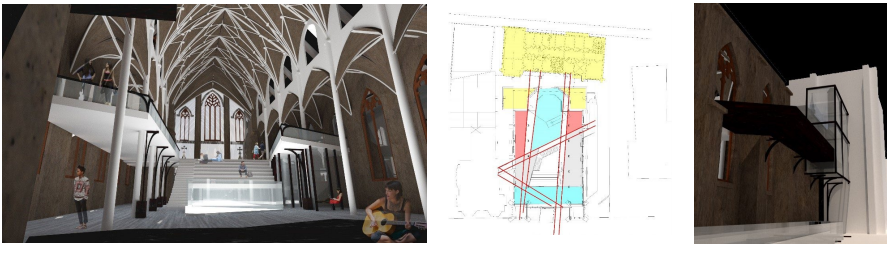

Figure 9. Church Interior (left) Regulating Site Lines and Openings (center) Cloister (right). Source: (Bourke 2019)

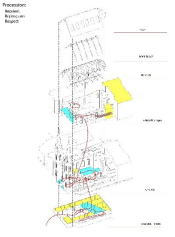
begin the dialogue of contrast of the new and the old.

The adaptive reuse implements all contrast types proposed by Charles Blozies. Like Forte di Fortezze, the bridges themselves are *referential* as they respond to the "raw form and structure" of the existing buildings. They solve the "practical problem" of how to connect these three closely knit buildings. In addition to form and structure, the bridges also refer to the industrial past of the area with the material choice of galvanized steel (Blozies, 80). These bridges then actively introduce new extreme geometries. Like Daniel Libeskind's Museum, these geometries are "unsettling and vertiginous" and they notify the shift from old to new by forming new interior spaces (Blozies, 94). Lastly, the cloister connects three startlingly different buildings with a simple reserved response tectonically (Fig. 9). Made of steel and glass, it is constructed with a mesmerizing "rhythm of new and old" in an "understated" manner like Renzo Piano's Library (Blozies, 99). The design does so with regard to material and scale. The glass enclosure allows light into the interstitial space that is wedged between the three buildings. The cloister itself does not reach higher than any of the three structures and allows the church to remain as the focal point of the complex. The proposal creates a complex that calls to serve a new function and design through the technique of contrast.

The design decisions call to breakdown the hierarchy of tradition encompassed in these structures through a focus on concepts of transparency and entrance. The front façade gets modified from stone to glass, which makes the interior always visible to the public (Fig. 10, 11). The design creates street view that establishes the church as a lantern for its community activating it with different programmed areas like classrooms, exhibits, studios, and practice spaces. The new program for the building begins to bring activity to the Spring Garden corridor throughout the day. By doing so, the building breaks down the barriers--institutionally and physically--that seem to be arising between the community, the church, and its architecture.

After inviting the public into the newly repurposed collective, the next step was to change the procession of space (sublime experience) by recessing the entrance into the building and submerging it below grade. This shifts the entrance from going up to going down, and it reactivates the unused basement of the church for new studio spaces and a lobby. The new entrance into the church from the basement allows for a dramatized entrance into the nave of the church (Fig 10). By opening the basement to the nave, the design amplifies the height of the nave space, and reorients the experience of the space by drawing the viewer to look up at the decorative rib vaulting when entering the church. This begins to touch on



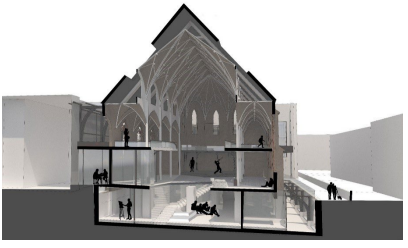


Figure 10. Community Lantern (left), Sublime Procession (center), Section (right). Source: (Bourke 2019)

the importance of redesigning the spatial sequence that becomes the driving force for design (Fig. 10).

The design approach calls for one to design with respect to the integrity of the space and the institution of the church. What gets redesigned in this approach is not quite the building itself but rather the interaction with and procession through the spaces. Elements of contrast, connection, transparency, and entrance, work to respect, reorient, and reprogram the church. By introducing bridges and changing the entrance, the design changes the movement through the building. With new program and geometries, the building becomes activated with a new function and architecture. (Fig. 10) From a building built upon prayer, mass, and movement, it gets reactivated regarding that original function. The Art as an Act of Devotion adaptive reuse calls for the community to reexperience the church through a newly activated spiritual framework for the religious structure. As people come to create, learn, and experience art, the church naturally provides spaces and places where they can participate, reflect, and grow through a community arts-based program. The design proposes to respect religious tradition yet offers a space and opportunity to serve new community needs that its original design no longer can.

CONCLUSION. RECREATING MEANING BY LEARNING FROM TRADITION

Looking at the history of the institution of the church and the original design intent, we can learn how to respect and celebrate church architecture. Looking at Gothic Revival churches and their history, designers can use approaches like sublime experience and meaningful public purpose as a guide to adaptive reuse solutions. By doing so, architects can repurpose these buildings in a manner that does not ignore the beauty, integrity, and spirituality of the space. Church architecture is steeped in tradition and conflict as a house for a religious institution. That does not mean that redesign solutions should ignore tradition, but instead, it should embrace it. When redesigning, architects will run into issues because these buildings are connected and revered by the communities due to the fact, they were created to serve them. It is the tradition and community service that should remain as an integral part of design for these structures. The problems arise when community structures are demolished or redesigned, and the original function ignored.

Can we respond to what is there rather than destroy what exists? The hyper-specialized spaces are designed with spatial relations and feelings that must be preserved. Rather than looking at fracturing these buildings or packing them with furniture, we can celebrate them and their history. Urban Churches not only serve as an interesting topic for redesign, but also offer lessons to design in general. They offer opportunities to work with architecture

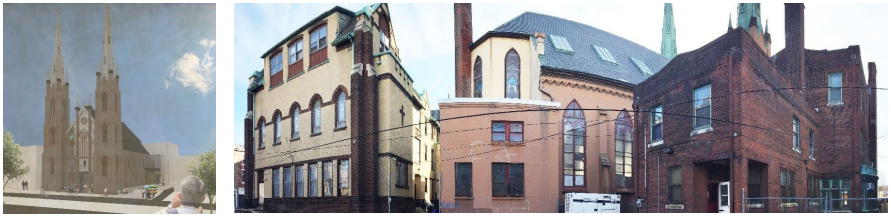

Figure 11. Art as an Act of Devotion (left), Site of Church of the Assumption BVM (Left to Right: Convent, Church, Rectory). Source: (Bourke 2019)

already steeped with meaning and tradition. There is a need today for designers to create architecture that has a deeper meaning and significance. Architecture that was created with fundamentals in history, tradition, the sublime, and public service is an architecture worth saving.

PAPER #3.15

NEW OLD CITIES.
THE REBIRTH OF GERMAN HISTORICAL CENTERS

Michele Giovanni Caja[a]
[a]Politecnico di Milano, Milan, Italy

ABSTRACT

The rebirth of historical centers in some important German cities represents a unique phenomenon, due to the programmatic nature of the designers' intentions and the variety of proposed solutions. Accompanied by a controversial debate, the cases here considered share the same principle of *critical reconstruction*. A principle which aims to correct the errors often carried out in a state of emergency in the post-war period and mostly based on alternative ideas of city. If this reaction – introduced by the revision of the principles of the Modern Movement since the 50s – arises from a slow awareness of the value of the historical heritage, it is with the first critical reconstruction of historical centres of the 80s that the will to recall concretely their identity is manifested.
The projects here presented are to be considered a mature phase of this reflection on urban history and the possibility to reactivate it nowadays. In the search of a new identity of their old characters, emerges a dialectic relationship between historical continuity, critical reconstruction and urban design, with recurring themes like: the memory of the layouts of streets and squares, the small-scaled parcels of the blocks, the reuse of historical typologies, the individuality of each house, the representativeness of the façade, the use of traditional forms and materials. According to a growing attention to the veracity of the original urban image, these projects are intended not as a mere *mise en scène*, but as a real implementation of the historical city with respect to current needs.

KEYWORDS

Germany; historical centers; critical reconstruction; urban image; identity.

INTRODUCTION

The ongoing rebirth of historical centers in some of the most significant German cities – Berlin, Dresden Frankfurt, Lübeck and Potsdam – represents a unique phenomenon, not only in Europe, due to the programmatic nature of its designers' intentions, the richness of the actors involved, the variety of proposed solutions. Accompanied by a lively and controversial debate, the cases here considered share the same principle of *critical reconstruction* (Caja 2018). Such a critical approach dates back to the revision of the urban principles advocated by the Modern Movement in the 20s of last century, which have built the theoretical basis for almost all the projects for the reconstruction of European cities, especially German cities, destroyed by the Second World War. This critical reflection on the fundaments of the historical city arose from the rediscovery of its temporal dimension, understood as a complex and stratified phenomenon built up over time. A phenomenon based on the overlapping of distinct historical layers, of different ideas of cities, surviving only in fragments and parts, for the analysis of which techniques similar to those of archaeological stratigraphy have been developed.

1. THEORETICAL BACKGROUND

The origin of this awareness dates back to the 1950s when, for the first time, the loss of the center and the need to restore a heart to the city became a main topic in the architectural debate (Rogers et al. 1952). The merit of this questioning was to highlight how the functionalist city, so attentive to the question of zoning and the optimization of living spaces, had completely forgotten not only the question of historical centers, but also that of newly founded *nuclei.* The question of the heart of the city was raised as a social, political and economic center as the issue of the new center for many of the devastated cities after the Second World War emerged. This concern for the regeneration of life in the city raised a great range of strategies on how to deal with it. However, many of these actions incorporated decontextualized parts attributable to the model of the open city, which caused the loss of historical identity of the urban space.

The urban analysis developed in Italy during the 1960s (Muratori 1960; Aymonino et al. 1970) became an operational tool to investigate the morphological structure and typological features of historical cities. If the merit of this intense analytical decade was that of classifying historical types and forms in a taxonomic way, its limit was that it didn't have a direct influence on the design phase, which was still understood as an autonomous moment in a tight continuity with the idea of open city based on abstract principles. The reflection of these studies on an international scale in the following decade rediscovered the value, the individuality and uniqueness of historical centers in their spatial and urban dimension. A rediscovery capable of activating a renewed attention towards them, no longer intended only as an object of study and analysis, but as real design references.

This gave rise later to an awareness of the need not only to revitalize these centers but, where necessary, to rebuild them according to the specific settlement principles of the European city (Delevoy 1978). From Léon Krier's first ideal projects for the reconstruction of German cities such as Bremen (Krier 1984) to the Internationale Bauausstellung Berlin (IBA 1984/87), the reconstructive principle took on a formal definition and critical emphasis, poised between revisionism and experimentation. The interventions carried out in Berlin in the two decades following the reunification of the city (1990), under the guidance of Hans Stimmann and a group of "architects of the city", constitute an updated example of this re-constructivist line, pursued today even in smaller historical centers, such as those analyzed here.

The projects here presented are to be considered as a mature phase of a reflection on urban history and the possibility to reactivate it nowadays. Aimed at reconstructing the identity of the historical features of the here considered German cities, they establish a dialectic relationship between historical continuity, reconstruction and urban design.

Within the history of reconstruction (Nerdinger 2010), these interventions prove to be paradigmatic for the questions they raise, but also for the concrete architectural solutions they offer, in their dialogic connection between copy and reinterpretation, which makes them true witnesses of the contemporary condition in which we live (Eco 2016). On the other hand, despite their obvious character of "constructed historical images" (Pehnt 2011), they are to be explained in opposition to the often exasperated desire to be current and new in much contemporary architecture.

In this sense, they constitute a new chapter in the reconstruction of historical centers, different from previous efforts, based on stylistic, typological or technical aspects, as it is shown in the well-known cases of post-war period such as Warsaw, Münster or Colmar; the Bolognese blocks (Cervellati et al. 1977); the Nikolaiviertel in Berlin with its use of prefabrication.

On the other hand, they are also different from the exported urban cities inside extra-European contexts, especially China (Bosker,

2013), for their different intentions and for the expectations they arise: no images to be evoked or suggested, but real pieces of the historical city to be reconstructed where they were before. There is no displacement, as in the idea of Satellite cities often proposed by the Modern Movement – see *Das Neue Frankfurt* by Ernst May – to be built outside the city center, but also in some Italian cases of urban reconstruction after natural disasters as in Gibellina, Teora or Monteruscello. But there is also no analogy, the typical compositional instrument introduced by Aldo Rossi in the 60s and then echoed in the European and American debate by authors like Colin Rowe, Miroslav Šik, Hans Kollhoff and others to recreate imaginary cities as collages of well-known architectures of the past. What these cases present is a new way of critical reconstruction *on site,* where the margins of interpretation emerge from the architectural solutions, more than from the historical morphological structure, which follows directly the original one, with its compact structure, the recognizability of its typologies, the representative character of its urban image.

2. DIFFERENT WAYS OF URBAN CORRECTIONS

These cases do not arise from an emergency condition or from the need to provide an immediate response, as in the above-mentioned experiences or more recent ones linked to natural disasters. The here presented projects are in fact cases of transformation and replacement of previous reconstructions and, as such, are rather to be considered as interventions of urban *correction* on earlier parts, realized after World War II, considered today, for various reasons, inadequate – for scale, morphological characters and architectural language – to the pre-existing structure of historical city. They are projects, therefore, that arise from the conception of the urban form as a palimpsest of different layers and historical traces, modifiable in themselves, and from the desire to restore, as far as possible, the image erased and lost over time.

2.1. Destruction vs. Reconstruction: Hildesheim as paradigm

A first paradigmatic case in this sense is represented by Hildesheim in Lower Saxony, where for the first time a post-war building was demolished to allow the reconstruction of the ancient historical ensemble of the medieval Marktplatz (Häger 2011). For the reconstruction of the most representative historical building on the square – the butchers' guild house (Knocherhaueramtshaus), built according to the typical wooden frame structure common to many other buildings of the historical *ensemble* –, a Hotel from the 1960s, in the typical forms of the post-war International Style, was demolished. (Fig. 1)

Figure 1. Hildesheim: Hotel Rose; Knochenhaueramtshaus, rebuilt (from: «Arch+», n. 204)

Likewise, in the other cases treated here, there have been similar cases of punctual replacement. At the Neumarkt in Dresden, it was necessary to remove an oversized *moloch* dating back to the 1980s, the extension of the Police Garrison, to allow the reintegration of the original perimeter of one of the eight historic blocks. At the Friedrichswerder in Berlin, the Foreign Ministry (Aussenministerium, 1964-67), built on Schinkelplatz site during the GDR regime, partly occupying the Bauakademie area and overlooking the Friedrichswerdersche Kirche both designed by Karl Friedrich Schinkel, was demolished. In Frankfurt, the Technisches Rathaus (1974), a brutalist building, was destroyed in 2010 to free the Dom-Römer Areal area, while in Potsdam the large complex of the Teachers' Training Institute on Friedrich-Ebert Strasse was recently removed to make room for the new blocks in the process of being built around the Castle. These out-of-scale functionalist buildings, dating back to the socialist or technocratic era, produced, for their volume and architecture, an alienating effect within the original historical fabric, without being able to regenerate a real urban life.
(Fig. 2)

2.2. The mixed Model: Leitbauten and Neubauten

Compared to Hildesheim, a true reconstruction *in style* (at least for the façades) of the original historical substance, the model adopted in the cases analyzed here is different and more articulated, as it includes both reconstructions *as they were where they were* and contemporary reinterpretations of the destroyed houses. The *mixed model* is based on the coexistence of *Leitbauten* and *Neubauten* – buildings reconstructed in the same way as the original ones and new buildings inspired by the existing ones.
This model was firstly adopted at the beginning of the new millennium in the reconstruction of the urban blocks around Dresden's Neumarkt, in conjunction with the completion of the reconstructed Frauenkirche.
Similarly, the Dom Römer Areal in Frankfurt consists of an *ensemble* of houses: about a third are copies of the originals and the rest are entrusted to a wide range of local and non-local architects. In contrast to the general plan for the reconstruction of the Altstadt, only a few blocks will be built in Berlin by

Figure 2. Demolished Buildings: Extension of the Police Garrison, Dresden; Foreign Ministry, Berlin; Technisches Rathaus, Frankfurt; Teachers' Training Institute, Potsdam.

a team of not only national studios, with a compact construction similar to the original, but without the stylistic restoration of the old houses.
The validity of the mixed model seems to be reconfirmed in the other two cases. The blocks around the Alter Markt in Potsdam are based on a general plan (Leitbautenkonzept), according to which different types of intervention are identified: from the faithful reconstruction of the original façades of 18th century buildings to new houses which follow the original volumetric and compositional guidelines.
Also in the case of the narrow and elongated blocks of the Gründungsviertel in Lübeck, a similar approach was followed under the guide of UNESCO: reconstructed pilot project buildings and current reinterpretations of the Gothic-merchant houses typical of Hanseatic cities.
In some cases, like Frankfurt, the dialectics between old and new is defined by the permanence of historical traces and *spolias,* considered as building stones to be reintegrated into the new houses. Their presence has the intent to make the reproduction of the original state – still alive in the collective memory of the actively involved community – more plausible.

2.3. Figurative reconstruction of Baroque city: Neumarkt, Dresden

As one of the most important squares in Dresden's historical center, the Neumarkt was built in the 16th century on the space of the pre-existing city walls in continuity with the market square (Jüdenhof). After the War destructions in 1945, its boundaries disappeared, leaving a large open space around the ruins of the Frauenkirche. During the clearing of their rubble, the complexes of the Johanneum and other historical buildings – still partially standing and available to reconstruction – were also removed.

The actual reconstruction of the urban blocks around the Frauenkirche – planned since the German reunification –, has profoundly transformed the place, according to the original baroque layout (SAK 2008) and its famous views painted by the Italian painter, Bernardo Bellotto. (Fig. 3)

Figure 3. Bernardo Bellotto, Neumarkt in Dresden, 1747 (Hermitage Collection)

The plan was based on the rebuilding of eight parceled blocks, including a series of historic pilot project buildings, under the coordination of the Gesellschaft Historischer Neumarkt Dresden (GHND). The reference points for the reconstruction were: the relationship with the perspective views of the paintings, the compactness of the building, the preservation of the original features, such as the road sections, the continuity of the façades, the eaves heights, the shape of the roofs, the layout of the plots, the type of court house. (Fig. 4)

Figure 4. Von Heinrich Lesch, Stadtplan Dresden, 1828 (extract); Neumarkt, 8 Quartiere, Plan

Figure 5. Neumarkt in Dresden, Quartier 1 and Frauenkirche, historical view and actual situation

The City Council, together with investors, has debated and supported these guidelines with the collective participation of the population, through referendums and public demonstrations. The guidelines set out in the Charter of Guidelines defined to rebuild more than 60 plots according to the principle of pilot project buildings and façades, while for the other plots, new houses with simplified façades were planned to fit harmoniously into the complex. The reconstruction of the historical blocks at the Neumarkt won the National Prize for Integrated Urban Development and Architectural Culture awarded by the Federal Ministry of Transport in 2009. (Fig. 5)

2.4. The reinvention of Renaissance city: Dom Römer Areal, Frankfurt

Accompanied by a broad and controversial critical debate, the recent inauguration of the new *old* town center, the Dom-Römer Areal, poses substantial questions about the future of European cities in the era of globalized standardization (Sturm et al. 2018). The project, which received the international MIPIM Award 2019 for the best urban regeneration plan, aims to give back an identity and a heart to the centre of Frankfurt, erased by the war and rebuilt in successive phases, without a precise idea of city. This intervention has filled the gap left by the demolition of the Technical Town Hall, a brutalist building from the 1970s. The old medieval parcellarium, the housing typologies with small courtyards and rich façades, dating back from Mediaeval to Renaissance time, were reused to restore the existing historical structure of urban spaces made of small squares and narrow streets. (Fig. 6)

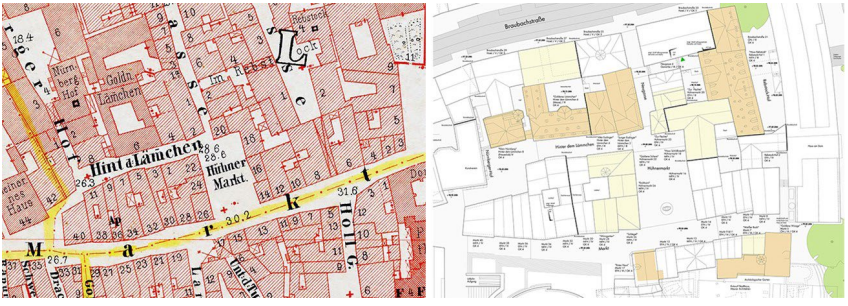

Figure 6. Frankfurt am Main, Ravenstein Plan, 1861 (extract); Dom Römer Areal, Plan.

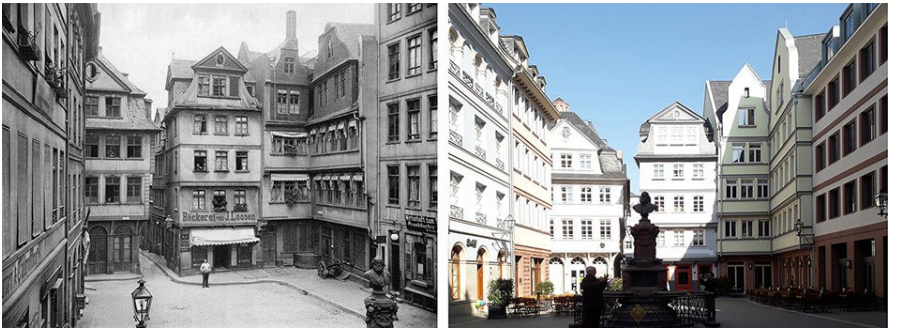

Figure 7. Dom Römer Areal, Hühnermarkt, historical (1904) and actual view.

The competition, promoted by the city, was carried out under the coordination of an architectural quality control committee chaired by local architect Christoph Mäckler. The plan, coordinated by DomRömer GmbH, which was set up specifically for the executive coordination and financing of the project, was based on the urban layout of the original medieval town center, restored while preserving the underground car park of the demolished building. Realized with the close participation of the citizens, the project saw the involvement of several local and some international architectural firms (56 in total), which, following a complex selective phase (5 to 8 different proposals were made for each plot), resulted in a very rich and multifaceted intervention, consisting of 35 houses.

The fundamental principle was based also here on two different degrees of reconstruction: on the one hand, the reconstruction *as it was and where it was* of the most significant historical buildings (Leitbauten) – initially eight, but which then became more – thanks also to the extensive documentation available, assumed as pilot project buildings. On the other hand, the construction of new houses, inspired by the old ones but not identical to them (Neubauten). (Fig. 7)

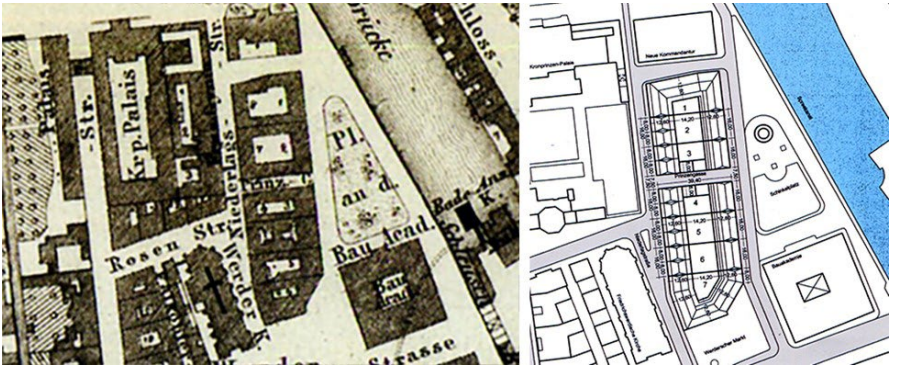

Figure 8. Friedrichswerder: W. Liebenow, Plan 1867 (extract); K.Th. Brenner, Plan 2005 (from: Stimmann 2014).

2.5. The difficult comparison with K.F. Schinkel: Friedrichswerder, Berlin

The area around the former Bauakademie, the Friedrichswerder church and the reborn Schinkelplatz (Fig. 8) – obtained after the destruction of the new Foreign Ministry of the GDR period – is part of the Plan for the city center (Planwerk Innenstadt) elaborated under the direction of former Senate Building Director Hans Stimmann (Stimmann 2014). The actual design of this new prestigious residential area follows the layout of the original blocks, on which the former house typology was to be reinterpreted according to its compact character and its high building density.
The difficulty of this intervention is revealed in the delicate relationship with the two adjacent brick masterpieces by Karl Friedrich Schinkel, the author of Berlin's classical rebirth at the beginning of XIX century, the church of Friedrichswerder and the Bauakademie, the first school of architecture which has been waiting to be rebuilt for more than ten years.
The block known as Kronprinzengärten on the west side of Friedrichswerdersche Kirche (plan: nps tchoban voss, 2014) appears as a simplified version of a first proposal, in which the individuality of each house was called into question by the presence of a common underground car park below the entire block. The unity of the intervention, guaranteed by the constant eaves height and the continuity of the street line, is however compromised by the heterogeneity of the façades, often characterized by strong historicist accents.
The block between the church and the Bauakademie is the result of the re-elaboration of a first plan designed by Klaus Theo Brenner in 2005, divided into two parts, with a total of seven independent plots, two of which are places at corners and five are extended from one side to the other of the block. During the realization this original parceled structure war replaced by a more compact one, with a smaller number of houses. (Fig. 9)

2.6. Reconstructing copies of copies: Alter Markt, Potsdam

The ongoing reconstruction of the urban blocks in the centre of Potsdam, around the Alter Markt, bordered by the Castle, the Nikolaikirche (both rebuilt in different periods) and the buildings along the river Havel, aims to restore the original settlement layout erased by historical events. And this, through the re-proposal of buildings that oscillate between stylistic reproduction and creative reinterpretation of formal principles taken from the past.

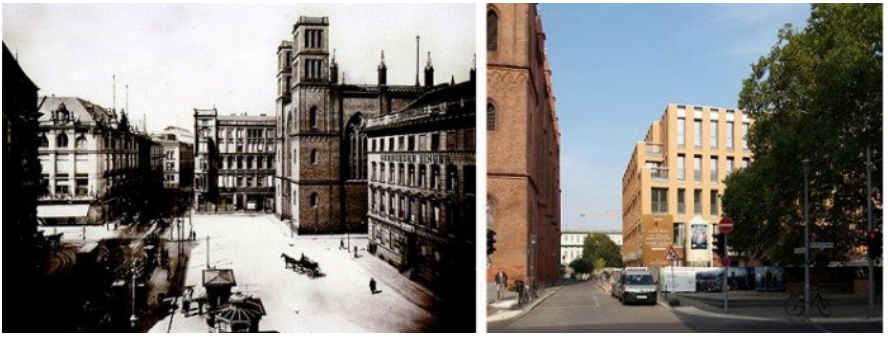

Figure 9. Werderscher Markt: Historical view (1904) and actual situation (House on the right by R. Moneo).

Although the first proposals date back to the last century, it was in 2004 that a competition was launched to redefine the area around the Alter Markt. The winning project introduced the idea of rebuilding the urban blocks around the Nikolaikirche and the Castle which was recently rebuilt almost *as it was and where it was* by architect Peter Kulka. This also gave rise to the idea of reconstructing the sequence of the old buildings on the waterfront, once called *Alte Fahrt* (STP 2012).
The plan of the pilot project buildings elaborated in 2012 (Integrierter Leitbautenkonzept Potsdam) proposed to rebuild the old blocks and, inside them, to reconstruct the houses according to the façades of the ancient models. On an urban scale, the *Leitbautenkonzept* also modified the wide street lane of the late 60s, diverting it and reducing its section, in order to make it possible to rebuild the Castle (even if shortened in length). The blocks under construction, following the demolition of the large building that contained the Fachhochschule Potsdam (FHP), were defined on the basis of a functional *mixitè* principle, capable of conferring new urban complexity and vitality on this central area of the city. (Fig. 10)
In the general plan of the blocks facing the Castle, the Nikolaikirche and the Alter Markt, a precise layout of the plots was outlined, such as to ensure the small scale of the individual houses adjacent to each other. The corner houses, often with façades referring to historical examples, were intended to hold together those arranged along the newly designed streets. Here, too, the levels of reconstruction range from reproducing *how it was and where it was*, in the case of buildings referred to pre-existing models, to a rebuilding subject to common urban and architectural constraints.
The first reconstructed buildings are those on the riverside (*Alte Fahrt*) in front of the castle: here the three adjacent palaces, Barberini, Chiericati and Pompeii, have already been completed, re-proposing the original façades. (Fig. 11)

2.7. The grammar of medieval blocks: Gründungsviertel, Lübeck

The Gründungsviertel (Founders' Quarter) in Lübeck is one of the oldest areas in the western part of the city. Despite some historical references, it underwent several transformations in the post-war period – the modification of some historical traces, the creation of a parking lot, the construction of two isolated professional schools – which led to a shift from the compact structure of the historical blocks towards a more thinned out one (https://www.luebeck.de).
Since the 1990s there had been plans for a restoration of the Gründungsviertel. With the support of the UNESCO World Programme

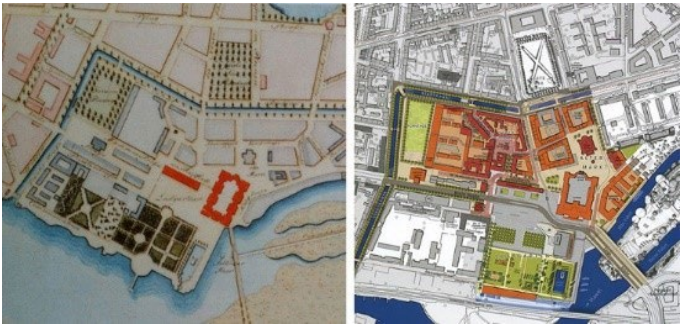

Figure 10. Potsdam: C.L. Oesfeld, Plan 1778 (extract, in red: the Castle); General Plan, 2012 (from: STP 2012).

Figure 11. Palazzo Barberini, Potsdam: 1907 (Photo: E. Eichgruen), 2019.

Lübecker Altstadt, the schools were demolished in 2009. Archaeological excavations and documentary analyses of the site were carried out on the cleared land.

The expected rebirth of the Gründungsviertel on the structure of the original parcels was thought of in the sense of a *critical reconstruction* of the historical layout of the city. The historical parceling of the land made available plots of different widths, thanks to which the richness and variety of the urban image of the past was recreated. In the project under realization, different typologies of houses can accommodate different destinations within a compact building line, which fits well into the minute scale of the medieval center of Lübeck.

Based on the "Rahmenplan Gründungsviertel", the conditions for urban reorganization and development of the district as a residential area within the city were defined in 2015. This plan forms the basis for a reorganization of the "founding district" according to historical street alignments, differentiation of the building type, variation of roof ridges and eave heights. (Fig. 12)

The reconstruction of the Gründungsviertel as an area of contemporary living is one of the most important and challenging projects in the Hanseatic city of Lübeck. The new district is based on the historical precedents, with its compactness of the blocks, the density of the plots, the building alignments, the pitched roof houses. In total, 170 units, including apartments, shops and offices on the ground floor, are foreseen.

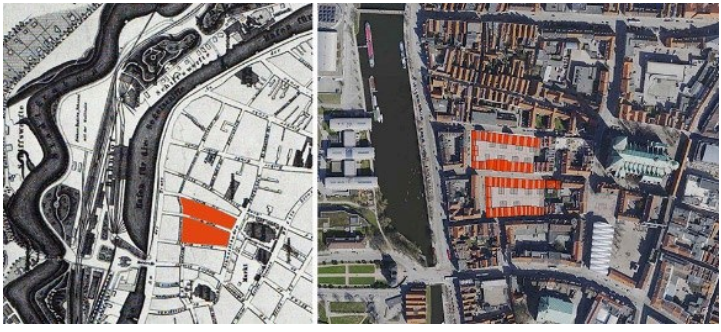

Figure 12. Lübeck, Gründungsviertel: historical situation (1872) and actual plan.

CONCLUSION

For the extent of the here analyzed interventions, recent critics have spoken of *reconstructionism* as a response to *deconstructivism* born in the late 1980s (Fischer 2011). With respect to the desire to dissect the historical city analytically – as if it was a patient on an operating table, attempting to dismember its individual pieces and subject them to conceptual processes of abstraction – the attempt here is rather to reintegrate the surviving fragments and traces still present within a unified image. The aim is to propose an updated version of the historical image that has been lost, following wrong – or today no longer suitable – choices. Choices mostly born from a desire to erase the historical and compact structure of the inherited city, often still legible in its foundations and building layout, and in any case received through the historical iconography, albeit in fragmentary form, in favor of new ideas of the city, which today have mostly proved to be inadequate.

Therefore, these cases are not to be understood as nostalgic attempts to reproduce the city *as it was,* nor as simple urban regeneration projects, but as advanced and mature examples of "critical reconstruction", according to the meaning introduced in the European debate since the 1970s. Projects that are also attentive to current issues related to sustainability and the return to a human scale of city living. In contrast to the futuristic ideologies advocated by the avant-gardes, mostly based on the myth of technological progress, these interventions start from the human scale as a measure to re-found the city and its architecture, in respect to actual needs of pedestrians, cyclists and new ecological means of transport.

In fact, these examples have already been taken as a reference by other non-European nations in search of their identity – following the too rapid processes of urban transformation in recent decades – through processes of reinvention of their history and tradition (Engel 2018). Abandoning the taboo of authenticity and historicity of the original, they reinvent traditional forms as if they were authentic. These "invented traditions" attempt "to establish continuity with a suitable historic past" (Hobsbawm 1983, p. 1).

Beyond the many doubts and criticisms that such interventions are raising, what is clear is that these are real projects of contemporary architecture, in which the historical city acts not only as an image, but as a concrete reference. It is still too early to assess whether their actual role within the city stops at the pure image, or becomes structural to the real life of those who live there. That is, if these reconstructed centers do not actually remain a simple tourist attraction, but become real places to live in, capable of truly reactivating the sense of community lost over time.

PAPER #3.16

ADAPTIVE REUSE & REGENERATION AS POTENTIAL FOR INDUSTRIAL SITES IN THE METROPOLITAN CITIES OF PAKISTAN

Naveed Iqbal[a], Koenraad Van Cleempoel[a]
[a]Faculty of Architecture and Arts, Hasselt University, Hasselt, Belgium

ABSTRACT

Karachi and Lahore are Pakistan's most important cities and they are also among the world's most densely populated cities. After the partition of the Indian subcontinent in 1947, there was a strong emphasis on textile, mechanical, and steel industries such as *Pakistan steel mill* in Karachi and *PECO industry* in Lahore. Like many other sites, there are still visible traces of its industrial heritage. Industries such as these were the reason for internal migration towards the cities providing jobs and life to the cities.

Currently, the urban infrastructure & public amenities of these cities are inadequate and insufficient. But more construction will lead to demolition generating a loss of important layers of recent history. The urban paradox, however, may create opportunities for the city to consider reusing its abandoned industrial sites. Such processes occur in Europe and are now also followed by China where the reuse of former industrial sites became levers for city development and regeneration. Chinese cities like Beijing and Shanghai have several recent examples of adaptive reuse of abandoned industrial sites.

The paper presents the analysis of Karachi's & Lahore's industrial legacy, its adaptive reuse potential, and aims for its regeneration through a local, socio-economic, and cultural revival. This project fits within a broader Ph.D. research on the industrial heritage of Pakistan; its identification and potentialities. Unlike Europe, Pakistan does not recognize industrial sites as heritage. Political instruments to offer new programs for these areas are limited and they are currently not on the radar as potential places for future city development. However, due to unprecedented demographic and geographic challenges, it may well become valuable to reconsider its potentials.

KEYWORDS

Industrial heritage; adaptive reuse; regeneration; revival; Pakistan.

INTRODUCTION

Pakistan's industrialization began during the British rule but continued after the Partition of British India in 1947. Shortly after the partition in the 1950s, it was the time of an apparent stagnation and mounting economic problems due to disruption of the separation. This was predicted by *TIME* magazine calling Pakistan an economic wreck (Zaidi 2005). By the mid 1960s, however, economic growth was strong and Pakistan was considered a model developing country (Papanek 2019). There were different policies in different regimes in the history of Pakistan which had a direct influence on the industrialization and de-industrialization of Pakistan (Table 1).

1947-58 was the first phase in which the foundation was laid for the coming years. The second phase was from 1958-68 with the continuation of the previous policies, at least in general direction and principles. During the second phase, the industries grew rapidly, and they were mainly developed by private entrepreneurs. S.Akbar Zaidi called it *The decade of development* in his book *"Issues in Pakistan's economy(2015)"*. The third significant phase was 1972-1977 and it was bad luck or bad management years in

TIME PERIOD	DEVELOPMENT / DOWNFALL
1947	Division of subcontinent industries after Partition
1947-1958	The first phase after partition, Civil bureaucracy, and industrialization
1958-1971	Civil and military-bureaucratic capitalism
1973-1977	Nationalization in Bhutto regime
1977-1988	Structural adjustment; the Zia regime
1988-2019	Crises and abandonment of Industries
Source: Based on *S. Akbar Zaidi's* book *Issues in Pakistan economy*	

Table 1. Pakistan Industrial development timeline.

Pakistan's industrial history. During this time the nationalization program was introduced in which some of the key private industries were taken over by the government and converted into state-owned industries like Batala engineering company BECO in Lahore was converted to Pakistan engineering company PECO. Most of the industries went into loss after nationalization and were shut down eventually (Zaidi 2005). Some of the abandoned industries are now engulfed by buildings around it due to the rapid urbanization of the cities.

The recent tide of industrial 'heritage' sites (Douet 2013; Wang and Nan 2007; 'The Nizhny Tagil Charter for the Industrial Heritage' 2003; Chen, Judd, and Hawken 2016; Xie 2015; Florentina-Cristina et al. 2014; Cizler, Pizzera, and Fischer 2015) and reuse is unique for south Asian countries. But it seems like an established and recognized strategy in city planning elsewhere. Many western cities preserved its industrial heritage and added values to it by inserting new programs with societal values. Pittsburgh, Chicago, and Detroit the major post-industrial cities in the United States have put life in the industrial spaces to becoming new community assets. Other examples of giving soul to abandoned industrial spaces include the navy yard in Philadelphia, or the High Line in New York (Robiglio 2017). There are also a variety of examples of activating industrial spaces in Europe like the LX factory in Lisbon Portugal, C-mine (former mining sites) in Genk Belgium, tobacco company converted into residential use Wills buildings Liverpool, Richmond station in north Yorkshire converted into restaurant cinema and many more ('Re-Using Industrial Sites | Historic England' n.d.; 'Lx Factory' n.d.).

When it comes to the Pakistani context, little to no research and practices have been done related to industrial heritage identification and reuse. Pakistan Industries constructed after the partition are not old enough to be considered as heritage according to the Pakistan antiquity act 1975 (last modification in 1992) ('Antiquities Act1975' 1992). Besides numerous industrial sites like abandoned tobacco factories, food factories, steel mills, textile mills, warehouses, salt mines, and railway buildings, industrial heritage, and its potential is little recognized in Pakistan. There are no policies and guidelines at hand related to industrial heritage conservation, regeneration, and reuse. The argument of this paper, therefore, is that the industrial heritage sites of Karachi & Lahore have the potential for adaptation and can be initiated by regional-level factors. We want to identify 19th and 20th-century industrial buildings and the involvement of cultural capital (i.e. local artist community, cultural organizations, educational institutes; and the introduction of industrial heritage in regional cultural and heritage policy).

Since the topic of industrial heritage is a new concept for the Pakistan Heritage field, so the first part of the paper is case selection. The case selection area is done broadly by selecting the two largest cities of Pakistan briefly explaining its history and its potential in the field of industrial heritage and its adaptive reuse. The second part is an analytical framework discussing physical type of industrial heritage in Pakistan, possibility in its regeneration, and interventions for activating such sites. The last part discusses international case studies of industrial heritage and its reuse, selected in a way which are relatable to the industrial sites in Pakistan and its potential in the locality in terms of issues and possibilities.

1. CASE SELECTION

The cities of Karachi and Lahore are selected as a starting point for the study and identification of industrial heritage in Pakistan. Both cities have metropolitan characteristics. Karachi is the capital of Sindh province (also the first capital of Pakistan) and at the same time economic capital of Pakistan. It is also the largest city of Pakistan in terms of population (Table 2). The commercial functions of the city are strengthened by international investment, due to its maritime business (Khuhro and Mooraj 1997). Similarly, Lahore is the capital of Punjab province and the cultural capital of Pakistan. Lahore is the second-largest city in terms of population in Pakistan with a history dating back to 1000BC (Kabir, Abbas, and Hayat 2017) (Table 2)(Fig 1). Both cities have large stocks of industrial heritage but from different activities like steel, engineering, textile, and food industries. Unfortunately, most of the practices related to the industrial buildings after closure is neglect or demolition. Unlike the situation in Europe or the USA, such sites are not considered as heritage, witnessing from a particular kind of urban memory. They are measured with the same parameters and rules with which cultural and religious heritage are measured. Although according to *Nizhny Tagil* charter ('The Nizhny Tagil Charter for the Industrial Heritage' 2003)industrial heritage is defined differently;

> Industrial heritage consists of the remains of industrial culture which are of historical, technological, social, architectural or scientific value. These remains consist of buildings and machinery, workshops, mills and factories, mines and sites for processing and refining, warehouses and stores, places where energy is generated, transmitted and used, transport and all its infrastructure, as well as places used for social activities related to industry such as housing, religious worship or education. The historical period of principal interest extends forward from the beginning of the Industrial Revolution in the second half of the eighteenth century up to and including the present day, while also examining its earlier pre-industrial and proto-industrial roots ('The Nizhny Tagil Charter for the Industrial Heritage' 2003).

City name	City orientation	Population	Area	Types of industries
Karachi	Economic capital, beta global city, cosmopolitan, trading port since 1852	14.2 million	3780 sq.km	Textile, state-led heavy Industries: Steel Industries, transportation, footwears
Lahore	Cultural capital, Historically rich, Educational institutes	11.2 million	1305 sq.km	State-led heavy industries: Automotive & Agriculture machinery, Electrical equipment, small Industries

Source: Based on National Bureau of Statistic Pakistan (2017)

Table 2. Statistics and types of industries in Karachi and Lahore.

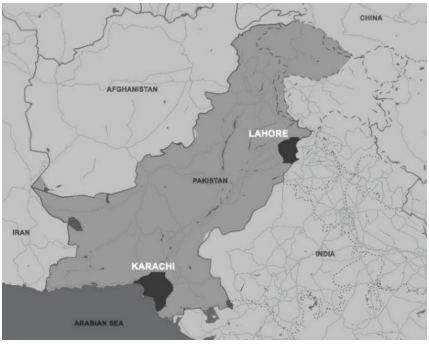

Figure 1. Source: Google Maps, www.google.be/maps edited by author

Instead of demolition the urban paradox mentioned earlier could be the reuse of these sites for a new purpose. Adaptive reuse – the addition of new programs to an existing historical building (Plevoets and Cleempoel 2011) – is the richer option compared to demolition. Rebuilding also enhances the long term usefulness of a building (Bullen 2007). Conversion of architectural sites is not a new phenomenon in the history of the discipline (Wilkinson et al. 2014). Chen, Judd, and Hawken (2016) refer to Grodach and Loukaitou (2007) to develop three cultural development strategies: "progressive strategies", "creative class strategies" and "entrepreneurial strategies" and used it to investigate the adaptive reuse of industrial heritage for cultural purpose in Beijing, Shanghai and Chongqing (Table 3)

Pakistan's industrial development timeline is almost the same as in China. Modern industrial development in China after the 1840 Opium war with Britain was continued after founding of the People Republic of China (PRC) in 1949. In the 1970s due to the high level of urbanization and pollution in the city centers the industries were shifted and the old industrial sites were regenerated and adaptively reused as cultural precincts (Chen, Judd, and Hawken 2016). Most often, adaptive reuse is considered as the only option for regeneration of an industrial building or area. This roots of adaptive reuse in the United States can be found in the 1960s in economically buoyant cities like San Francisco and Boston. Architects Wurster Bernadi and Emmons conversion of Ghirardelli chocolate factory to offices, shops, galleries, and restaurants in the 1964 & 1968 set a style that has followed and evolved worldwide (Douet 2013). The trend of waterfront rehabilitation based on recycled historic buildings have turned industrial waterfronts into desirable properties like St Kathrine Docks, London; Albert Dock,

Strategy type	Goals	Types of cultural projects and programs	Target audiences
Progressive	Community development Arts education and access	Public arts centers Art education and Programmes	Underserved residential population
Creative class	Economic growth through quality of life amenities Promotion of "creative economy"	Arts and entertainment districts Collaboration between arts and private sector	Prospective residents "Knowledge-based" workers
Entrepreneurial	Economic growth through tourism and city image Private sector investments	Cultural landmarks Cultural festivals Promotional activities	Tourists Affluent residents

Source: Based on (Grodach and Loukaitou-Sideris 2007) table by (Chen, Judd, and Hawken 2016)

Table 3. Types of cultural development strategies.

Liverpool; Darling Harbor, Sydney and Granville island, Vancouver. The conversion of the great textile mill complex of Lowell, Massachusetts, into a National historic park is also an equally influential project. (Douet 2013).

The mentioned cities in Pakistan are famous for their historical importance, art, and architecture. National Academy of Performing Arts (NAPA) is one of the famous schools of performing arts in Karachi. National College of Arts (NCA) Lahore is one of the top architecture and art schools in Pakistan. The abandoned industrial sites can be used by these artists communities if assisted by the government and can be a starting point for its regeneration. The second important issue in these cities is the shortage of public and green spaces. According to a report in Dawn newspaper, green areas in Karachi decreased by 4 percent from 2005 to 2017. Many residential neighborhood have almost no green areas,(Ahmed 2020). According to the united Nations health standards, the availability of green space is at least 9 sqm per person while most areas in Lahore city fall short than the UN standards (Shirazi, Zia, and Minallah 2014). The industrial sites have also the potential to be reused as public green spaces and community centers. The examples of industrial sites in Pakistan are discussed below in section four.

2. POTENTIAL INTERVENING FACTORS; AN ANALYTICAL FRAMEWORK

This section characterizes the local intervening factors which can be a lever to developing and reusing industrial heritage or sites. Most of the industrial heritage of Pakistan can be identified from 1958-1971 during the civil and military bureaucratic capitalism and then from 1977-1988 after structural adjustment policies by Zia Regime.

2.1. Physical type of industrial heritage

After the partition, larger parts of the industries of Indian subcontinent came in the territory of India, most of the industrial development in Pakistan started in the mid-20th century (Jaleel 2012). Current industrial types in Pakistan were brought up in two periods, first phase after the partition in the 1950s civil bureaucracy and industrialization and in the 1970s civil and military bureaucratic capitalism. The third period after the 1970s stopped most of the industries due to various reasons one of which was the Nationalization policy.

2.2. Possible role of the community in regeneration

In various examples in the UK, USA, Europe, and now also in China, we see that bottom-up initiatives from the cultural community started using the abandoned industrial sites due to laxer controls and lower rates and converted them into art districts (Evans 2009). In the informal cultural district formation, the local artist community plays a leading role. The organic development of creative clusters and cultural quarters emerged in the USA and Europe in the 1970s and 1980s (Zielke and Waibel 2014).

2.3. Policy intervention influence on activating such sites

The main stakeholders and the different development modes for the governance of developing creative spaces in china are summarized by Zielke and Waibel (2013). The main stakeholders in the development of cultural precincts from redundant industrial sites include the local state, artist community, privates developers, and the actual owners (Chen, Judd, and Hawken 2016). Four types of development methods are put forwarded for the development of creative spaces. *Bottom-Up method*; the method in which industrial

areas are organically occupied by artists and then through official policy promoted by the local government. *Top-Down*; the method in which the local government plays different roles to arrange a common ground for investors owners and developers. *Public-Private Partnership PPP*; In this method the private investor and local government team up to establish a public-private company to coordinate interest between them. *Private Development*; In the private development method the government acts as a supervisor or supporter while the private developer finances most of the investment and in return gain the value addition of the property. In all the development modes local government is involved in one or another way.

3. THE INDUSTRIAL HERITAGE REUSE IN INTERNATIONAL CITIES AND POTENTIAL IN THE STUDY CITIES: A CASE COMPARISON

Besides a handful of immediate reuse potential industrial heritage sites in the cities of Lahore and Karachi (Table 4), they are still standing abandoned and are on the verge of decay, in some cases demolition. First, the urgency is to consider such sites a valuable heritage asset as mentioned by James Douet.

> The industrial landscape is a misunderstood heritage, at worst urban rustbelt, dangerous, a toxic wilderness; at best, an outstanding historical resource to be re-used, regenerating communities, offering real richness and opportunity, reinforcing cultural identity and creating new commercial prospects. But it can also be a vivid reminder of how today's world came to be the way it is, when industry employed whole communities and provided the heartbeat for many towns and cities. In this respect these historic industrial landscapes deserve our closest attention (Douet 2013).

The antiquities' acts and policies related to the heritage of Pakistan (M.R Mughal 1995) is focused on the archeological artifacts, cultural and religious heritage. Industrial buildings in general are not considered as heritage and neither the reuse potential is exploited. Comparing Industrial heritage reuse trend in the city of Beijing summarized by Chen, Judd & Hawke in three ways; In the 1990s it was spontaneously reused by the artist community; in the 2000s was established by private developers through PPP and was driven by the local government in 2010. An example worth mentioning is the conversion of a formal electronics factory

City name	Redundant industrial buildings	City rundown
Karachi	Textile industries, Steel Industries, transportation, railway infrastructure, seaport related infrastructure	Economic capital, artist community, Educational institutes, Entrepreneurs, Small businesses, Fashion capital
Lahore	Mechanical industries, leather industries, textile industries, flour mills	Artist community, Cultural capital, Historically rich, Educational institutes

Table 4. Abandoned industries and potential reuse users.

from the 1950s to "798 Art Zone" in the 1990s. Promoted by the Beijing government it was converted into a "mature creative cluster" from an "underground space of art" (Zielke and Waibel 2014)(Fig 2-3). Chunming Slub Mill a defunct cotton factory in Shanghai is similarly converted into an art district, it was first reused by local artists in the 1990s and then expanded by the Shanghai CIC policy in 2004 (Chen, Judd, and Hawken 2016)(Fig 4).

3.1. Industrial development history of Pakistan

The industrial legacy of Pakistan can be traced back to the mid-19th century during the British rule in the subcontinent. But after the partition in 1947 Pakistan got 34 industries out of the total 955 in the Indian subcontinent. Most of them were small size industries and were based on raw materials like small sugar mills, cotton ginning factories, flour mills, etc. The first investment in the industries was by the private investors from 1947-1950. In 1952 Pakistan Industrial Corporation PIDC was established by the government of Pakistan to invest in heavy industries like cement, fertilizer, jute mills SUI Karachi gas pipeline and by 1971 completed 59 industries and created a solid industrial sector base for Pakistan. The GDP share of the industrial sector rose from 9.7% in 1954-55 to 11.9% in 1959-60. After the 1960s Pakistan started investment in heavy industries shifting from consumer goods industries such as mechanical, Petro-chemical, iron, and steel. From 1971-77 the industrial growth and export were disappointing due to various reasons like; separation of East Pakistan, the Indo-Pak war in 1971, suspension of foreign aid, loss of local market of east Pakistan, fall in export, nationalization of industries, and unfavorable investment climate (Jaleel 2012). Due to the above-mentioned reason, there were a lot of industrial buildings abandoned which can be reused for different functions by suitable interventions.

3.2. Cultural capital artist community, cultural organization and Industrial heritage in the study cities

If you take a comparable example of a city to Lahore in terms of industrial development and its reuse will be Beijing. The industrial heritage reuse was driven by the critical mass of artists as Beijing is rich in history due to serving as a capital for five dynasties. Beijing has long been a political and cultural center (Chen, Judd, and Hawken 2016). Similar is the case with Lahore, it is the cultural capital of Pakistan and its importance can be seen in the history of different Rules like Hindu raj, Afghans, Mughals, Sikhs, Britishers, and many more (Baqir 1985). Due to its geographic location, Lahore once called the Paris of the east is still the center of attraction for many in recent years (Kabir, Abbas, and Hayat 2017). Lahore has many universities, art schools, theater, and libraries with a huge density of artist community as compared to other cities of Pakistan (Table 5). Some of the leading art schools in the country are in Lahore. Considering the presence of such a potential artist community there is an opportunity in the industrial sites like PECO industry in Lahore to be reused as cultural precincts like M50 in Shanghai and 798 Art Zone in Beijing. Pakistan Engineering Company PECO which was once Batala Engineering Company BECO established in 1932 by Chaudry Muhammad Latif Batala was one of the leading and Key industries of Pakistan before the nationalization policy (Khan 2008). After the nationalization policy, it went under loss and was eventually closed, currently, it is lying abandoned in the center of Lahore within a densely populated area (Fig 5-6)

City name	Listed universities	Art schools	Museums, Libraries, cinemas & theaters
Karachi	26	18	68
Lahore	34	16	52

Table 5. Educational institutes and cultural resources in the study cities.

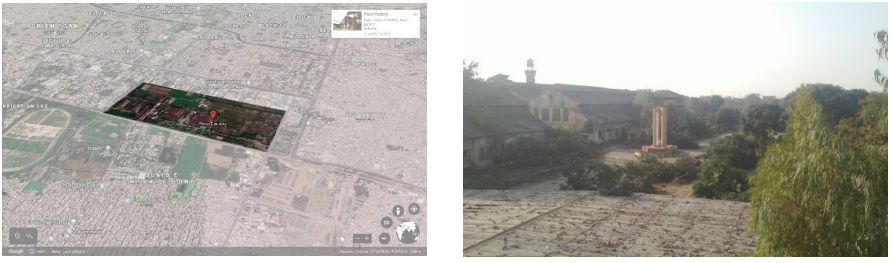

Figure 5-6. PECO industry Lahore Pakistan: (Google earth) edited by the first author

The PECO industry lies almost in the center of densely populated Lahore with universities and sports areas in the immediate vicinity. These points add in the value and promising reuse of such a potential site in the center of the city if opened and assisted by the local government as it is walled and guarded in the current situation.

Similarly, if we talk about the city of Karachi a comparable example is Shanghai. During the trading port period, Shanghai was developed under the influence of semi-colonial and semi-feudal system and the modern culture known as sea culture has a hybrid nature and fusion of western and eastern culture (Wu 2004). Its culture is more market-driven and is based on design industries like media, fashion, and advertising (Ren and Sun 2012). Similarly, the case with Karachi as it is the fashion capital of Pakistan with an active seaport and its architecture is mainly influenced by British colonial architecture. Karachi has also a vast market of small industries and handicrafts. Karachi also has many universities, art schools, libraries, and museums with one of the active artist community of Pakistan. There are several examples of abandoned seaport sheds, railway infrastructure textile industries which can be reused for a new function in the densely populated city of Karachi. The most important example is the recently abandoned Pakistan steel mill PSM with an area of almost 76 square kilometers constructed in the 1960-70s with the help of the USSR. 20 different plants including a thermal power station, forklifts, warehouses, conveyor belts, railway tracks, stockyards, and dozens of other industries standing still (Hasnain 2016) (Fig 7-8). Although political figures of Pakistan always discuss about reviving the PSM but it is already consider as sick industry by some of the economist as it is under the debt of almost 130 million USD.

Figure 7. Pakistan Steel Mill Karachi: (Google maps) edited by first author

Figure 8. Pakistan Steel Mill Karachi: (pakistantoady.com)

3.3. Policy intervention

Whether it be a top-down, bottom-up, public-private partnership PPP or private development the local government involvement in reusing such kind of industrial sites cannot be ignored. More specifically the strategies for the promotion and development of creative industries on such abandoned industrial sites like providing funding, sponsoring cultural spaces, and providing a resident card for prominent professionals (Chou 2012). Such initiatives have been given in the abandoned industrial sites of Beijing which acted as a catalyzer for creating a full-fledged cultural district. Capital steel industrial Park in Beijing is an example of such state-sponsored cultural projects.

DISCUSSION AND CONCLUSION

Industrial development history has left Karachi and Lahore with a substantial amount of industrial heritage. But they are not considered as heritage, which, sadly, seems to hinder their development. We observe the same industrial development timeline in the cities of Beijing and Shanghai, but also in other European or American cities. The first step towards the preservation of industrial heritage in Pakistan is the identification of its potential. Besides looking at it from a Heritage perspective it also creates the possibility for reuse and can be a key area in the city regeneration. For example, the PECO industry in Lahore can be a vital organ for the city's cultural and art activities. Similarly, the Pakistan steel mill can be a center for shifting the urban nucleus of the city as it is already saturated. The heritage reuse policy requires greater consideration of the regional context. Both the cities face a shortage of green urban spaces and parks and these abandoned sites have the potential to be reused as green public and community spaces.

The findings of the paper are; the major intervening factors in starting for a chain reaction of industrial heritage reuse in Pakistan can be government policy and cultural capital. Government policies can start from; sponsored events flagships, incentive policy on a local cultural program, funding on cultural festivals in such kind of abandoned sites. Investigating the regional context and involving the local cultural capital like public cultural organization, public or private cultural enterprises, educational resources; schools, universities, colleges, artist community, and professionals involved in cultural industry. Involving the mentioned resources of the city and providing incentives can be the start of developing and regenerating such abandoned industrial sites which is a sustainable way of preserving such sites both in a material and environmental point of view.

PAPER #3.17

METAMORPHOSES IN PARIS: THE FATE OF SAMARITAINE AMONG PRESERVATION AND INNOVATION

Antonella Versaci[a], Alessio Cardaci[b]
[a]University of Enna 'Kore', Faculty of Engineering and Architecture, Enna, Italy
[b]University of Bergamo, Dept. of Engineering and Applied Sciences, Bergamo, Italy

ABSTRACT

In our times, cities regenerate by not only welcoming new and unprecedented activities but also reorganizing themselves from the morphological and social points of view. For a long time, the historic centre has wrongfully been considered as a space crystallized over time - implemented through integral conservation - that has transformed the urban fabric into an enormous museum that is not coherent and no longer meets the needs of the contemporaneity. Today, finding a dialogue, however difficult, between tradition and innovation is essential to implement renewal actions that inevitably must and must increasingly involve the built heritage. A complex palimpsest in which traces of the history and life of man are imprinted and deserve to be read and respected within inescapable mutative processes. However, these processes should be implemented without violence or cancellation, in a planning vision, not limited to the achievement of economic well-being but also to the reinforcement of the cultural dimension of development. Focusing on the transformations that involve the very heart of Paris and, in particular, an iconic place of commerce such as *La Samaritaine*, this essay aims to analyze the complexity of planning strategies in which specific actions of restoration, renewal and reuse involve the entire city to reconfigure new images and urban spaces.

KEYWORDS

Urban transformation; commerce; cultural heritage; architectural design; Paris.

INTRODUCTION

The concept of 'innovative' city refers to an archetype of technologically advanced and particularly characterized urban space. However, towns to regenerate need not only to welcome innovative activities but also to reorganize themselves from a morphological and social point of view.
For a long time, the idea of the historic centre has wrongly given back an image of space crystallized over time - implemented through integral conservation - which has transformed the urban area into a huge museum that no longer fits the demands of the contemporaneity. Today, having overcome this concept, to find a dialogue, however difficult, between tradition and innovation is indispensable given the implementation of renewal activities that inevitably will increasingly involve the built (Purini 2008). A complex palimpsest where the traces of human history and life are imprinted, which deserves to be read and respected within inevitable changes. Metamorphoses that should, however, be implemented without violence or cancellation, following a strategic vision, not limited to the achievement of economic well-being but also aimed at strengthening the cultural dimension of development.
In this sense, emblematic is the city of Paris. Its evolution is, in fact, the result of a continuous

process of adaptation and transformation - obviously not free from contradictions - regulated by debates, challenges, negotiations and crossed by a contextual and progressive change in the conceptions and forms of planning. The latter was first understood as a general instrument and then as a strategic tool, based on long-term choices and applied through timely interventions.

If a radical urban reorganization commissioned by Napoleon III and the prefect Georges Eugène Haussmann was carried out between 1852 and 1870, it was from the second half of the 20th century that the greatest and most traumatic changes occurred (Fumagalli 2008). In the thirty years that followed the end of the Second World War - the so-called *Trente Glorieuses* - French territories were affected by countless operations centred on the merciless operating practice of *the rénovation urbaine*. A concept with a vague and unclear meaning that was essentially translated into modernization - or demolition/ replacement - operations. Especially in Paris, it was materialized in a series of exemplary initiatives aimed at 'revisiting' the city. Although already in 1962, the Malraux law introduced provisions concerning the safeguarding of historic centres, the first decade of application of this instrument - innovative and courageous but extremely rigid and problematic - was still essentially based on the praxis of renewal (Versaci, 2012). This led to the erection of towers, slats and other rationalist buildings in the core of the cities (Nigrelli 1999).

However, new concerns regarding the conservation and recovery of the existing urban and building heritage gradually emerge. By showing all its limitations and contradictions, the practice of renewal, therefore, opens the door to the formulation of new urban theories more attentive to the quality of the city and the life of its inhabitants. With the election to the presidency of the Republic of Valéry Giscard d'Estaing, the thinking of the institutions on the urban transformations hitherto accomplished changes. The excesses of a certain 'quantitative urbanism' are criticized, also thanks to some vehement debates conducted by intellectuals and to a population more sensitive to the fate of their towns (Pinon 2011).

In 1977, the appointment of Jacques Chirac as the mayor of Paris, initiates a substantial review of the ongoing renovation operations, thus helping to define the guidelines of a new French urban planning more prone to the requalification of built heritage and conceived to both respond to the deep aspirations of the community and foster social relations. In 1978, the *Paris Projet* magazine focuses on the description of the objectives of this new policy. This latter proposes a return to volumes coherent with the peculiarities of the context, greater respect for the urban fabric, the protection and improvement of some elements of the existing habitat, the maintenance of traditional craft and industrial activities, the development of gardens and public spaces. In these years, France thus discovers the 'urban form', long denied by a technical approach to development.

An attempt will, thus, be made to achieve the 'active' preservation of the architectural and urban heritage of Paris - carried out through new constructions in the historic centre and its main sites (APUR 1985) - however not free from demolition activities and as many disputes.

Architectural heritage protection that in Paris takes on the forms of the urban project and which is expressed as a series of important operations, such as the remake of the old central food market *Les Halles* that opens in 1979, while devoted to other commercial function. A 'serious' mistake that Paris will never forget without ever stopping 'reinventing' itself, often at the expense of the Paris skyline[1]:

[1] The offence deriving from the suppression of the Baltard pavilions, a now universally recognized masterpiece of industrial archaeology, or the quality of the architectural organisms then made in replacement, globally devoid of character, banal, often ugly, will never be forgiven. at least according to contemporary perception. Above all, architecture is a clear expression of an ephemeral and technologically constantly evolving world, which has inevitably collided without ever reconcile with the values of permanence and immutability of the historical context.

> Paris is a fragile beauty. No city has captivated the imagination or inspired like Paris. It is a beauty different from any other city in the world. And the skyline is integral to that beauty. Like a subtle membrane containing the city in its most delicate aspects, this skyline defines the city. Destroy this, and you destroy Paris. The city will go on standing, and people will come, of course, but the city will be diminished (Pitt 2016, 119).

Today's Paris presents a succession of modern additions that help to define its image of charm, well-known and appreciated all over the world. Works of architecture, which nevertheless at the time of their creation created doubts and malaise: from Beaubourg (1977) to the Grande Arche in the La Défense district (1989) via the Arab World Institute (1987) and the Pei's Pyramid at the Louvre (1988).
Still, in the last decade, numerous experiences of transformation of the urban space have been planned in the French metropolis. Many of them are summarized in iconic projects - often huge skyscrapers - unfortunately inevitably associated with the negative image of a liberal and globalized economy that seems to contradict sustainable and lasting choices regarding plans, materials and construction techniques used (Mercuriali 2018). From the project for the new Forum des Halles (2018) to the various modernization and conversion programs of the Gare du Nord and the Maine-Montparnasse district currently underway, up to the project concerning the Samaritaine, numerous are the demolition/reconstruction actions and extensive changes that affect the commercial sector. They call for some reflections on the scope and quality of these interventions.
In particular, the case of the La Samaritaine - a historical department store among the most representative of early 20th-century architecture and dear to Parisians because it conveys to them, in a contemporary context, the spirit of the *Belle Époque* - is of great interest. The complex has for some years been affected by a vast campaign of works aimed at its renovation. A bold operation that has sparked numerous controversies and that deserves further study, especially for an overall evaluation of the activities that include new grafts in the existing fabric.

1. THE SAMARITAINE AS THE ARCHETYPE OF TRANSFORMATION

The witness of a historical period marked by significant changes impressed, first of all, by the industrial revolution, the department stores appear in the Parisian landscape, along the course of the second half of the 19th century. The great success of Universal exhibitions[2], the new policies of centralization of the railway sector and, within the cities of Paris, the spread of horse-drawn omnibuses that transport a large clientele in the centre, favour an ever-greater development. The introduction of new sales methods (free admission, fixed prices, a wide range of goods) and, at the same time, the possibility of growing - also in a colossal way on the internal courtyards, where it is possible, thanks to the use of the iron and glass, providing lighting through the establishment of zenithal windows - are elements that will facilitate their quick expansion.
In the new Parisian districts resulting from Baron Haussmann's *Grands travaux* and, in particular, in the transit and high-traffic areas, firms are confronted to find strategic planting opportunities. New imposing buildings replace old ones - picturesque but unhealthy - that persist in the heart of the city: the department store is a "modern, solid and light cathedral of commerce, created for a people of customers" - as Émile Zola claimed (Zola

[2] After those of 1855, 1867, 1878, 1889, that of 1900 was the triumph of iron architecture and Art nouveau.

1883, 282) - intended to revolutionize retail and city lifestyles (Leveau 2006).
Five department stores overlook the Parisian market during this period, transforming its landscape: Le Petit Saint-Thomas and Au Bon Marché[3], the oldest *grand magasin* created in 1852 in rue de Sèvres (7th arrondissement), Les Grands Magasins du Louvre[4], in rue de Rivoli, built in 1855 and definitively closed in 1974, the Bazar de l'Hôtel de Ville (known as BHV)[5] opened to the public in 1856 at No. 52 of the rue de Rivoli right in front of the town hall, the Printemps Haussmann built in 1865 in the Opéra district, at No. 64 of boulevard Haussmann, La Samaritaine founded in 1869 facing the Seine, near Pont Neuf and, finally, Les Galeries Lafayette opened in 1894 in the Opéra district, at No. 40 of boulevard Haussmann (Fig. 1).
For these private companies, the role played by architectural design in the conquest of customers is very important (Vayron 2015). The architects in charge of their realization define a style that becomes specific to the department stores, characterized by spectacular codes inherited from the great noble palaces: a classic style chosen to impress passers-by and elevate buildings to contemporary monuments. Extremely attractive features distinguish the façades, the layout and ornamentation of the roofs, the height of the buildings often established in derogation of municipal regulations (Cantelli, 1991). They also concern the interiors, which are sumptuous, true and own triumphs of frescoes, iron's florilegia and stained-glass windows, to adequately serve the flourishing bourgeoisie of both the Second Empire and the Third Republic. In the context of this Parisian transfiguration, the case of the Samaritaine is representative, also for the more recent evolutions that make it one of the most interesting cases of contemporary transformation.

1.1. La Samaritaine, a monument of Modernism

The history of the department store is linked to the lives of Ernest Cognacq - a self-

Figure 1. Construction phases of La Samaritaine. Source: (La Samaritaine, 2015)

[3] In 1989, the name changed to the current Le Bon Marché.
[4] Today on the same site is the Louvre des Antiquaires.
[5] Since 2013, renamed Le BHV Marais.

made man - and his wife Marie-Louise Jay, a first salesperson at Bon Marché). This extraordinary entrepreneurial activity started, in 1870, in a commercial space of just 48 square meters located on the corner of rue du Pont Neuf and rue de la Monnaie, in the Parisian 1st arrondissement. Their small boutique was called La Samaritaine after the old 17th bas-relief representing Jesus with the Samaritan woman placed on the nearby Seine water pumping station. The shop, thanks to the low price policy and the choice of goods suitable for multiple customer groups - but above all because it allowed small producers to have a space to sell their items directly - soon began to grow by acquiring the nearby shops, remodelling at the same time the whole district. The success of this epic commercial adventure is due to the visionary and utopian spirit of its owners and at the same time "to the conscious effort of some French architects towards new forms and towards adapting architecture to the needs of modern life" (Cognat 1930, 1). First of all, the Belgian Frantz Jourdain, a proponent of Viollet-le-Duc structural rationalism, a trenchant critic of the *École des Beaux-Arts*, and ardent supporter of Modernism. He was hired in 1883, later helped, and gradually replaced by the pupil Henri Sauvage, a renowned protagonist of *Art nouveau* and later of *Art déco*. Jourdain and Sauvage together will dare systematise the use of iron and glass to build quickly without ever stopping the sale:

> Tempting facades, dizzying halls, exuberant and offbeat advertisements ... sometimes at the risk of shocking good taste, nothing is daring enough to seduce a clientele that attracts the decor, the profusion of goods and affordable prices (Cabestan 2015, 5).

From the first nucleus, *Magasin* No. 1 extends along the whole lot. To establish a constant relationship between artistic production and daily life is the goal that governs Jourdain's activity for the Samaritaine. Following the thought of the philosopher Hippolyte Taine, he believes that works of art are the reflection of the social moment and civilization (Barré-Despond 1988). He is sure that the artist has a leading role in modern life - "talent has always adorned with magnificence or grace the flattest, brutal requirements of existence" (Jourdain 1909) - and then entrusts in 1891 to the painter and decorator Charles Toché, the realization of a fresco on the façade on what will become the *Magasin* No. 2. Jourdain is then called to unify the neighbouring buildings acquired over time through a series of important internal structural modifications and some specific modifications on the external fronts.

Works of the *Magasin* No. 2 in rue de la Monnaie, in front of the first shop, essentially take place in two phases (1904-1910 and 1927-1929) and are marked by internal and external transformation, expansion campaigns, and later by bold reconstructions. A metal and glass architecture - technologically performing and long-lasting - gradually replaces the traditional construction, characterizing the identity of the department stores.

La Samaritaine - the Samar as it was named by the public - will, therefore, acquire a new 'trendy' look, so becoming one of the most sought-after stores in Paris. Two particularly 'exuberant' polychrome domes will close the building scandalizing and creating many moods in the town.

Soon, Ernest Cognacq imagines the extension of the second store enriching it with a new façade on the Seine. This involves the closure of the rue Prêtres-Saint Germain-l'Auxerrois, as well as the purchase and destruction of the buildings located between the road and the riverbank. The Paris municipality expresses a favourable opinion on this important transformation as long as the domes of Jourdain are demolished and the new façade is planted backwards from the road alignment, to widen the intersection at the Pont-Neuf.

In 1922, Frantz Jourdain defines a first project that is radically rejected; it is then joined in 1925 by Henri Sauvage, to whom the task of definitive is finally assigned. However, the second project

is also rejected due to the presence of an exposed metal frame, the polychromy of the facades, the effect - deemed unpleasant - of two bow-windows on the main front and a top lantern[6]. In May 1926, a third project is drafted by Sauvage which envisages a self-supporting counter-façade characterized by the presence of large stone blocks, the replacement of the lantern with a terrace accessible to all and the downsizing of the decoration. The new Samaritaine thus become a reference for Art Deco architecture:

> emblematic, unitary and of immediate readability, the Senna side facade of the Magasin No. 2 thus conceals the backbone of a very complex reality (Cabestan 2013, 51)

The department store is again extended in the 1930s along the rue de Rivoli. At the request of Gabriel Cognacq, grandson of the founder, the *Magasin* No. 3, is built in the block placed between the Rivoli, Pont-Neuf and Boucher streets. The building permit is issued on 31 December 1929 and the construction site starts on 2 February 1930. The edifice, a masterpiece in terms of prefabrication and assembly, is carried out by the company Lange, Escande et Cie which concludes the works in just eight months, without ever stopping retail. Designed once again by Henri Sauvage, the façades draw clear inspiration from those just built on the Seine but, free from the constraints imposed there, are characterized by lightness and elegance. They inaugurate an urban aesthetic that is no longer the Haussmannian one (Fig. 2). A colossal rewriting that marks the start of an urban sequence of imposing and authoritarian facades that would have been followed by the *Magasin* No. 4.

After Sauvage's death, the extensive building harmonization program continues. Jourdain starts the construction of the last tranche which foresees the rebuilding of the front built on the rue de Rivoli. After his death, his collaborators Louis d'Escrivan and Louis-Marie Charpentier conceive the project for the conversion of the complex consisting of a group of buildings of the 19th century. Alas, the onset of the economic crisis will put a brake on these intentions. The already advanced project of reconstruction of the façades is not realized and the *Magasin* No. 4 remains a succession of four *pre-Haussmannien immeubles de rapport* of a certain aesthetic interest, but certainly not a rarity in the capital.

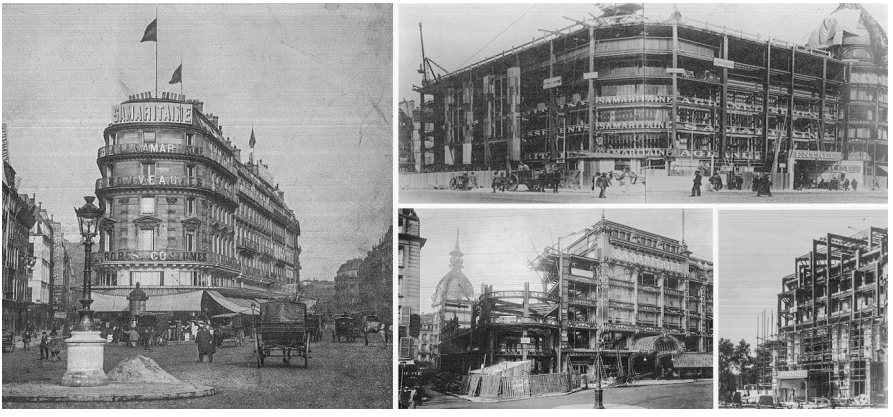

Figure 2. Construction phases of La Samaritaine. Source: (La Samaritaine, 2015)

[6] The municipal authorities were concerned about the impact of this new building on the skyline of the right bank of the Seine and co-visibility with the Louvre.

If in 1990 buildings Nos. 1, 2 and 3 are listed in *the inventaire supplémentaire des monuments historiques*, the intrinsic value of the edifices belonging to the *Magasin* No. 4 did not justify a priori any opposition in terms of new projects, moreover planned but interrupted since the crisis of 1929.
The continuous transformation that governed both the architectural life of the Samaritaine and the entire area, abruptly stopped for incidental causes, could no longer be delayed, especially because of an economic revitalization of the department store, long affected by a process of 'ageing' and decay.

2. RECENT METAMORPHOSIS AND NEW GRAFTS IN HISTORIC LANDSCAPE

In the 1990s, despite several attempts at renovation, the image of the department store is lowering and some financial difficulties arise. In the decade 1990-1999, the Samaritaine suffers a 6% decrease in its turnover while the four other Parisian department stores are up 9%. In 2001, the luxury group LVMH (Louis Vuitton Moët Hennessy) already the owner of Bon Marché, purchases the Samaritaine and inaugurates a new stage in the history of the Parisian department store. Notwithstanding the decision to keep the commercial vocation unchanged, the retail business is shortly after suspended and stopped on 15 June 2005 following studies, which highlight the lack of security of buildings in the face of the risk of fire. At the time, La Samaritaine occupies 75,000 m2 in the heart of Paris, employs 1,400 people and is visited by 10,000 to 20,000 customers per day.
Its sudden closure is a trauma, first for the employees but also for the surrounding neighbourhood, which loses much of its vitality (APUR, 2007). The objective of LVMH is then to renew the activities and change the image of the Samaritaine to attract the young and active clientele.

The department store's grip is further reduced. In 2002, the *Magasin* No. 1 (16,000 m2), long unoccupied, is rented to the Kenzo and Sephora brands (two subsidiaries of LVMH), the Zara group and to offices. The Samaritaine then focuses on its main stores: the Magasins No. 2 and No. 4, (75,000 m2 in total).
A bold and innovative project is therefore conceived by the architects Kazuyo Sejima and Ryue Nishizawa of the Japanese studio SANAA, winners of the Pritzker Architecture Prize in 2010. The program aims to increase and relaunch the image of Paris as the capital of luxury. The redevelopment of the facades and interior spaces, inspired by the original idea of the architects Jourdain and Sauvage, involves the modernization of the commercial spaces and the construction of offices, a luxury hotel (80 rooms), a restaurant with terrace, a nursery for 60 children 7,000 m2 of social housing: (96 homes). A project based on the diversity of function, architectural forms and construction methods.
A conservative approach is followed for the historic façades of *Magasin* No. 2, the multicoloured glazed tiles of the interiors, the glass roof, the monumental staircase and the furnishings; while a contemporary project is conceived for the façades and buildings of Quai du Louvre and Rue de Rivoli, marked by the use of new materials and design elements.
The SANAA project has sparked a series of controversies especially from various associations - in particular, the *Société pour la protection des paysages et de l'esthétique de la France* (SPPEF) and SOS Paris, who have appealed against the project. The latter was considered in contrast to the *plan local d'urbanisme* (PLU) which requires that each new construction would be integrated into the existing urban fabric, taking due account of the morphological and typological peculiarities of the neighbourhood, as well as that of the existing façades and roofs.

> Can we destroy an almost whole block, in the heart of Paris, to build a private commercial building? (Gady 2014);
> For LVMH, as for many industrialists and local authorities who are now playing the same game, starchitecture is a pretext as much as a tenure if not all-risk insurance. It thus relegates architecture to the rank of a consumer product (Chemetov 2014)

are just some of the criticisms brought to the project.

Indeed, the transformation of this important symbol of Paris had already foreseen numerous exchanges among the parties involved. Several meetings, conferences, studies were taken, to guarantee a broad debate on the changes that would take place. Also, in June 2011, two feasibility studies focusing on the compatibility of Sanaa's project with the requirements of urban architectural protection were carried out under the direction of eminent personalities. The one directed by Jean François Cabestan confirmed the validity of the design proposal, recognizing a particularly high historical and patrimonial awareness in support of the analysis of "what must be maintained, what could evolve and what must change" (Cabestan 2011, 121). The logic of the conversion of the Samaritaine and the idea that its rebirth could be based on a contemporary contribution to the image of the old department store in the Parisian public space appeared more than legitimate. It was also added that the transformations were an integral part of the history of this building, as well as the 'transparent' solutions, already widely adopted in the recent architectural history of Paris, even in the historic centre.

Otherwise, the second report drawn up by Pierre Pinon and François Loyer, considered the proposal unacceptable, since it disregarded the characteristics of the urban fabric. Old edifices would be replaced by a new one characterized by a very long and high facade, so destroying the rhythm established by the parcel breaks (Pinon & Loyer 2015). The dimensions of the new building - 75 m in width and 25 m in height - differed substantially from those of an ordinary edifice - on average 15 m wide and about 17 m high - even though its function will be (offices, housing, shops, etc.).

The large undulating glass façade with serigraphies that stands today as a scenographic urban backdrop on the rue de Rivoli was at the core of the criticisms (Fig. 3).

Figure 3. The new Saana's project for Magasin No. 4. Source: (Author 2020)

The so-called 'shower curtain' was the cause of a long procedural battle. As a consequence, in May 2014, the building permit for this project was annulled. However, while legalities proceeded, the work continued and the original four buildings were torn down. The annulment went then to appeal, and in June 2015 LVMH won.

Ultimately, whatever was the purpose of these procedures, they raised many questions regarding the place of architecture contemporary in old centres. They brought out new blames around the forms of expression of contemporary architecture.

AS A 'TEMPORARY' CONCLUSION: CRITICISMS AND MISUNDERSTANDINGS ABOUT CONTEMPORARY ARCHITECTURE IN HISTORIC CENTRES

The case of La Samaritaine perfectly falls within the longstanding, rough and always open debate over the reconciliation of heritage conservation and development. A debate related to the quality and the character of the architectural insertions in historic areas, which especially in the last years - in parallel with the enlargement of heritage conservation significance, from the mere protection of the legacy of the past to the idea of sustainable management of urban growth - has become a timely research topic. However, the notion of quality of the architectural act is not easy to define, but certainly includes some essential requirements such those related to the prior analysis of evocative, cultural and formal values of the place, the concept of durability, objective aesthetic rules, as well as its relevance (i.e. cultural, economic) to be evaluated and assessed based on the most effective community-based decision-making.

The definition of specific guidelines for a successful 'combination' of new constructions with the existing urban fabric, is unfortunately very problematic. Many authors agree that criteria can be used as points of reference or as a reminder list for applicants and evaluators, but they cannot ensure good - or avoid bad - design. In general, the approaches followed in the insertion of the new in the old are varied and constantly evolving: about architecture, they can refer, according to Giovanni Carbonara, to the principles of autonomy/dissonance, assimilation/consonance or be based on the establishment of a dialectical relationship/reintegration of the images (Carbonara, 2011). All categories in which different worthy examples of design, showing a good equilibrium between the exigencies of modernity and that of the historicity, can be found. Besides, there are also special experiences, often aimed at the construction of an image useful to highlight the novelty of the place, turning it into a catalyst for people and activities to exploit in a commercial and marketing perspective.

Located in the centre of Paris - indeed in its hyper-centre, the rue de Rivoli - the Samaritaine, "last avatar of a brilliant, cheerful, somewhat carefree era […] unquestionably the ancestor of today's functionalist constructions" (Barré-Despond 1988, 194) seems to embody all the concerns of a *social milieu* - even culturally high - wary of contemporary architecture. To the latter is attributed the danger of the loss of identity of a historic centre increasingly attacked by homologation processes and 'sold' to mass tourism and to commercial gentrification.

The lack of sympathy for contemporary architecture becomes dislike when the contemporary project 'affects' the historical heritage, a legacy that belongs to the community (local, firstly); that heritage "whose loss constitutes a sacrifice and whose conservation presupposes sacrifices" (Chastel 2008, 62). It turns into a real rejection when the architect is a star architect and the design seems to be so subordinated to technology, so much as to lose any reference to the past. When the architecture is so light and almost immaterial as to seem to have

no connection with the context and poor durability. When, in comparing it to historical architecture, it is judged superficial and without underlying codes.
In reality, the *Magasin* No. 4 project - although it has made *tabula rasa* of the past, perhaps not pushing research enough towards a rewriting of the existing, yet possible - is unquestionably extremely refined and elegant. Today, having removed every yard fence, it appears in the definitive version respectful of the alignments and elevations of the close buildings, without clashing with their materiality made up of stone facings. Its aesthetics may not appeal to everyone, but the final judgment will be that of those who will enjoy it every day or maybe a few minutes. In any case, the much-contested façade seems to fit perfectly in the continuity of that will of the invention that was inherent in both its creators and the first owners of the Samaritaine. A vision that allowed to enrich the neighbourhood, characterizing it with an originality that is today perpetuated.

PAPER #3.18

BUILDING A MODERN ASUNCION: CONTRIBUTIONS OF THE HOTEL GUARANI IN THE CONFIGURATION OF A NEW URBAN SPACE

Julio Diarte[a,b], Elena Vazquez[a]
[a]Penn State University, University Park, PA, USA
[b]Universidad Nacional de Asuncion, San Lorenzo, Paraguay

ABSTRACT

The relative geographical isolation of Paraguay has always been an essential attribute of its cultural production, including its architecture. This condition has also made Paraguay a late and eclectic adopter of the principles of the Modern Movement in architecture. While Oscar Niemeyer's pavilion for the 1939 world's fair represented a hallmark in the definition of a Latin American Modern Architecture, some of the first examples of this type of architecture in Paraguay appear just in the 1950s. Overlooked for decades, recent investigations developed in the last years have studied the architectural production in Asuncion during the mid-twentieth century through the lens of historical, sociopolitical, and aesthetic considerations. There are two modern buildings in Asuncion, the capital, which can be considered of utmost importance for their scale and their meaning as cultural artifacts: the *Colegio Experimental Paraguay-Brasil* —designed in 1952 by Affonso E. Reidy— and the *Hotel Guarani* —designed in 1956 by the Brazilian architects Adolpho Rubio Morales, Rubens Carneiro Vianna, and Ricardo Sievers. While several studies have investigated the first, the *Hotel Guarani* has received much less attention despite its strategic location in downtown Asuncion and introducing novel architectural strategies in terms of urban space configuration. In this paper, through digital reconstruction and formal analysis of this emblematic case study, we analyze the architecture of the building with a focus on the design strategies that defined new urban spatial relationships between the building and the city of Asuncion. Through a formal reconstruction of the project, we identified several architectural concepts such as permeable street-level floorplan, semi-public corridors, and large overhangs. We argue that these design strategies contributed to the new architectural language of the incipient Paraguayan modern architecture.

KEYWORDS

Modern architecture; Paraguay architecture; urban space.

INTRODUCTION

The relative geographic isolation of Paraguay has always been a trait represented on its cultural and architectural production. This condition can also be reflected in its late and eclectic adoption of the principles of the modern movement in its architecture. Scholarship in Latin American modern architecture, for instance, usually frames the story of modernism in the continent from Le Corbusier's 1929 visit to South America to the 1960's completion of Brasilia (Fraser 2001). However, some of the first examples of what could be characterized by modern principles in Paraguayan Architecture do not appear until the 1950s. Overlooked for decades, recent studies have sought to investigate the impact of modern architecture in Paraguay. A recent publication has presented an extensive catalog of buildings dated from 1948 to 1985 (X et al. 2018), providing a panoramic view of the architecture in Paraguay with a focus on buildings that followed design principles of

modern architecture or presented a modern trait. However, there has been little discussion on the contributions that some of these buildings had in the development of a new architectural language with modern principles and its impact on the configuration of new urban spatial relations in Paraguayan cities.

There are two modern buildings in Asuncion, the capital, which can be considered of utmost importance for their scale and their meaning as cultural artifacts that represent the sociopolitical context in which they were built: the *Colegio Experimental Paraguay-Brasil* and the *Hotel Guarani* (Figure 1). The first, a school designed by notorious Brazilian architect Affonso E. Reidy, has been extensively analyzed both in its formal traits and its contribution to modern Paraguayan architecture (Diarte 2009; I. Rivero and Delpino 2009). The second, the *Hotel Guarani*, has received much less attention despite its strategic location in downtown Asuncion and introducing novel architectural strategies in terms of urban space definition (Diarte 2015). The *Hotel Guarani* was designed by Brazilian architects Adolpho Rubio Morales, Rubens Carneiro Vianna, and Ricardo Sievers, who won the international competition for its design, the first of its kind in Paraguay in 1956 (Morra 2010)[1]. This paper presents a formal analysis of the *Hotel Guarani*, identifying its prominent architectural features that help define a new modern urban form and space in Asuncion. Furthermore, we illustrate the surrounding area of the *Hotel Guarani* and deliberate how its design strategies could have influenced subsequent buildings. The main argument of this paper is that this emblematic building with distinct modern design principles gave shape to innovative design approaches, especially in the transformation of the urban space. This paper contributes to the growing body of research on Latin American architecture by discussing a well-known symbol of modern design and the new ideas it brought to the language of Paraguayan architecture.

Figure 1. View of the Hotel Guarani from the Plazas in the late 1960s. Source: (ABC Color 1967)

1. BACKGROUND OF THE PROJECT

The development of modern architecture in Paraguay is closely linked to the country's regional relationships (C. I. Rivero 2016); thus, to understand its origins, one must look at the sociopolitical conditions of the region. Paraguay is surrounded by three countries, Argentina, Brazil, and Bolivia, the first two being prominent players in exerting cultural influence throughout the region–Buenos Aires as the unchallenged cultural capital before World War II and Brazil emerging as a strong contester in cultural supremacy during the Cold War (García 2014). The 1950s then represents, in Paraguay, a shift in regional relations from Argentina to Brazil. However, modernist principles were introduced into Paraguay's architectural production through other vital players in the region. Rivero (2016)

[1] Morales, Vianna, and Sievers received an award of $4,000 and the contract for the design development of the project and the supervision of the construction. The 2nd place ($2,000) was awarded to the architect Jaime Larrain Valdez and his collaborators, Julian Larrain Echeverria, Hernan Martinez, and Federico Lorca, all of them from Santiago de Chile. The 3rd place ($1,000) was awarded to the architect Jose de Souza Reis from Rio de Janeiro, and the 4th place ($700) was awarded to the architect Ruben Dufan from Montevideo (La Tribuna 1957). All of them, except for the 4th place of which we have not found information until the submission of this article, were highly renowned architects in their countries. This situation evidences the importance of the contest in the region.

discusses the influence that Brazil, Argentina, and Uruguay had in the development of modern architecture, describing how modern ideas were exchanged among these southern countries.

According to local researchers, there were two critical moments in the construction of a Paraguayan Modern Architecture. First, the return of Paraguayans instructed in the architecture school of Montevideo (FADU-UDELAR)[2] in the 40s and 50s; and second, the arrival of renowned Brazilian architects to Paraguay such as Affonso E. Reidy. The return of Paraguayans graduated from the FADU-UDELAR helped form the first architecture school in Paraguay in 1957 (at the *Universidad Nacional de Asuncion*). Nevertheless, two of the most iconic buildings of modern architecture in Paraguay have been influenced by the presence of Affonso E. Reidy in Paraguay, either as the designer himself —the *Colegio Experimental Paraguay-Brasil*— or as part of the jury that selected the winning design —the *Hotel Guarani*.

As mentioned before, the *Hotel Guarani* resulted from an international architecture competition organized by the *Instituto de Prevision Social* (IPS). The IPS is a government institution that played an essential role in the construction of public buildings with modern traits. Arturo Herreros, for example, the first architect that graduated from the architecture school in Paraguay in 1963 (Diarte et al. 2019), led the architectural design of important buildings such as the (Diarte et al. 2019)Hotel Acaray in Ciudad del Este in 1965 and the Hotel Casino San Bernardino in 1974. The contest for the Hotel Guarani, first of its kind, called for a design that would become a "symbol of modernity" and attracted 28 entries from different countries. Tomas Romero Pereira—also an architect and former president of Paraguay with strong political connections—chaired the jury, which also had famous Brazilian architect Affonso E. Reidy. Reidy played a key role in the dissemination of Brazilian modernism within his role as architect-in-chief of the Engineering Department of the *Distrito Federal* city council of *Rio de Janeiro* (Rovira Llobera and Herrera Milek 2018). The building's inauguration was on September 11, 1961, on the founding anniversary of the dictator's party. The 15,000 m2 competition brief ended up being a 23,753 m2 of built surface, and the building became an icon for the dictatorial regime that governed the country from 1954-1989 being included even in one of the local currency bills[3].

Up to now, the paper described the broader context and meaning that the *Hotel Guarani* has as a cultural and social artifact. What follows now is an analysis of the architecture of the building with a formal methodological approach centered in its aesthetic, geometric, and constructive nature. The proposed research approach relies on means of graphic representation, such as photographs and drawings—means that architects use to design—to uncover meaning and intentions (Gastón 2010). Data for this study was collected through archival work, photographs, and digital reconstruction of architectural blueprints of the original design. For this study, the architectural project becomes the center for extracting design strategies. In this way, we intend to unveil and discuss design intentions and ideas observed in the architectural project, particularly those concerned with the definition of the urban space.

2. A NEW RELATIONSHIP BETWEEN BUILDING AND THE URBAN SPACE

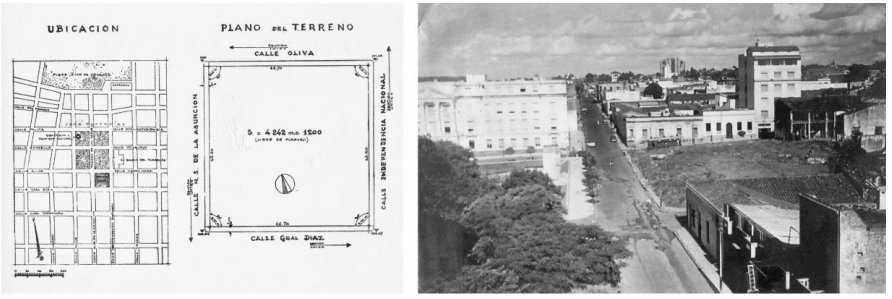
The *Hotel Guarani* is strategically located in downtown Asuncion: in front of a group of four *Plazas* in which the neoclassic *Panteon de los Heroes* (1863) is located, and near the *Banco Nacional de Fomento* (ca. 1940 and formerly

[2] The full name is Facultad de Arquitectura, Diseno y Urbanismo de la Universidad de la Republica Oriental del Uruguay, Campus Montevideo

[3] The total cost of the venture cost around US$4 million representing almost US$35 million of today's value

known as *Banco del Paraguay*), another neoclassic institutional building (Figure 2). The design of the hotel follows the modern typology of a tower over a horizontal base, that can be seen in other iconic buildings such as the Lever House in New York City by Gordon Bunshaft in 1948. The horizontal base contains public programs such as stores, an 800-seats theater, a restaurant, and a terrace with a playground and a pool. The tower on top of the horizontal base is a prism with a triangular base, which also carries over to other design elements such as the columns and terrace design. The tower houses all the 170 hotel rooms and a restaurant at the top with views over the city and the Paraguay river. The program has not changed from its original function as a hotel, although the building has suffered periods of abandonment until the last recent renovation in the decade of 2000 that executed substantial interventions in its architecture.

Jose G. Rodriguez de Francia—the dictator who ruled Paraguay after its independence in 1811 until 1840— established the orthogonal-like geometry of the urban fabric of downtown Asuncion in the decade of the 1820s intending to reorganize the organic development of the city (Gutierrez 1983). The site for the hotel occupied a whole block of this fabric in the hearth of a city characterized by low-rise buildings—mostly private houses—of continuous and modest facades. The largest public building in the perimeter of the four *Plazas* was the *Banco National de Fomento,* built in the 1940s and designed by the renowned Argentinian architecture office of Sanchez, *Lagos y de la Torre*[4]. The relation between the surrounding buildings and the streets around the Plazas was very restricted for three reasons: (a) their design principles—a combination of colonial and neoclassical types of architecture mostly closed to the exterior and turned to inner courtyards to counteract the crude hot and humid local climate; (b) the construction system with which the buildings were erected—load-bearing masonry walls with limited openings in the exterior facades; and (c) the material resources available at that time—the use of glass, steel, and concrete was very limited in Paraguay during the mid-twentieth century, thus, the openings were very limited. In this context, the Brazilian architects who won the international contest for the design of the *Hotel Guarani,* proposed a completely opposite approach that relied on the technological advancements in construction materials and techniques available in Brazil at that time[5].



(a) (b)

Figure 2. (a) Site plan and (b) aerial view of the site in the early 1950s. Source: (a: (Instituto de Prevision Social 1956); b: Javier Rodriguez Archive)

[4] Sanchez, Lagos y de la Torre designed the Cavanagh Building in Buenos Aires in 19

[5] Paraguay did not produce cement until 1969 when the government inaugurated the Industria Nacional del Cemento and did not produce steel products for construction until 1970 when the Aceros del Paraguay was inaugurated. Before that, most of the cement and rebars were imported from Argentina.

3. UNVEILING THE ARCHITECTURE OF THE HOTEL GUARANI BUILDING

The following section describes and considers the architectural features of the horizontal base and the tower in relation to the urban space. To illustrate the architecture of the building, Figure 3 shows the graphic reconstruction of the basement, street level, and +2 level floorplans of the horizontal base, and +4 to +12 levels floorplans of the tower. The reconstruction of all these drawings followed the original design of the building[6].

The organization of the street level floorplan was composed by three main areas occupying the whole block and separated by internal corridors—shaded in light gray in Figure 3-b: (a) the primary access, lobby, and restaurant on the northwest; (b) a small block of stores on the east; and (c) a second block of stores and service areas in the south. The configuration of the internal corridors going through the building from east to west and north to the south allowed anyone who was walking through three of the four surrounding streets to enter the building. This permeability of the building was a completely new urban phenomenon for Paraguay; however, other architects in Sao Paulo, previously adopted this strategy with great success in mix-use buildings[7]. In Figure 3-b, we emphasize the contrast between the openness of the hotel's street-level floorplan in comparison to the surrounding buildings.

Following this idea of permeable street-level floorplan[8], and to reinforce the autonomy of use of the different parts of the program, the architects separated the main entrance of the hotel—that includes a small parking area for the guests—and the entrance to the 800-seats theater (Figure 2-a). The main entrance faces the *Plazas*, and the entrance to the theater is in the northeast corner of the block in direct connection to the street. The lobby of the hotel is a two-levels inner courtyard accentuated by six monumental triangular-based concrete columns and a straight stair on the side that connects the lobby to the level +1 of the horizontal base—the conference rooms are in this level. Overall, the street level floorplan of the horizontal base is key in articulating the different components of this multifunctional building—hotel, theater, restaurant, conference rooms, and shops—their requirements, and hierarchy in the program list. Next, we will stress the main features of the following levels of the building.

Figure 3-c shows the floorplan of the +2 level, which is the roof of the horizontal base. Similar to the Lever House Building in New York City, the roof of the horizontal base occupies the whole block and works as a terrace and leisure area of the hotel that is restricted only to their guests. Triangular shapes dominate three of the four main elements in the terrace. The first triangle is the off-centered tower of the hotel rooms; the second, an exterior lounge covered with a flat roof and a small enclosed space; the third, a triangular void in the horizontal base roof that gives room to a courtyard in the conference rooms level; and lastly, an irregular-shaped pool facing the *Plazas* and exposed to the sun all year-long.

It is somewhat surprising how the architects changed the criteria between the design of the floorplans of the horizontal base and the design of the terrace. The first follows an orthogonal geometry, and the second has a less structured composition of triangular-shaped elements. The triangular shape of the tower, for example, is almost imperceptible in the geometrical disposition of the columns in

[6] The current Street level floorplan of the hotel looks different from the original due to changes in the program implemented by successive tenants.

[7] The Conjunto Nacional building in Sao Paulo, Brazil, designed by David Libeskind in 1952

[8] The architects took a similar approach in subsequent design projects. In this sense, two of the most interesting are the contest in 1957 for the City Hall building of the city of Campinas, Brazil, designed by Viana and Sievers (Instituto de Arquitetos do Brasil - Nucleo Regional Campinas 2015) and the contest for the Legislative Assembly of the Sao Paulo State in 1962 designed by Morales, Viana, and Sievers (Machado Marquez Gabriel 2013) The architects received the 1st place in both contests and the buildings exist until today. The Campina's City Hall building, for example, shares many formal and structural elements with the project for the Hotel Guarani.

the lobby area of the street level floorplan. A possible explanation for this might be that the architects wanted to interrupt the regularity of the orthogonal structure of the urban space by placing triangular-based elements that would be unique in the context, especially for the hotel tower. Another possible explanation for the triangular-based shape of the hotel tower is that this shape allows more rooms to have a better view of the city and the river (Figure 3-d). This combination of different forms in a less structured pattern is a trend in the work of modern Brazilian architects, especially in the works of Oscar Niemeyer, who usually combine regular-shaped buildings with irregular-shaped connectors. The Ibirapuera Park, designed by Niemeyer in 1954, is an excellent example of this design strategy.

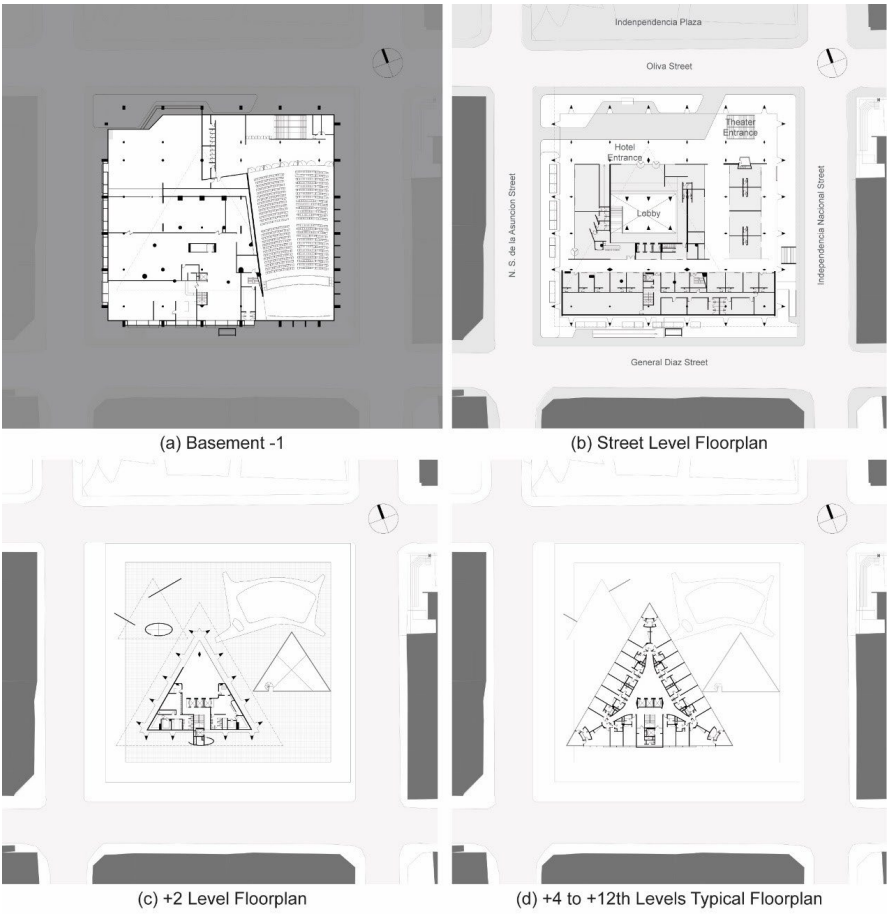


Figure 3. (a) Basement; (b) Street Level, (c) +2 Level; and (d) +4 to +12th Levels Floorplans

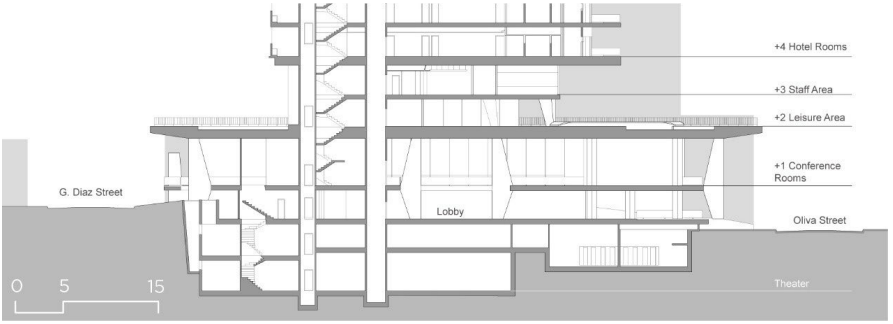

Figure 4. North-south section of the building base.

Turning now to another view of the horizontal base, Figure 4 shows a longitudinal cross-section of this component of the project. As discussed above, the horizontal base is a critical element of the project and controls the transition between the exterior and public urban space and the interior space of the hotel. The horizontal base roof is also a structural element that redistributes loads of some of the columns of the triangular-based tower to the lower levels. The base also compensates for the height difference between the *G. Diaz* and *Oliva* streets, as shown in the section. Another feature that stands out from the section is the significant length of the overhang on the four sides of the square-shaped horizontal base. This overhang creates a type of intermediate space between the street and the façade of the building, and although it is not entirely walkable, it resembles the traditional *"Recova"* or semi-open gallery of the colonial-times buildings in downtown Asuncion. While it is unlikely that the designers took inspiration from the colonial-style galleries, it would be safe to assume that the introduction of the overhangs as an intermediate space shows sensitivity towards the local climate[9]. The section also shows the use of double-height columns in the lobby, similar to those used in the perimeter. The following section will focus on other aspects of the building in relation to the surrounding *Plazas*.

4. POTENTIAL REPERCUSSIONS ON SURROUNDING BUILDINGS AND THE PUBLIC SPACE

The information in Figure 5 shows that there has been a steep rise in the number of modernist-style buildings around the *Plazas* since the inauguration of the *Hotel Guarani* in 1961. The axonometric reconstruction offers some information about 40% of the total buildings around the *Plazas*. Foreign architects designed most of these buildings[10] and some of them—especially the *Banco de la Nacion Argentina* and *Banco Sudameris*—share some architectural features with the Hotel Guarani regarding, for example, the openness of the street level floorplan of the building in relation to the exterior urban space. Nevertheless, it is not clear if the *Hotel Guarani* was the actual reason these newer buildings were designed with a more open configuration in the street level, or it was instead a general trend in the

[9] Asuncion's climate, according to the Köppen–Geiger classification system is hot and humid.
[10] Although there are buildings designed by Paraguayan architects that can be considered within the principles of modern architecture in downtown Asuncion, all of them were built after the 1970s. The first group of Paraguayan architects who graduated from the School of Architecture at the National University of Asuncion was in 1963. After this, their participation in the construction of buildings in Asuncion increased significantly.

design of institutional buildings that followed the principles of the "International Style" at that time. The question remains, nevertheless, what was the actual benefit of the application of this concept to the urban space in downtown Asuncion in the late 1950s?

A possible answer to this question can be found in work done by researchers who have analyzed the significative concessions of "private space" towards urban "public space" in examples of modern architecture. The dissertation of Andrea Parga (2017), for example, investigated the work of Gordon Bunshaft at the Skidmore, Owens, and Merrill's architecture office in New York City. Parga suggest these concessions did not only have an economic reason—the buildings could be taller if they granted private space to the public space, thus more space to rent—but also an architectural intention that makes these buildings much better articulated to their surroundings and therefore "producing" a new type of—privately owned—urban space. Although we cannot draw a direct comparison between the Hotel Guarani and Bunshaft's buildings in Manhattan, we believe the Brazilian architects did not ignore the benefits of this strategy to the urban quality of their buildings and even the benefits related to climate conditioning. Later projects in Brazil by the same architects demonstrate this was a recurring strategy, especially the City Hall building in Campinas (1957) and the Legislative Assembly of the Sao Paulo State (1962).

CONCLUSION

The present research aimed to analyze the architecture of the Hotel Guarani, with a focus on novel design strategies that defined new urban spatial relationships between the building and the city of Asuncion. Through a formal reconstruction of the project, we identified several architectural concepts such as permeable street-level floorplan, semi-public corridors, and large overhangs, that contributed to the new architectural language for the existing Paraguayan architecture. With this paper, we aim to contribute to the literature on Latin American Modern architecture, in general, and to the construction of a history of Paraguayan architecture—in particular. Furthermore, this paper presents one of the first accounts of the Hotel Guarani's architecture and the first comprehensive assessment of the Hotel Guarani's architectural features with a focus on its relationship to the urban space.

A limitation of this study is that we relied exclusively on the documents and architectural floorplans found in the archives of the Instituto de Prevision Social, and on local publications. It is hard to account for original architectural intentions and ideas behind the design of the building without having, for instance, access to documents from the competition. Furthermore, there is limited information on modern buildings built after the Hotel Guarani, to asses the impact it had in design language adopted by the subsequent generations of Paraguayan architects. However, further studies could do a formal analysis of buildings with modern traits build after the Hotel Guarani, comparing architectural features and design principles used.

A somewhat secondary but significant impact the Hotel Guarani had was the technological transfer that supposed the introduction of new materials and technologies into Paraguay's construction industry. The materials imported for the construction of the Hotel Guarani permitted the successful continuation of the works at Reidy's Colegio Experimental Paraguay-Brasil (Barrail, personal communication, December 15, 2015). In a way, the know-how of concrete construction technologies helped introduce a new set of possibilities in terms of architectural language: open floorplans, large overhangs, monumental structures, high-rise buildings, among others. Open floorplans, then, allowed designers to introduce permeability into public buildings with layers between public and private spaces.

PAPER #3.19

THE ARCHITECTURAL SPANISH IMPRINT IN CHINA. WHY AN "ALHAMBRA-STYLE" MANSION IN SHANGHAI?

Álvaro Leonardo Pérez[a]
[a]Universidad de Alcalá de Henares, Madrid, Spain

ABSTRACT

The history of an old mansion with neo-Arab Spanish style elements in the vibrant, ever-changing city of Shanghai is intertwined with the lives of the two remarkable men: the sole Spanish architect in the city of his day, Abelardo Lafuente García-Rojo (Madrid 1871–Shanghai 1931) and that of Antonio Ramos, the Spanish tycoon who introduced motion pictures in China and was then known as "the king of cinema". A long-forgotten story, its recent discovery reveals the interests and desires of the cultural mix that was the multinational community of what was the most open city of the continent. After launching his career in Manila, the Philippines, in 1898, Lafuente worked almost uninterruptedly in China from 1913 to 1931. Either on his own or collaborating with partners, in these almost two decades in Shanghai, Lafuente expressed himself in a variety of architectural styles. His wide-ranging list of clients included Jewish businessmen, bankers, Spanish tycoons, and also the most important Spanish religious missions in Asia. For ten years, Lafuente was commissioned work in several cities in China from the most renowned hotel chain in Asia, "The Hong Kong and Shanghai Hotels Limited". Furthermore, he single-handedly managed to introduce the Spanish neo-Arab style in several buildings which today are still standing in the city, although he is currently not identified as the architect. His little-known professional career in China is a case study of the cultural melting pot of the city of Shanghai. This article aims to showcase the four buildings commissioned in Shanghai by Antonio Ramos: two cinemas, an apartment building and last, but foremost, his Alhambra-inspired summer family mansion for which he imported tiles from Spain.

Abelardo Lafuente; spanish architects in China; Shanghai; neo-Arab style; spanish tiles.

INTRODUCTION

Present day Shanghai is undoubtedly a modern, cosmopolitan and fast-paced city, one of the largest metropolises in Asia and the world with 25 million inhabitants, with urban modernizations and architectural renovations in the last decade that have progressed at a speed that Europe can't even imagine. One expects to find streets full of billboards, state-of-the-art buildings intermingled with Chinese temples, and probably maddening traffic resulting from the high population density and the various means of transport used in the country that so differ from our continent. Neither outlandish nor false, the truth is that this same description was applied to the city a hundred years ago -in 1920- in the surprising and dynamic history in the peak of the Golden Age of this metropolis, between 1907 and 1927, the two decades around which this article is centered. This urban history started seventy-eight years earlier with China's defeat in the First Opium War at the hands of the British which resulted in the

signing of the Treaty of Nanjing in 1842. This treaty opened the city to the English, along with four other coastal cities (French 2010). Unfortunately, few are aware of the British and foreign influence on the country's most multicultural city, as a result of the British, American and French domination between 1860 (after the Second Opium War) and 1949 (with the coming to power of the Communist Party). But absolutely no one could imagine that strolling through the Hongkou neighborhood, known as the Jewish ghetto during World War II and very little exposed to foreign tourism, you may perchance come upon what could be considered the jewel of Spanish neo-classicist architecture in China, and until 2010, a forgotten part of the history of both countries. The building there located is the only still standing example of neo-Arabic Spanish style of the twentieth century, miraculously preserved without having been listed among the Cultural Heritage sites despite its paradigmatic uniqueness, nor having undergone any conservation works to help mitigate the passage of time. The mansion was built between 1923 and 1924 by the only Spanish architect established professionally in the city, Abelardo Lafuente García-Rojo (Madrid 1871-Shanghai 1931) for Antonio Ramos Espejo (Alhama de Granada 1878-Madrid 1944), a Spanish businessman also based in Shanghai known for laying the groundwork of the film industry in China. These Spanish adventurers and entrepreneurs made use of this fruitful professional relationship to advance on the other side of the world and to succeed in their respective disciplines as no one had ever done in China. All this happened at the dawn of a vibrant multicultural society, when, together with a small but select group of fellow Spaniards formed by members of the clergy, lawyers, businessmen, artists, writers, journalists or "pelotaris", under very adverse conditions, they managed to flourish during decades.

This article will attempt to reveal for the first time the fascinating history that intertwined the lives and careers of two of the three most influential Spaniards in Shanghai in the first half of the twentieth century. Their names are almost forgotten by history, save for a brief mention in a posthumous work of Vicente Blasco Ibáñez, volume II of "The Trip around the World of a Novelist" (Blasco 1924). In the chapter dedicated to Shanghai, Blasco refers to the two men, an architect from Madrid and a businessman from Granada who introduced cinema in China, as the cornerstones of the small Spanish population living in Shanghai. Lafuente built not only cinemas for Ramos, but also commercial properties, and his personal mansion on the outskirts of the city. In each of those buildings, Lafuente employed a style that was personal and unique for the city, with a guiding theme reminiscent of an architecture that Spain at that time exported to the world, an architecture that represented the Iberian culture in stark contrast to other European cultures of remarkable world influence. This article traces the connections between the Spanish cinema tycoon, owner of the "Ramos Amusement Company" a successful business in Shanghai, and the professional trajectory of Abelardo Lafuente. In the 1920s and 1930s, Lafuente designed many of the most sophisticated and influential sites in Asia´s most cosmopolitan city, including spectacular hotels ballrooms, social clubs, banks or mansions.

> Lafuente was a self-taught architect, and to date, there is no documentary proof of his university studies in either Madrid or Manila. His extensive non-formal training and experience in construction was tied to his father's career as Manila's interim municipal architect and continued until his father's death in 1900. Subsequently, he worked in the construction field in Manila for 13 years. There is no clear evidence that Lafuente was influenced by the European Beaux-Art tradition. Rather, his unique architectural designs are

> reminiscent of the eclectic and historicist style of nineteenth-century Spain. The question of how he succeeded in capturing the attention of the heterodox Jewish community, which was the wealthiest class in Shanghai, as well as the city's sparse Spanish community with his unorthodox style is an intriguing one. The answer to this question would yield insights regarding an exceptional architect with a unique career. Lafuente is particularly remarkable given his origins in Spain, a nation that was evidently retreating from the global stage at the beginning of the twentieth century. (Leonardo Pérez, 2019b)

Antonio Ramos, who would later be known in the city as the "King of the cinemas", arrived in the city in 1903 with nothing but a projector, knowing, after his stay in the Philippines, that exhibiting films in China would be an absolutely novelty. It took him several years to establish himself, but from the 1910s he controlled the entire emerging Chinese film industry with a heavy hand (Toro, 2012b). He started out projecting films, then went on to convert rented rooms into screening rooms, and eventually built the theatres. By the time he had started a chain of seven cinemas in different parts of the city with his partner -with the same last name as him-, he was even producing his own films with both foreign and Chinese actors. Together with a third Spanish partner named Goldenberg, Ramos, who was by then one of the main players in the film industry, showed some of the first American films in Shanghai. They would buy these American movies, like Charlie Chaplin's, from the black market. This was enormously profitable but also angered the American exhibitors who had wait to legally purchase the films to screen them in their theaters. Tensions in the film industry reached a fever pitch when in 1922 his partner was murdered in one of his theatres, the Olympic Theatre-Cinema. The murder was never solved. With his family now in danger, Ramos hastily left the city. These events, coupled with the social and economic unrest the city started experiencing in 1926, had Ramos decide to sell or lease all of his properties and companies in China and return to Spain as a millionaire. With the fortune made in China, Ramos settled in Madrid with his family, bought a plot on the Gran Vía and built the Rialto Theater (1930, Gran Vía, 54 Madrid). Until his death in 1944, Ramos continued working in Spain in what he knew best: the world of cinema.

The first two works we shall cover in this article were the last ones designed for Ramos in China. They were built during the five-year period in which Lafuente developed his solo professional career in the city (1919-1924) under the architectural firm called "Abelardo Lafuente G Rojo" located at 6, Kiukiang Road and then at 13, Ezra Road (Leonardo Pérez 2019a). Both the mansion and the apartment building that still bears his name were designed and built at the same time. Both were part of the only large plot that Ramos initially bought in this northern area of the city. He decided to divide the acquired plot into two parts: the part that was larger and more exposed to the main street would be for his real estate investments, and the smaller more secluded plot with a chamfered corner, would be for his family's summer residence, since the Ramos family lived in the center of the city the rest of the year.

1. SUMMER MANSION FOR ANTONIO RAMOS (1923-1924)

Given its relevance and formal significance in its surroundings to the north of the modern and exuberant city of Shanghai, this large mansion stands out, as it is on a street where all the affluent people of the city moved to. Far from the centre of town, on the road leading to the northern railway station, as well as to the Rifle Range, Antonio Ramos bought a large corner plot on North Szechuan Road and Darroch Road, where he intended to build a

summer house with a remarkable peculiarity: it was to be a small replica of the Alhambra of Granada in Shanghai, as he wanted to remember his birthplace in this part of the world so far removed from his origins.

Figure 1. Ramos Summer Mansion (front view) circa 1930. Source: (Leonardo Pérez 2019 a)

Work on the mansion began in 1923. On the chamfered corner, the architect placed the main entrance giving it a unique significance on Darroch Road. The main façade was divided compositionally into three areas: in the centre, the door was flanked by two Nasrid-style columns, replicas of the Court of the Lions of the Alhambra, with remarkable ceramic spandrels (albanegas) composed of very colourful ceramic tiles of eclectic Spanish neo-Arab style. The central element of the composition was an overhanging balcony and three horseshoe arch windows. Originally, the most noteworthy element of the central body was the main dome of the house located on the stairwell that accessed the roof floor.

The second area of the main façade had a horseshoe arch on the ground floor with a simple scalloped arch, with a polylobed lintel and a polychrome ceramic tiled spandrel. On the first floor, were two windows with multifoil arches, its upper spandrels ornamented with Arabic geometric motifs of plaster.

The third area of the façade was composed on the ground floor by three narrow multifoil windows with spandrels decorated with Arabic plaster latticework. On the first floor, there was a series of five small windows in the same style. Due to the exterior composition, we can presume that the main room was located in the center of the façade and the other rooms were behind those smaller windows.

Figure 2. Ramos Summer Mansion (back view-veranda) circa 1930. Source: (Leonardo Pérez 2019 a)

The wrought iron gate where the cars or carriages entered through is located on the side of the street; to this day, 1924, the year of its inauguration, is still carved on this gate.

On the rest of the grounds, there was a private remarkably well-kept garden (according to the original photos), which served as a buffer between the mansion and the apartment building. The house was connected to the garden by five central horseshoe arches flanked by two stilted arches that served as the base of a large covered terrace on the first floor which opened to at least two of the upstairs rooms. It was framed by ten stilted arches.

The whole volume of the house was arranged around the large square Andalusian courtyard, which was closed off by a wrought iron gate and with Nasrid capitals crowning the columns such as those mentioned above. The patio was facing the side of the house opening to the entrance of the cars. Its appearance

and use in summer can be seen in the only photograph found of its owner with his son.

Figure 3. Ramos' Summer Mansion (back view-andalusian courtyard) circa 1930. Source: (Toro Escudero 2012 b)

As of today, the mansion is not accessible since it is inhabited by several Chinese families who moved there when the Communist Party came to power. I have been able to observe it in situ, and I can confirm that it is composed of a ground floor with a main drawing room which is now used as the common area for the families that live on both floors. I was also able to see that on the ground floor there are at least three rooms inhabited by three families. The upper floor is accessed by a marble staircase which still has its original wooden handrail carved with Moorish motifs. It ends in a corridor that has been closed off to give privacy to the families who use the four rooms on the top floor. All but one of the above rooms and bedrooms open to the Andalusian courtyard. The original mansion had a flat roof that is now in disuse. Its original domes have been lost and only the four pillars sustaining each former dome now remain as bizarre remembrance of the original shape which stood above them at the time.

In 2013 there was a disappointing attempt to restore its exterior façade by a private company which was supported by the Hongkou district government, but all the external elements that were supposed to be recovered were instead forever damaged. Recently there have been efforts to protect heritage in China, but sadly the building has never been listed in any conservation inventory. The truth is that buildings hailing from the times of foreign domination are just now beginning to be reviewed, whereas buildings in the Bund and surrounding areas that are attractive for international tourists and offer a high economic interest, have been first on the list for proper conservation and rehabilitation.

Figure 4. Ramos Summer Mansion (front view) in 2013. Source: (Leonardo Pérez 2019 a).

The study of this façade, in my opinion, should focus not only on the heterodox composition but also on the materials employed, as most of ceramic tile was certainly imported from Spain. Letters have been found that the architect sent to Francisco Valldecabres' company in Manises, Spain (addressed to Calle Pellicers 7 in Valencia).
The following is a detailed list of each area of the building in order to study the ceramic tiles used in the project. Four different decorative typologies were used in the elements of the walls, and only two in the tiling used as floorings. All of them are replicas of vegetal and decorative motifs similar to those made in the Alhambra of Granada. All of them are shown below.

- Tile type 01: (20x20 cm)
Places where it is used: entrance hall between the two front doors. Keystones of the horseshoe arches on the eastern façade. Covered porch on the ground floor of the eastern façade.

- Tile type 02: (20x20 cm)
Places where it is used: in the three main door spandrels, on the spandrels of the horseshoe arch window with simple scalloped arch with polychrome ceramic tiled spandrel. In the decorative rhombuses between the arches of the eastern façade on the ground floor.

- Tile type 03: (20x20 cm)
Places where it is used: this tile is only used on the exterior pavement of the main courtyard of the house.

Figure 5. Spanish-made tiling currently in place at Ramos' Summer Mansion. Source: (Leonardo Pérez 2019 a).

- Tile type 04: (20x20 cm)
Places where it is used: Main drawing room, exterior walls of the main courtyard.

- Tile type 05: (border 15x20 cm)
Places where it is used: this tile is only used on the exterior pavement of the main courtyard of the house and is used on the perimeter of the area of tile 03.

- Tile type 06: (border: 15x20 cm)
Places where it is used: this tile is always associated with the place where Type 04 tile is used. Main drawing room, exterior walls of the main courtyard. It is also used together with type 01 tile on the covered porch on the ground floor of the eastern façade.

The whole ensemble of the mansion has a very striking visual effect on the visitor especially due to its surroundings: on the opposite corner there is a communist-era tower of little formal interest, and its adjacent buildings are all very similar and repetitive. This part of the Hongkou district has been intentionally left less modernized as all the mansions on Duoluon Road have been conserved and gradually rehabilitated in order to give local tourism a taste of the city's history. Despite this, there is unfortunately no plaque adequately honouring the neighbourhood's history. A plaque marking the residence of the Minister of the Kuonmitang H. H. Kong has been removed in order to update the information.

2. "RAMOS" APARTMENT BUILDING (1923-1924)

This project was carried out at the same time as Ramos' summer mansion also located on the North Sichuan Road Street. It was originally an apartment building with ground floor commercial space used mainly for social clubs and shops. The building was originally divided into four stairwells, with two

apartments per floor each. The fourth stairwell furthest to the right of the picture, next to the grounds of the mansion, is a half-floor and consequently has only one apartment per floor, although in the original plans it had two apartments like the others. There were therefore 32 apartments according to the plan, but then only 28 were built. Each apartment had a living room opening to the main façade, two rooms opening to an inner patio (very rare in Shanghai in the twenties), a dining room, a kitchen with a room for domestic service, and a single complete bathroom with bathtub, toilet and sink. They have a secondary entrance through the kitchen, which is accessed by the emergency stairway for the residents. Both the living room and the dining room have chimneys. The ground floor apartments do not have a front living room as this space is ceded to the shops. The most notable feature of this building is the introduction of the inner patio in the distribution of its storeys, an element so common in Spanish architecture but virtually unknown in China and which therefore makes it stand out on an architectural and constructive level. In China, the room shapes of high-rise residential buildings are usually designed with many corners which are reflected in stepped façades so that all rooms receive natural lighting, according to Feng shui guidelines, though inner patios which would provide lighting and airflow to the interior of the dwellings are not common. According to the building's recovered plans, it was built entirely with reinforced concrete, using isolated footing with four small piles at the bottom to enhance the grip on the terrain. The plan shows the distribution of pillars and beams, as well as the unidirectional elements of the formwork. They are all made out of a wooden platform on the in situ concrete slabs being formed by bidirectional configuration.

The composition of the elevations is classical, consisting of a base part formed by the ground floor shops openings and the original shapes generated by the still original hallway entrance

Figure 6. Ramos Apartment Building (front view) circa 1930. Source: (Leonardo Pérez 2019 a).

to the apartments, the shaft of the façade would be the wide-span lintels, with individual rectangular lintels which stand out over the rest of the decor outside of the drawing room on all the storeys. In this middle part of the façade composition, the most decorated areas are the stairwells: each window of the staircase for each floor displays a different style. The first of the windows is circular and is decorated with a large moulding.

The windows of the next floor are all square, as are those of the third floor though the latter are crowned by a glass semicircle, on the outside, both are in joint composition joined by another larger blinded semicircle. Finally, in the composition of the façade, there is a large stone balustrade and a series of gables crowning the stairwells, under which is a Greek-inspired ledge that linearly crowns that main façade. This sort of crowning was common in his neoclassical works, and therefore through their study we might be able to better determine the authorship of other works in the city that remain anonymous.

The apartment block that is preserved to this day at 2081-2093 North Sichuan Road is called "Ramos Apartments" and was composed of a ground floor plus four stories, with a later added last floor on the top of the building consequently having the premise as of today of 35 apartments. All the original elements of the top were eliminated when

the floor was added to the building. The current maintenance of the façade and the stairwell is the minimum to preserve the main elements of the shaft of the façade. The state of the original carved wood railing of the main staircase is remarkable, as is as the the woodwork of the exterior windows of the stairwells. Many of the windows of the apartments are also original, as are the steel railings of all the outside balconies.

Unlike the previous work, its relationship with its neighbourhood is more of mimicry, as its height and volume do not greatly differ from other buildings of this part of the city. Most buildings around it are of similar dimensions, and since the section of the street is wide, it does not seem enclosed by the adjacent buildings nor drowned by its neighbours, unlike what occurs to old buildings in other parts of this city.

3. OLYMPIC CINEMA (1914) (LATER NAMED EMBASSY)

Figure 7. Olympic Cinema (front view) circa 1930. Source: (ACE 2020).

Antonio Ramos' second movie theatre in the city but first new build project, was located on one of the most important streets of the "International Settlement", specifically on 127 Bubbling Well Road -now West Nanjing Road. It was the most successful of all theatres of the "Ramos Amusement Co." not only because of the quality of the films projected there, but also because the audience was made up of the foreign upper class of the city. The "Olympic" was inaugurated in June 1914 and later in the thirties it was renamed "Embassy". There are many references to it, but I wish to draw attention to the article written regarding its construction in La Vanguardia Española (1949, p.4) under the amusing title "Un Rinconcito Español" (A little Corner of Spain), of May 6, of which an extract is reproduced below.

> […] Ramos and three of his collaborators entered the enclosure: the architect Abelardo Lafuente, who designed the plans and directed the construction of the Olympic and the Victoria, and the Martís, father and son, great artists who decorated the buildings […] An architect of great value and who knows his worth, after proving himself in the Philippines, Lafuente moved to Shanghai to make his mark, in a place where everything was unfavourable, where there were already architects from many countries, most of them English, who counted on the strong support of their government and their fellow countrymen. […].

In the various historical photos found we observe how the façade shows some influence of the works of Juan de Villanueva in Spain, as well as the first theatre that was built in Spain in 1820, the Vitoria Theatre.

As Silvestre Pérez did in the Vitoria Theatre, Lafuente's "Olympic" is monumentalized thanks to its block structure and the flatness of its façade, accentuated in the center with two Corinthian columns placed in-antis above

the glass canopy, supporting a powerful and cushioned entablature, although it is not entirely visible. The intercolumnium houses on the lower part of the canopy three indented apertures in the central body and smooth parament on the sides to place the film posters at street level. That central body at the top has three small windows decorated with steel fences above the canopy, forming the compositive precedent of the large balcony finished by three thermal windows. This central piece, similarly, to Juan Villanueva's most representative works, eliminates the front as a finish, replacing it with a shield with garlands, and a great set of mouldings. The two lateral bodies are made up of a single thermal window of a much larger scale than those three of the central body described before. In what would be the spandrels of the side windows, the architect places clypes with an indistinguishable decoration. Finally, both bodies at the top have a balustrade finish.

The building plans were solved in a more organic and free manner than on the façade, employing curves both in the shape of the amphitheatre and the side boxes, something that had been already advanced by Benito Bails in his treatises in Spain. According to several press articles, both this and many other venues were at the time all made of wood, and so after several destructive fires, smoking was quickly banned inside all the city's cinemas.

Figure 8. Olympic Cinema (interior view) circa 1930. Source: (Leonardo Pérez 2019 a)

The only existing image of the interior has been found in the original personal portfolio of the architect, and shows us a profusely decorated auditorium with half-point arches with decorative motifs that brings to mind a neo Arabic style, and the pillars' shafts painted in a dark tone with the arches in white. A large wrought-iron lamp presided over the entire space, another material that he would repeatedly use throughout his work.

In his outstanding professional career, Lafuente had a very close relationship with the city's entertainment business. In addition to working on the aforementioned venues, he designed most of the dance halls for the most important hotel company in Asia, "The Hong Kong and Shanghai Hotels Limited". Ballrooms such as the one in the "Astor House Hotel" and the largest and most imposing of all in the "Majestic Hotel" brought him such fame and recognition that even Hollywood called at his door, reason why he opened a professional studio in Los Angeles in 1927. He also worked on the interior renovations of more of the company's hotels, such as the "Palace Hotel" or the "Kalee Hotel" both in Shanghai. Lafuente oversaw the renovations at the "Repulse Bay Hotel" and the "Peninsula Hotel" in Hong Kong, as well as at the "Victoria Hotel" in Canton (Shameen).

Unfortunately, the "Olympic" was demolished in the late eighties to make way for yet another high-rise office tower. The only noteworthy element within the city plan is the new building´s concave form, evoking the theatre that once occupied the plot. Therefore this example of a type of architecture more in accordance with what was being produced in Spain in the 19th century has been forever lost because of its economically strategic location, in a part of the city where few historical buildings were not protected in time from real estate speculation, a fate which the sites on the Bund escaped. This foreign architectural ensemble is now confronted with the spectacular, modern and iconic image of Shanghai's most representative skyline which

originated from the urban development of the Pudong financial district in the nineties to the present day, also responsible for transforming the city of Shanghai into a global financial hub. Therefore, through this review of the three works made by Lafuente for his countryman and patron on the other side of the world, we can see the three most common ways that the old meets the new in the city of Shanghai and in China. Also, it should be noted that although from a Spanish point of view, it may seem that this developmentalism destroys all trace of the past, Shanghai is actually the city in China with the greatest number of preserved historical foreign buildings. There is an increasing awareness on behalf of the authorities who slowly begin to realize the importance of knowing about the past and conserving works that are truly worthy of such conservation and rehabilitation.

We could therefore conclude that in the rapidly evolving urbanism that China is experimenting, the chances of the old to survive are very slim, as proven by the third of the works analysed. The odds improve if the sites are not in affluent districts or ones attractive to real estate speculation as might be the case of Jingan, Huangpu, Luwan or Zhabei. By contrast, in other districts which are more committed to their history such as Xuhui or Hongkou and follow a more conservationist attitude in their architecture, survival can occur thanks to one of two different strategies: "mimicry" with the environment or "singularity" in the environment. It seems as though buildings that survive in Shanghai thanks to the second strategy are rather small-scale, and those that fit into the first strategy are usually residential and were therefore quickly inhabited by Chinese families, with no option to demolish them because it was necessary to shelter a very large population. Nevertheless the lack of training in Chinese architectural professionals in the conservation of cultural heritage in China is striking, as well as the absence of appropriate techniques for them to carry out the type of work meriting the relevant heritage that is still standing in China and Shanghai. Aesthetic and historical training on this type of construction has been almost non-existing until recently, and therefore the ways in which these buildings are "conserved" and "rehabilitated" remain in most cases "dramatic", as they have suffered almost irreparable damage, although there is room for hope in a near future, and it is therefore very necessary to let it be known. Hope should always remain, if not all these forgotten imprints from hundred years ago would never been uncovered by one person only having a first feeling in Shanghai. To become something bigger as it is nowadays it has to be supported by all the unpublished original photos, letters and newspapers luckily kept by the architect's family hope in Madrid. Note that only one of these six photos come from a public archive while the rest are from a private one.

For this reason I would like to thank the Lafuente family for their never ending support to this researcher to be able to uncover the trully remarkable story of their grandfather in China.

PAPER #3.20

TRANSFORMATION OF A HISTORICAL AREA IN ELCHE THROUGH AN APPARENTLY INVISIBLE ARCHITECTURE

Antonio Maciá Mateu[a], Ana Mora Vitoria[b]
[a]University of Alicante, Alicante, Spain
[b]WOHArchitects, Elche, Spain

ABSTRACT

The place where the project is located has extraordinary urban conditions due to relevance of the buildings allocated in its surroundings: the Basilica of Santa María (s. XVIII), a tower which once was part of the Arabian city wall and the Park of the City of Elche (World Heritage).
When we started to work on the proposal, we asked ourselves some questions: how to act in an environment with such historical background? Should our intervention be expressed in contemporary, mimetic terms...? Do we choose, then, an architecture with or without tectonic presence?
Our main goal was, from the very beginning, to regenerate this residual area located in such an emblematic spot of the city. In order to so, we decided to design an invisible architecture that wouldn't compete with its old neighbors, and also to focus on the new vertical garden as the main architectural item of our intervention. Therefore, we built a quasi-vertical garden which hides, in its thicknes, the construction of the cafeteria, the restrooms and a storage room, leaving empty the rest of the square, ready for the terrace to appear.
The garden is a tile of 105 m^2 made up of over 3000 different Mediterranean plants, some of them endemic and singular: Mirto, Hipérico, Lavanda, Carex, Tubalgha, Pennisetum or Lampranto are few of them. Thanks to its hydroponic irrigation system and the mentioned selection of plants, the use of pesticides is not required for its maintenance, what fosters natural pollination. It should be pointed out that this green wall is able to create oxygen for over 100 people, it can catch 70 tons of gases, more than 26 kilos of heavy metals and almost 14 kilos of dust in a year.

KEYWORDS

Historical environment; green city; green architecture; sustainability.

INTRODUCTION

This project starts from the need to make a vertical garden coexist with a cafeteria building in a complex urban space, since it is defined by two of the historic buildings in the city of Elche: the Basilica of Santa María and the architectural complex of "La Calahorra", all this, in the area of the Santa Isabel square. The proposal aims to merge the two needs into a single action. A vertical garden is projected and built that acquires volume to be able to house the cafeteria building inside and, therefore, acquiring the status of "invisible building". In actions of this type, it seems important to bear in mind two aspects from the beginning, on the one hand, the impact that a new construction causes in the historical surroundings of the cities, and on the other, the condition of the use of vegetation as part of the project and the positive consequences it means for the air in these environments. The use of prefabrication processes complete the developed proposal.

1. STARTING DATA, BACKGROUND AND HISTORICAL ENVIRONMENT

In 2013, the Elche City Council published a list of 35 urban spaces in the city that could be transformed through the construction of kiosks or cafeterias, calling a competition for each of them. Space number 25, square of Santa Isabel, turned out to be one of the most interesting. It is an urban space, 140 m^2, finished on sand and delimited by a party wall belonging to a 19th century house. This square enjoys a privileged location, because in its immediate surroundings we find great samples of the city's heritage: the Basilica of Santa María (18th century), a tower-entrance belonging to the Arab wall of the city (12th century), the Altamira Palace (original from the 15th century), the municipal park of Elche (World Heritage) and the remains of the old 12th century Arab palace known as "the governor's house".

For this space, the competition asked for the design of a 20 m^2 built cafeteria, a terrace that covered the earth floor and a vertical garden on the party wall.

At the beginning of the proposal we asked ourselves the following questions: how to act in an environment with such historical baggage? Should our intervention be expressed in contemporary, mimetic terms ...? (Mikhaïl 1992) So, do we opt for an architecture with or without a tectonic presence? (Castrillo, 2011).

The proposal opts for an invisible construction that does not compete with its neighbors of past centuries and that puts the vertical garden in the foreground of the intervention. Thus, the project ends up becoming an almost vertical garden, a garden with volume that houses the dry construction of the cafeteria, the toilets, a warehouse and the rest is terrace.

1.1. Basílica of Santa María. sXVIII

The first of the buildings that define the performance environment is the Minor Basilica of Santa María. It is located in the historic center of Elche, within the old walled area from the Arab period and in front of the tower that marked the entrance to the city from the northeast towards Alicante. The basilica is located on top of a previous church that, in turn, was built over a mosque and is one of the first baroque buildings in the diocese of Orihuela. "The church is the scene of the representation of the "Festa or Misteri d'Elx" every August 14 and 15, uninterruptedly since the 15th century. For many authors, this

Figure 1. Basílica of Santa María (WOHArchitecure 2014)

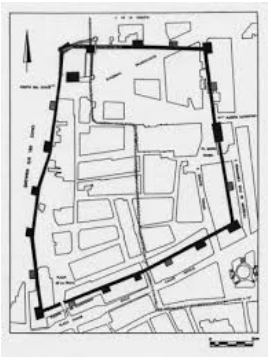

Figure 2. Medieval wall (López Seguí 2004)

purpose is what influenced their spatial and stylistic conception. " (Guía de arquitectura de la provincia de Alicante 1999)
The basilica has a "Latin cross" plan, with four chapels on the sides of the nave, transept and ambulatory behind the presbytery. The arms of the cross are covered with semicircular vaults and the transept with a grandiose dome that every year makes a heaven (a baroque sky) for the "Misteri", hiding the aerial section. The exterior is forceful, with large smooth cloths that contrast with the reliefs on the covers. Both the dome and the large, bare and forceful cloths, that define the ambulatory are visible from the project's area of operation and make up part of the Santa Isabel square.

1.2. Arab wall (s.XII) and the interventions of centuries XV and XIX

The second of the buildings, which marks the environment of the performance and condition is the main tower of the medieval wall. "After numerous reforms, today there are only the remains of what was the main tower of the town's medieval wall. It is a prismatic tower with a rectangular ground plan, with the base walls stunted; the factory is made of masonry covered with mortar, with stone ashlars at the base and at the corners. The neo-Arab windows with the arches in the line of the change of plane and the semi-open vertical booklet blinds. Both these elements and the castellated brick finish are from the 19th century. The semi-detached manor house outside the walls must have taken advantage of the villa's starch. It consists of a basement and two floors and the windows and the portal are a good example of the noble architecture of the XV-XVI s ". (Guía de arquitectura de la provincia de Alicante 1999). On the wall, houses were built that have disappeared over time to the point where there is only one from the s. XIX. Next to this house, another residential building was erected, which was demolished at the end of the 20th century. The party wall of the house attached to the tower and the site left by the demolished house form the basis of the action, since the cafeteria and vertical garden were built on the party wall and the terrace was placed on the site as an extension of the Santa Isabel square.

Figure 3. Tower of Calahorra (Municipal Archive of Elche 2016)

1.3. The urban environment in the centuries XX and XXI. Santa Isabel square

The Plaza de Santa Isabel is the annex to the performance area and is delimited by the Basilica of Santa María, "La Calahorra" and buildings from the 20th century. In 2004 and as a consequence of the pedestrianization of the area, a series of archaeological excavations were carried out. As a consequence of these excavations, the discovery of the remains of a 12th century Mozarabic palace that was called the Governor's House occurred. (Amorós Fructuoso 2005). In the Amorós and Fructuoso project, the floor of the old palace was built using travertine marble blocks. The square connects with three of the most representative areas of the city of Elche: the Eucharistic Congress square, the Glorieta square and the Municipal Park

Figure 4. Santa Isabel square (WOHArchitecure 2014)

2. PROPOSAL FOR INTERVENTION IN THE HISTORICAL CENTRE

As explained in point 1.0, once the scope of the action has been chosen and bearing in mind the urban and historical environment where the proposal is developed, the question arises whether it should be an intervention that clearly shows a contemporary construction or not. (Heath 1996). In any case, how to intervene? With an exposed piece? Through architectural mimesis? or acting with an invisible architecture or which one of the most significant materials prevails in this beginning of the XXI century: vegetation. (Abel 2010)
Initially, several intervention proposals were made, but only two were developed and one of them was built. The first one was made up of three elements: a constructed piece of 20 m^2, a 100% vertical garden (Xin xin 2011) and a terrace for tables. The second of them continue the same three pieces but developed differently. The 20 m^2 building is hidden under the garden, which becomes an almost vertical garden. The terrace occupies almost the entire performance area.

2.1. Exempt Building

The first of the proposals consisted of designing an architectural piece of 20 m^2 of extreme lightness that allowed showing the power of structural actions typical of the s. XXI. For this proposal, the projects of the Japanese architect Junya Ishigami were studied together with Jun Sato's laboratory for the 2008 Venice Biennale and the KAIT workshop building for the University of Tokyo. (Ishigami 2018)
The architectural piece was solved through the use of two parallel ring-shaped porticos 8 m long by 2.60 m high and separated by 2.30 m. These porticos were designed as preflected structures in the same way as those proposed by J. Ishigami and J. Sato (Sato 2020). In the design of the porticos, a 56 mm counter-arrow in the central part was considered. This structure was tensioned with a 12 mm diameter steel bar until it recovered 80% of the counter-arrow. The structure proposed, thus, is extremely light since it resolved an 8m light with only a structural tube of 100.60.8. In the thickness of 100 mm all the facades and roof were resolved. The proposed materials, in addition to structural steel, were aluminum and glass.
The piece houses the part of the program related to the cafeteria and was placed in the square formed by the site of the old residential building of the s. XX that existed next to the old wall. The cafeteria was separated 3 m from the party wall of the s. XIX built next to the "Calahorra". In this party wall, the construction of a 100% vertical garden was

proposed (Pérez-Urrestarazu 2015). The rest of the plaza was intended to house the outside terrace of the cafeteria occupied by tables.
This first proposal presented the alternative of showing a small building that represented contemporary technologies and materiality. The concern to contribute to the improvement of the air conditions of the immediate environment of the area of action was also shown. Therefore, it showed two of the contemporary concerns of architecture: technology and the relationship between human beings and nature.

only show the new architecture through the vegetation. Try to show the relationship between contemporary architecture and concern for the environment and, therefore, show how architecture can contribute to it.
In this new proposal only an almost vertical garden is shown that, which houses the construction of the cafeteria inside and that leaves, almost 100% free, the performance plot that is intended for the expansion of the Santa Isabel square and that houses the tables that form the terrace of the cafeteria. It is important to highlight how an almost invisible performance allows

Figure 5. Proposal1. Exempt building (WOHArchitecure 2014)

2.2. Integrated building

The second of the proposals studied maintains the essential concerns and premises of the first one, but applied with another approach. In the first, it was shown how the proposed construction "competed" with the historical constructions of the environment. Perhaps , this first alternative was too pretentious and its modification allowed to develop the second alternative. In this new proposal, the built architecture is hidden behind a green cloak. The decision is clear: to value historical architecture and transforming an urban area. The initial site showed a somewhat abandoned area with an unmarked party wall and which, over the years, had become a "pipican". The result was not in accordance with the historical and architectural importance of the environment.
The union of the intervention area with the Santa Isabel square allows a clearly recognizable urban link to be established that highlights the historical constructions that define it, in addition to serving as a connection to the important urban points of the city: Eucharistic Congress square, the Municipal Park and the Glorieta square.

Figure 6. Proposal 2. Integrated building (WOHArchitecure 2014)

3. THE IMPORTANCE OF VEGETATION IN THE PROJECT AND ITS IMPACT ON THE NEAR URBAN ENVIRONMENT

The vegetation and the architecture have always been in contact but with more intensity today due to their quality to interact and purify the air in the environment where it is placed and to be able to create microclimates. (Ochoa de la Torre 2012)

Vegetation is also important for the role it plays in shaping and environmental quality of open spaces. It is useful as a humidifier and purifier of the environment. A tree-lined street is four times less dusty than a non-wooded one, and 150 m^2 of leaves or 15 m^2 of grass produce enough oxygen for ten people. " (Díaz 2005)

The data presented above gives an idea of the importance of the use of vegetation in the air quality of cities. Fortunately, the city of Elche is the fifth city in Spain in the ratio of m^2 of vegetation per inhabitant.

3.1. Effect on the city environment

The almost vertical garden has a surface of 105 m^2 and composes a vertical mosaic consisting of more than 3.000 Mediterranean plants, some endemic and unique, of high botanical value. Among all of them, it is worth mentioning the Myrtle, Hypericum, Lavender, Carex, Tulbalghia, Pennisetum or Lampranto. Thanks to its hydroponic system and said selection of species, the use of plant protection products is not necessary for its maintenance, which favors the natural action of pollinators.

The garden was completed in 2014 and after six months and after measurements made, this garden allows the following annual parameters to be achieved:

- generates the necessary oxygen for more than 100 people.
- obsorbs 70 tons of gases,
- removes 26 kg of heavy metals and traps 14 kilos of dust. (Solano 2014)

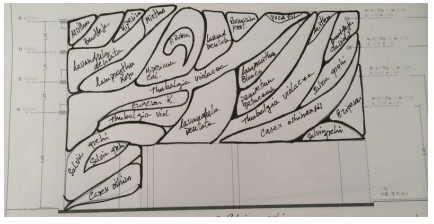

Figure 7. Plant species map (Solano 2014)

4. TECHNICAL DEVELOPMENT OF THE PROPOSAL

The technical development proposal of the intervention is divided into three parts: the base structure that forms the garden, the construction of the cafeteria container and the platform that forms the terrace.

4.1. The almost vertical garden structure

For the construction of the garden, a triangulated structure was designed, attached to the partition consisting of square steel profiles. This structure is vertically attached to the masonry party wall and is supported on the foundation in order to define an interior space to house the prefabricated construction of the cafeteria and the rest of the garden facilities.
The garden base is made up of two layers, one of 10mm PVC bolted to the metal frame and the other made of a double layer of felt. Between the two layers of felt is placed the irrigation system formed by a 1 ″ PVC tube that soaks the felts (Solano 2014). The outer felt layer is trimmed and stapled to the PVC to form a container to place the plants.
The structural and cladding package described allows giving enough volume to the garden to be able to house the construction of the cafeteria, the toilets, the warehouse and the facilities.

4.2. Floor plan and structural volumetry

The container that houses the cafeteria program is intended as a prefabricated construction. Within the volume defined by the structure and envelope, described in the previous point, all the facilities that the garden needs are introduced: nutrient dispensers, filters, control of the PH of the irrigation water, water tanks and the cafeteria container. This piece is presented, at a constructive level, as if it was just another deposit for the garden installation and is made of fiberglass and resin. The construction of this container was carried out in a carpentry workshop and is made up of a 5x5 cm pine wood skeleton and 19 mm high-density MDF boards. All this structure is covered with fiberglass and resin in the same way that they build the water tanks that the installation of the garden requires (Keller 2008). The piece was built in three parts to facilitate its transportation and assembly on site and was placed on a reinforced concrete foundation base.
The built piece, thus, contains the storage, facilities and service areas of the cafeteria, as well, as the bathrooms.

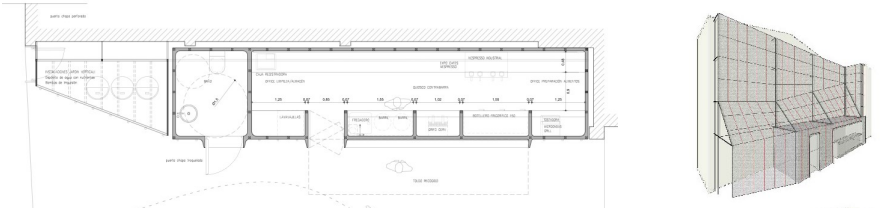

Figure 8. Floor plan and structural volumetry (WOHArchitecure 2014)

4.3. The terrace platform

The platform that forms the terrace is defined by an 8x8 cm pine wood substructure on which a series of 12x2 cm green lacquered pine wood boards are placed. This platform contributes to the expansion of the Plaza de Santa Isabel in a staggered way due to the unevenness between the sides of the terrace.

CONCLUSION

The situation raised in this intervention and its development, allow us to draw three conclusions clearly and concretely:

1. The best way to intervene in an urban environment defined by a historical architecture is not always to display or show a construction that competes with the existing ones. It seems sensible on this occasion to be able to act and solve a program by hiding the construction and not altering the built historical environment. (Loew 1998)

2. The importance of the use of vegetation in architecture and in cities as a means, on the one hand, of showing the intentions and commitments of contemporary architecture with the environment and, on the other hand, of showing the commitment to people's health that we live in cities.

3. The importance of the constructions that plan the processes of manufacture and industrialization of architecture. For more than a century that incorporated this approach and proceed in the field of Architecture. This approach has, today, much more power given the rapid advance of the technology that we live.

PAPER #3.21

RECUPERATION OF THE STAIRCASE SPACE OF ARMA CHRISTI SAN JERÓNIMO OF COTALBA

José Manuel Barrera Puigdollers[a]
[a]Universitat Politècnica de València, Valencia, Spain

ABSTRACT

In the structural consolidation works of the body of the Arma Christi staircase of the Monument of San Jerónimo of Cotalba, authorized by the regional Ministry, previous works are carried out on debris, removal of partitions and test pits that allow for the locating of various elements and substructures that were not previously identified. These consist of a relevant heritage and historical value in recognizing the evolution of the monument. Given the relevance of what was found, the intervention is conditioned: the most significant element to introduce, the recovery of the internal staircase to access the Renaissance doorway, the Arma Christi attributed to those who followed on from Pere Compte which was initially proposed as a mere element of use, must now adjust to the relevance of what was found and with this, adapt the intervention criteria to the narrative of the space and its discovered values. Therefore, moving from the action of mere wall and structural recovery over an era, to the recovery of a space with historical heterogeneity, requiring as a response the introduction of a staircase that dialogues with this sequence, at the same time that the historical succession itself is displayed. Moving therefore from a functional to temporary element. This allows diverse time-memory and time-semiotic devices to be used, which activate meaning and even the emergence of the interpreting invention.

KEYWORDS

Intervention; heritage; temporary devices; structure; semiotic.

INTRODUCTION

In the works followed by "Structural reinforcement of the Arma Christi staircase", significant heritage elements have been uncovered[1]. Given the relevance of what was found, the intervention is conditioned: the most significant element to introduce, the recovery of the interior staircase of this disappeared space must adjust to the relevance of what was found. Its objective: the design should adapt its original material-formal criteria of the planned intervention, taking on a more diverse role displaying all of the present space-time; turning into an *element of temporary activation or temporary device* instead of assigning its design to a unique or neutral abstract temporary-space representation. Additionally, this area has undergone various alterations over time and present serious pathologies, making the north and east façades to progressively detach, dragging the structure of the monastery (Alonso 1988). Therefore, the design works of the new stairwell, are treated as a temporary device, are conditioned simultaneously to the structural.

[1] *Through resolution published in the DOGV no. 8361 of August 14th, 2018, aid is granted by Conselleria, Dirección General de Cultura y Patrimonio, to intervene in the stairwell space of the northeast corner of the BIC- Monument, San Jerónimo de Cotalba. By Decree of the Mayor's Office of the City Council of Alfauir, no. 223/2018 of October 11th, the intervention is authorized.*

Behind it, the partition on the flamboyant railing. Source: photographs by the author.

1. HERITAGE FINDINGS IN THE PREVIOUS ARCHAEOLOGICAL WORKS

The appearance of the unknown original heritage elements alters the initial estimate on the value and character of this space (Arciniega 1999), requiring it to be part of the guided visits. These elements that change the marks of the intervention and design of the staircase are the following:

Behind the off-center frame facing the wall of the north façade, concealed an original Gothic opening with superior rosettes in perfect condition, small pillars that defined some tambours that have partially arrived and are carved in stone. The opening had been walled up in a previous period, with a smaller niche in the middle, perhaps to prepare for an image. Due to its offset from the axis, its size and finish, it would correspond to a definition that considered an upper reading, since it is centered with this section that reaches the first floor (Barrera 2015).

Discovered on the ground floor, at the spring of the staircase was a stone embedded in the ground, of stone tap or limestone equivalent, similar to those originally used as a carving stone, smaller than the existing hole. This makes us think that the original 1388 staircase was carved in this stone at least at its spring, and was narrower than the current opening without completely occupying it, and due to its size, very likely simpler than the renovated one next to the 1st floor door and cloister promoted by María Enriquez. It was this intervention of 1505 that altered its longest-running configuration, taking advantage of the entire perimeter of the current stairwell, leaving marks of the carved handrail on the perimeter wall. From this, we only found three steps of the landing built into the width of the 120 cm wall.

The uncovered gap of the main façade, due to its typology of lowered segmental arch, corresponds to the Gothic base, built before 1485, when it was acquired by the Borja family. The carving motifs are floral, grape leaves, verifying this period.

We uncovered two overlapping staircases ascending from the floor level to the upper floors of the cells, attached to the side wall to the east, that is partially emptied in order for it to be built-in. It was developed in only one flight with a compensating curved spring. The lower staircase is the original one. It is fairly simple in design with a clay tread and riser. Once the overlap has been eliminated, leaving the side of the wall where it supported the identifying marks for its explanation, we found the original ascending one in perfect condition and we understand the problems that led to the two overlaps. When reaching the landing at the end, there is a lower altar and two entrances: to the right through three steps you access the corridor elevated in 1630, originally Cambras. The left it is accessed through three steps, now only two since one is missing that would invade the landing (the reason for its new layout), the access step to the landing of the laundry rooms (under the current roofs of the northern cloister wing). Following its layout, ascending two more overlapping but unequal sections, up to the upper floor of cells, 4th level raised in the 18th century. This floor was raised between 1739 and 1759; some works were delayed until 1828 where there are still small finishing actions, after a brief period of secularization and abandonment of the convent. At the same time, in 1739, the decision to raise this 4th floor to 70 cm, is recorded, perhaps to make it flush with the height of the church. We say that the sections are not identical. While the first one adheres to the smaller stairwell over half of the east vault of the space of the staircase which no longer existents, the upper stairwell that accesses the 4th floor is made bigger occupying the space between the north walls and its inner parallel. The reason for this duality is to leave a corridor behind the first section of the staircase for another direct access from the 3rd cell corridor to the clotheslines and laundry rooms, the space under the northern roof. Dual access solution to the same space that was solved by dividing the direct accesses from the staircase that were was found later, leaving only the access through the rear hallway.

We discovered that the support systems and stabilization of the overlap of the ascending stairwell to the upper floors were not as we expected. Through the drawings made and the previous data collection, the graphic results give us a glimpse of the possibility that the staircase with two overlapping sections that saves the height of the 3rd to 4th floor, was supported by a relieving arch that arranged north-south supporting this and will transfer its weight to the two parallel walls, 120 cm thick. However, disassembling this overlapping flight of stairs and verifying the existence of another original below blur this reasonable hypothesis. The reality is that the described northern landing, which has two entrances, a cell corridor next to the north façade and laundry rooms next to its north façade, rests directly on the lower vault, in its northeast quarter. The rest of the sections and the perimeter staircase are supported on sand, pieces of rubble and straw which provide a filling on the lower vault, the southeast quarter, since only half of the right vault is conditioned by this load. This defines a very risky layout and gives rise to the relevant identifiable cracks. It also accounts for vertical cracks due to offsetting, torsion and loss of verticality of the guide wall for the stairs.

We uncovered a handrail –a lookout over the staircase opening, with quality flamboyant latticework, dated around the same time as the flamboyant staircase of the old refectory, today the *Virgen de la Salud* Chapel, as the closing of the Arma Christi portal over the stairwell space. It is accompanied by a circular pillar with a capital similar to the one on the portal, from the same era and authorship with a tambour base perfectly synchronized with original ascending steps of the Arma

Christi portal. This indicates its simultaneous execution, around 1505-1510. This balcony is designed inside the stairwell on the outside, 40 cm of overhang on the design of the 120 cm lower wall. But we observe that this capitel did not originally reach the ribs of the current vault, but a composition that was added later. Originally it was a mullion of the bent entrance of an equivalent rail lengthways that would give access to the priory cell. The surfaces found under the side staircase and the remains of the edge vault under landing confirm it.

Design of the ascending staircase: the entire ascending staircase is arranged around an "espina" that between the ground floor and 1st floor forms the right support of the vault and its stairwell envelope, its thickness being only 15cm. It is arranged roughly on the axis of the right arcade of the portal. To arrange the ascending section, it is necessary to gain space in the lateral wall, which is the inner wall of the cloister, east ambulatory, which continues north. To make this happen, it must be emptied, reducing from 120 cm in the cloister to 50 cm; that is, taking away 70 cm, to arrange the only ascending section. This reduced stonework is the one that separates from the old priory cell arranged on the old ante refectory kitchen in the extreme northeast. Today, this wall coincides with a lower diaphragm arch in PB over the silos, of the same thickness. But it can be seen shaped by the emptying of an older thicker wall, by certain signs: on the north wall and in the uncovered underground corridor. Thus the ascending section from 2nd to 3rd level is encased in a 15 cm guide wall and a 50 cm wall. In the section from 3rd to 4th level, the 50 cm wall is made up of two 10 cm hollow sheets filled with rubble, where the ascending staircase vault supports on the inside and is built into the outside, gaining thickness in its upper flight. This effect is worsened on the 4th floor where this wall becomes 15 cm again, when the interior facade-closing wall is 60 cm. That is, reducing its width considerably and losing bearing capacity. As a result, it is necessary to replace and strap it so it can work correctly in its elevation. On the other hand, the left guide wall of that one-flight staircase, continues vertically, incorporating a staircase eye partitioned to the left, in the form of a cantilever, which forces the collapse in its width due to the lack of rigidity and excess weight in that direction. Both circumstances justify the level of breakage, torsion and collapse of this staircase, which requires strapping and bending to give it mechanical capacity.

The ascending staircase is poor in material nature and is resolved with ordinary partitioned vaults, which are in line with a time when these professions were certainly daring. Its layout was most likely redone in the 18th century, when the decision was made to raise the floor and thus giving an adequate route, from 1759.

Figure 2. Images of the heritage elements found and cleaned. Source: photographs by the author.

The lack of resources at that time would justify its finishes: It has a partitioned exterior space on the upper floor, with a semicircular upper arch, but without lateral finishes. The general partitioning of the opening of the convent is in line with the period of secularization, to avoid intrusions. The upper opening must never have been opened, since in its center there is an original battlement that has been left as a test pit, wider than the closure of the rest of the opening with which it is integrated. It must have had this lightweight configuration to reduce weight and emerge in a simple way as a staircase above the northern ambulatory roof.

The guide wall that we describe is not vertically aligned on the design of the left diaphragm arch of the stairwell, but projects into the gap, 40 cm, like the flamboyant square viewpoint. Given its vertical development and the weight it supports, has facilitated its breakage. This effect is carried out on the support plane of the flat slab on the lower vault by sticking out brick by brick, about 3cm, which are then refined making a curved cup or cantilever. This is divided in a third of the north interior façade, with a displacement of 4 cm towards the staircase. Which requires urgent repair.

2. CONCEPTUAL CRITERIA APPROACHES TO THE STAIRCASE

Initially, a vaulted staircase was anticipated that recovered the original construction system, which allowed the internal and external parallel walls of this body to be braced. The state of the interior substance and the localized remains were less relevant and we did not know if their state would be finally recognized. For this reason, the staircase was functional and not relevant from a heritage perspective; that is, it did not have an impact on the authentic values. However, the previously outlined description and the findings give this space a much greater importance due to the accumulation of the remains of different space-time, whose appreciation will allow to tell its own evolution. Given this relevance and following the consolidated patrimonial discourse in these types of actions, any trace of a phase or style of construction accumulated in the extensive history of the monastery should be highlighted in its value and made known. Fortunately, there are no dualities that require declarations on one phase or another, except for the 1759 staircase that was overlapped onto the previous one from 1630, on a lookout with a railing dating 1505. Proven that the second is

Figure 3. In the first image we see the problem in the outline the upper vault of the stair space whose edges do not coincide at the vertices. The second and third images show problems of joints and geometry posed by the incorporated mullion, originally the top or square post of the flamboyant L-shaped railing, which is strangely extended to form the start of the added ascending staircase. improper, modifying the encounter with the floor plan where the Arma Christi portal is arranged and verifying that an intervention took place to make this route more comfortable, it was dismantled leaving a mark on its side to describe its existence and its reasons. Thus, the whole body is recovered and returned to its original heritage value. But the staircase to be introduced is a current element that constitutes one more page in its history, that of 2018. From a semiotic perspective, must solve a stairs that contains the following features:

It begins a dialogue with the existing: this dialogue is as equals, without complexes, but without debt. Enough elements have been found to build such a dialogue: the first three steps to arrive at the 1st floor exist, so their tread to riser relationship is established. The height and modality of the railing is engraved on the surrounding walls, and therefore its details, geometries and characteristics are set, but interrupted. The opening of diaphragm arches, where originally there would have been walls reaching its support plane, are cut and interrupt it, with the railing appearing sectioned. There are so many lines that it is irrelevant to continue it, so as not to create conflict, but it is possible to recover its 'significant' elements in the central flight, with its staircase eye following the Gothic tradition of marking the side of the step on the thread of the vault.

The dialogue must be respectful in both directions: this will force its autonomy: different materials, different configurations, not to be touched, not even brush up against it and yet both are necessary. The surround staircase is necessary because it tells the story of its initial layout and demolition. Its changes over time speak of a noble and relevant access, and end to famine, economic needs and the return of the monastery to an agricultural production unit, typical of the 18th century. This is its part of the speech. The recovery with a current response speaks of the return of the routes, of its absence of an agricultural unit in the present day, its cataloging and its consideration as a Monument. It speaks about putting the building in value in its current conditions, regardless of the urgency and needs of another time under the opinion of the friars. It speaks about today, looking back in search of a future.

The meeting of the present and history should be a structure of limits: get close, but do not touch; they are needed, but are avoided; speeches are distributed, like a magnetic interaction. The new staircase will be light in its lateral view, of only the thickness of the step, showing constructive and technical capacity, as represented at the time by advances in stonework and production in 1505. It will have lighting around the perimeter to highlight the historical surround staircase without being able to touch it; at the 5-6 cm joint perimeter is left. But without being seen, hidden and indirect. Climbing the staircase leaves gaps with the diaphragm arches executed a posteriori, by enabling the trullos. These gaps do not have a railing so as not to affect the existing remains of the perimeter but they must have protection against collapsing. This protection will be made with sections of double, tempered glass held like the curtain walls by means of linear support on platen at its base and upper clamp anchored in the diaphragm intrados about two or three cm from its edge. This means approximately 8-9 cm of projection from the edge of the step; projecting the support steel plate marking a light perimeter void. Knowing that the staircase will have 155 cm of step on each side and being projected from the box of the central structure in the form of a cantilever its execution must be by means of sheet metal measuring 1.5 cm and 12 x 31 with a platen in the middle 3 cm for intermediate support of surface finish stone. This requires a hidden support at the outer end. For this

reason, the seal strip in the shape of steps will be made of 1.5 cm and 500 steel. Being exempt, it needs a centered support: in the corridor between trullos there will be a support of H 100, with bracket and fastened bracket, where it supports the cantilever that forms the central railing of the two sections. Actually supported by the two centered beam sections that extend into the plateau. Those beams will be UPN 180, arranged broken, resembling the tread and riser will leave the dark on the intrados of the staircase, with side view when ascending, so that this game of breakage recalls the usual Valencian Gothic layout, in reality resolved, on the contrary, by means of a lateral projection. Such tiered beams will receive a cantilever box projected on both sides, doubling the cantilever effect from the trampoline. The staircase is fastened on the existing brick masonry at two points: under the third step found in a high flight, carved in a wall 120 cm thick, carved for the support of the original vault, and at its spring on the ground floor, where it was previously attached. In this case removing the original stone from its minor spring, to show it. The trampoline beams described are not self-supporting: they need superior latticework, which must be hidden with the thickness of 12 cm of the original rail. As the upper handrail is visible on site, it is reproduced in metal with a diameter of 9.5 cm like the existing one, from where lateral collaborating plates will be welded with the same original cutting, to cover the latticework.

The prominent limitation is then evident: the central parapet on the trampoline supports the corbelled steps. A technical display equivalent to the constructive achievements of the time. It is a tribute to its risky progress, to the skills of Pere Compte and his officer, Genovés, to his contributions to complex balances. This reference is accompanied by the internal emptying that the UPN 180 profile will leave as a shadow on the intermediate ascending parapet, which in turn will be lined with a steel sheet lacquered on the outside to recover its original 12 cm thickness. To intensify this Gothic reference a little more, the meeting of the vertical plate with the UPN profile will be resolved with a 4 x 6 cm structural tube with a thickness of 4 mm, which will resolve the meeting and will leave an additional 2 cm projection, thus conforming the typical but abstract and conceptual pattern of conventional Gothic formalization.

3. THE STAIRCASE AS A TEMPORARY DEVICE

A temporary device is a skein or multi-linear unit made up of lines of different nature that evoke temporary dimensions. These can be shown through adhesions of social, material, phenomenological, aesthetic, psychological, environmental and hermeneutic or memory information (Deleuze 2012; Foucault 1998). Kubler refers to them as condensers of

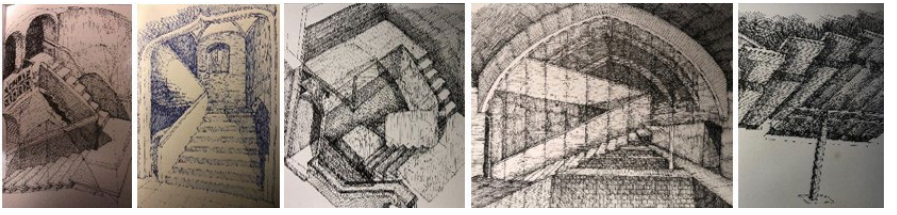

Figure 4. Evolution of the design, the drawing being the support for understanding the scope of the staircase and its implications in allowing to see the time. All temporary devices are derived and graphically tested. Source: drawings by the author.

satisfactory and potentially active states; Buchanan, active agents of longer duration; Calvino, machines for multiplying narratives; and Derrida calls the work that integrates various devices, the producing machine. The representation of time with the intervention takes on a demanding nature, for several reasons: the narration present in the heritage values belong to historical events in time, superimposed; because all time has been relevant in the evolution of the monastery and its appropriation as we now know it; it is linked to a changing social history and because it presents an evolution of the cultural matrix; it is a melting pot of ethnography and history that is part of us. Therefore, expressing their time, in time, through time and generating time is a necessity, without forgetting that from the dialogue between the performance and design, a time yet to come can appear. The floating staircase acts like Denkbilder, "images that think" (Benjamin 2012; Kracauer 2008; Benjamin 2006); like in *Erewhon* by Samuel Butler, this fantasy arises from the negative view of the Darwinian theory, that allows the building of an anti-ethical world, where the concepts are treated as objects of an encounter, endlessly rise up in the successive here and now. Two characters must stand out for this; semiotic time and its display devices and memory time with their own.

3.1. Time and semiotics

- The metonymy part: "the sculpture staircase" for "recuperating the staircase has a structural autonomy". What is shown here is that a mark represents the seed to which it belongs. The "sculpture" mark associated with "structural autonomy" has a certain consistency and veracity. In this way we carry out a displacement of the *structural* through the *sculptural,* making a lateral shift of meaning, although metonymy maintains a certain resistance, because a new meaning is not produced. It is metonymical because a meaning always refers to another meaning or in different way, the meaning does not lie in a single signifier, but in the game between signifiers in the chain, and consequently resulting in this *unstable* operation. "The staircase floats", for "the staircase is inserted into its opening without affecting the test pits and carved remains on the walls from which they nourish to finally understand itself geometrically". Here a seed represents one of the marks. This set is specially forced on its glazed outer perimeter against the Gothic arches, where the lightness that forces the gaze on the central parapet is evident. "Floating sculpture" refers to the weightlessness of certain advances in designs and drawing of high Gothic arches, at the start of the Valencian Renaissance period. It refers to new materials, bold claims, operations of structural risk and assembly that we know. The temporary dimension of this device deals with the recovery of a past by 'its law', not by its form, and its open dialogue with its past characteristics.
- Metaphor: 'Recovery of the lateral enclosures of pointed glass'; 'Recovery of the staircase eye as a bearing wall within the same original cut'; 'Recovery of the size of the staircase in mimetic geometry, but in metallic material discreet in its finish'; 'Recovery of the Gothic geometric lateral cut'; 'Recovery of the extrados of the broken stringer as if it were a Piranesian staircase'. All these elements seek *condensation*, consisting in substituting one meaning for another, creating a new meaning that replaces that one by adopting the meaning of the first. The condensations with the topic are not the same as those achieved with words since it does not break from a common language and therefore, it is always wider and more open.
- Itineraries of the event: the visual route of the staircase, observing the trullos on the right, the exhibition hall, the old winery, on the left, along with the other trullos, is in itself a poetic journey that takes you to a transformed origin. The rescued facade window and the recovered flamboyant railing, take us back to the intended nobility of the predecessor of the Arma Christi portal, María Enríquez, consecutive wife of the

two eldest sons of Pope Borgia. Memories and the passing of time are displayed, as in Ingmar Bergman's cinema, which converge and diverge in a precise place (idyllic garden, junction, corner, here the noble staircase that ascended to original priory cells) to explain the condition of the subject. This condition shows its intimate and psychological interior with the enunciating exteriority (narratives present in the peripheral material recovery). From the symbolism of the exterior, an internal introspection of the subject is carried out. "Retrospective journeys" that reconstruct memory, relating space and time, in both directions. In this, the relationship between the architectural landscape shown and time is crucial (De Lacour 2013, 59). Also presented are some "cinematographic devices" such as:
- Façade window as an object device, which marks the atmospheric hours and relates to the surrounding landscape, weather, times, etc. The phenomenological resources allow giving a concept of time in the act of understanding. But they also transfer the time of its existence, in this multiple case; the recovery was necessary to dismantle three overlapping holes with different openings, until the main one with its capital sculptures is extracted.
- Flamboyant railing on the upper plateau; added in 1505-1510, forming a viewpoint with two sides, of which only one remains, is also as an object device. At that time there was no access to the upper porch from this point, which was introduced in the elevation of cells over the priory in 1630, with partial ruin in 1702-1704, with placement of an octagonal prop on that date. A body that was raised again in 1734. The long side of the original flamboyant parapet served as a corner access balcony to the priory cell over the old kitchen. The intervention of the 1630 (the first elevation of cells) eliminates the long balcony and introduces a staircase, partitioning the recessed side into the hole, but without modifying the upper vault. It is 1734, with the second expansion of cells when this staircase modifies the vault on the staircase, and on this an additional two flights are designed reaching the high cells on the 4th floor. The certainty of this route comes from having found the inner lateral capital of the right portal, buried among the remains of the missing staircase, and therefore in the latest reconstruction actions from 1759 to 1824. Since they were partitioned, they have remained intact. This dialogue between the added staircase (whose lateral marks were kept) and the visible must reveal this temporary sequence. Its understanding is clear, if we have the capital suspended on the wall in its place of origin.
- Other lighting devices: the perimeter light of the staircase arranged in the gap against walls highlights the expressionism of the footprints left by time and the reconstructive transformations of the monks successively: prints, marks, scratches, mortar patches, crevices, cleaned cracks, etc., are expressions of the roughness of the envelope. We show intentions since artificiality contrasts the *natural* lighting of the front hole.
- Evocation devices: materials and added elements, show different times. The same color of the staircase, primed with zinc oxide, leaves a degraded whitish texture like the perimeter, but different: we understand Deleuze (2012) when he describes it as an expressionist gesture of "making a hole". As André Breton does with regard to Chirico's paintings, *Mystery and melancholy in a street*, 1912, "what he does is express feelings that help recognize images in the subconscious, evoking hidden ideas". Here, are the ghosts and fantasies of the interpreting subject that connect with the images recognized in the action of the route and in some visitors it will link with their pareidolia or apophenia. The devices, by forcing situations, radicalize the differences, preventing impossible repetition and highlighting the imaginary illusion.
- Factography: the contribution to the constructivist epic theater contributions by B. Brecht, E. Fuchs and S. Tretiakov, bring different concepts together with Benjamin, within "the dialectic of the state of detention"; the

Figure 5. Digital tests of the staircase, its spaces and relationships, develop it as a temporary device. Source: drawings by author.

aesthetic fusion, the re-functionalization, the active and influential participation that coincide in a sequence of strategies: estrangement, factography, use of attractors, affirmation of authenticity. All within the following process: interruption principle, staging as ideogram, subconscious relationships, discovery of the state of affairs, exhibited value, merchandise, heterotopia or organization of the discursive mass. In this case, the following dualities: the existing and recovered old steps and the new ones; the perimeter railing embedded in the wall and cut; the lateral window facing nothing; the ascending route observing on both sides other agricultural structures forcibly introduced in times of starvation, facing an image of a closed box typical of these structures; lateral transparency when they used to be staircases between walls; the duality between visible vault and the design of the original through the recovered rosette; the supported structure facing the exempt, massive against light, stone against metal, open and transparent against closed and dark; internal plasticity carved on the mass against the external plasticity from the added.

3.2. Time and memory

The project is approached as an *archaeological excursion*, which crystallizes a symbolic-theological thought, but also the political and social power of the Borgia family and the Duchy of Gandía. When it is finished it will act as an *axis world*, axis, or visual landmark of the cloister, that is, a symbolized part of the general object that channels the temporary reading and the opening of time-memory. There is some *death* evoked, figurative, and inferred in intervention, through impossible ruin; the previous one rescued, or the ruin of not seeing a clear and different time, but complex overlapping times. The *design* will link art and heritage. The *remnants* left will show the law, or what remains of it in some cases. The remains bear witness to other times, other structures that do not remain except in the imagination of the viewer who recomposes space-time. Through figurative *mosaics*, or irreplaceable elements that show different temporary natures, which at the same time configure *aporias* of their own cultural and ritual aspects, of access, travel, understanding, dialogue with the past, etc. This creates a *theatrical effect* that separates and distinguishes the times, those actors and the spectators, some spectators from others. But also the theatricality derived from what is produced in space and the typical acts that make up a representation of scenes proper or inappropriate for the anthropomorphic function of space, now paradoxically faced with a floating sculpture as a staircase and its dialogues. That, taken to the limit, it even constitutes a certain *progressive Museumization*, as the building became a container for cultural activities, when, in its history, culture derived from matter, art incorporated into stone, not from its exteriority. Especially, when culture was a set of creative displays and today culture is understood as

"showing the way of life of contemporary society" or culture of the masses. The paradox of these encounters provides images or dialectical sequences that open the appearance of memory, and with it, the querying present, past and future. This questioning activates the circularity of time, and impels us to position ourselves interpretively in the role of the monastery in our constitution as a society. These dialogues are complemented by the *ceremonial aporia* or, also, functional incongruity, derived from separating its teleological and theological objective from the body, from the trampoline staircase introduced, distancing the reasons that illuminated it, its *liturgy* and *ritual*, by a modernized reading of the same, which reveals other additional questions: transparency, multiplicity, versatility, lightness, etc. The new staircase will mark a new liturgy of routes, the sequence of spaces, of additional historical readings, which will provide the viewer with more information about its character. And with it you will have a greater dimension of the memory of it. Things you never thought of before will be clarified and with it, you will understand your limitation. You need to know to understand.

CONCLUSION

The patrimonial value of what was found needs to be shown. However, alterations over time do not give credit to how it was and how it evolved. In order to explain all this from its remains, it is necessary to work with the remnants in the way that the added body of the staircase helps make what is not seen to be seen. Always together with the viewer; who must weave the apparent information, the forced, the expressive, the erased, the subtle and the imaginary reconstruction. The objective is to remove the multiple temporary elements present in the workspace, turning the staircase into a agitator of nuances, or into a complex temporary device. That at the same time clarifies; articulate the activation of time without aim. Time that, *a priori*, is trapped between its immobilized past and an eternal present, in the case of having designed a functional neutral element without a stylistic character, as the law prevents. The activation of time, the reflection on possible sequences, even the opening of a possible future, challenges the present technical predominance and the utilitarian logics placed in society. Thus allowing another scope or understanding of other criteria, as well as the re-functionalization of history. The definition of the device followed is equivalent to the process of symbolizing language, here rehearsed its entire unfolding through the drawing, avoiding contradictions against fact. This reflection of language supports a certain semiotics of time.

PAPER #3.22

WORKSPACES EVOLUTION, TOWARDS THE NEW COWORKING SPACES

Alicia Llorca Ponce[a], Franca Cracogna[a]
[a]Universitat Politècnica de Valencia, Spain

ABSTRACT

Several criteria have led the design of administrative spaces throughout time; this paper explores these rules from the origin of offices down to the recent appearance of coworking spaces. Our intention is to make progress in the knowledge of the aspects that should be kept in mind when designing the office of the future. Workspaces are created from the needs derived from productive activities and from the different tasks required. By the analysis of the literature over the history, we conclude that, in the course of time, offices have undergone a constant change guided by the search of productivity and have also been persuaded by the promotion of the corporate image and its firm. Among the factors that have influenced the office design, without a doubt, the technological advances that have sped up since the end of the twentieth century with the incorporation of the information and communication technologies have been key both in workspaces design and daily life activities. The creation of thoughtful and different spaces that consider teamwork, user comfort, exchange, community life and freedom of movement that develop meetings and facilitates creativity and synergies is required. The change in the way of working and, especially, in the characteristics of the tasks to be carried out, have conditioned the unstoppable evolution of workspaces and it could be said that it is difficult to find a list of criteria to follow to ensure the success of a type of offices because each company and activity requires different conditions.

KEYWORDS

Real estate market; office space; office design; co-working.

INTRODUCTION

Workspaces have been transformed throughout history. The changes in the way of working and also in the needs and lifestyles of the workers have been the driving forces of these transformations in office spaces (Harris, 2015). These things, in turn, have witnessed several changes that have been sped up during the last decades, but it is true that there are also a lot of workspaces that are still heirs of the past. To be able to understand and adapt to the current affairs and the future of administrative spaces it is interesting to analyse the evolution of workspaces in the last century and the events that have conditioned its transformations. This article begins by describing the evolution of offices from its origins to the latest developments and proposals opening the way to tackle other interesting and relevant aspects of actual and future office design.

1. CHANGE FACTORS. EVOLUTION OF WORKSPACES

First historical evidences of spaces where administrative tasks were carried refers us to the Sumerians and Ancient Egypt. Already in the fifteenth century Francesco di Giorgio established the bases of what could

[1] Quoted by Hernández (2002)

be considered a prototype of the modern office in his treatise "Casa degli Officiali"[1]. He pointed out that all the rooms of this office prototype must flow around an open atrium with a single entrance. In 1560 the Uffizi Gallery was built, which is considered the first office building of the modern age and an archetype of many others. Two centuries later with the start of the industrial revolution on Great Britain, a radical transformation of the production methods took place, an increment of specialization and division of tasks and a significant increase in administrative. Centuries later, the development of the information and communication technologies, will mean new radical changes on the way of work. The industrial revolution makes possible the appearance of new studies that focus on the optimization of process as Taylor's research reaching its highest point with the publication in 1911 of the *Principles of Scientific Management*. Taylorism looked for a productivity increase by proposing a hierarchical organization of work where the business management takes the strategical decisions and divides the tasks between the workers. Leffingwell was a Taylor disciple who centred his investigation on the administrative work and publishes in 1917 his book *Scientific Office Management* and then, in 1925 a manual called *Office Management*. The objective of this manual is to rationalise the movement of office work and applied, it entailed a constant control over the workers and their job. Years later, during the Great Depression the approaches of the human relations movement began to gain strength, which culminates with Elton Mayo's work, *The Human Problems of an Industrial Civilization*, where he questions Taylor's vision. In the 1960s, the work of Douglas Mcgregor is published with a theory called "Y Theory" that is positioned against Taylorism that is associated with "X Theory". Y Theory defends that the management should be opened to the individual recognition and to the stimulation of workers to reach their goals instead of supervising them. Then, from the 80s, the development of computers entails a new transformation that will free the workers from many tasks and also allow them to focus on creative tasks, with this emerges a new class of workers, the knowledge workers, those who will be the most important resource of the companies. At the same time appears a new theory, the "Z Theory" by Ouchi, (Saval 2014). it was inspired by the Japanese models and proposes horizontal and flexible organizations with capacity to adapt to changes.

In addition to the organization types, technological advances allow and inspire new office designs. By the 50s and the 60s the *General Office or Bull Pen* appears, based on the cellular office which consist on an open floor where the workers are in the center and the executives in the perimeter. Years later the *Open Plan Office* rises, another open floor design that allows workers communication. In Europe, after decades without new proposals, appears in Germany in the year 1958 the *Bürolandschaft* translated as the *Office Landscape*, a more organic and natural design which offers more flexibility and adaptation but also noise and more distractions. Continuing with the office layouts, in 1964 is presented the *Action Office* by Herman Miller and Robert Prost, a furniture design where the worker is the main object. Its creators, ahead of their time, claim that the role of the worker will change and that the repetitive work was being replaced by the "knowledge work", they think that the office is a thinking place. Modularity and flexibility should help adapt the spaces and anticipate to new changes. *Action Office* was well received by theorists, but it wasn't delivered because of its high price (Saval 2014). They created later the *Action Office II* which was related with *System Furniture*, adopted by the *Open Plan Office* and defended by the Modern Movement.

After the second half of the 80s the United States and Europe started to follow different paths. In Europe, the oil crisis shows that open concepts were no longer profitable; workers

wanted more privacy, and, in this period, a pathology known as *Sick Building Syndrome* (SBS) appears. Office landscape wasn't valid anymore, so new designs that give answer to the objective of having open offices but maintaining the workers privacy appears. On the other hand, on the United States the *Open Plan* evolved to the *Cube Farm*. From the latest 80s, personal computers and digital technology development give rise to new ways of working and needs because of that many workspaces design became obsolete.

2. CHALLENGES OF WORKSPACES. DESIGN AND PRODUCTIVITY

The most important challenge of the companies of the 21st century is the need of continuous innovation to maintain it activity. Being competitive requires the creation of new products and adapting to a continuously changing market. More flexible spaces with higher connection are required (Harris, 2015). It is imperative to provide spaces for workgroups rather than hierarchy especially in sectors related to digital and knowledge

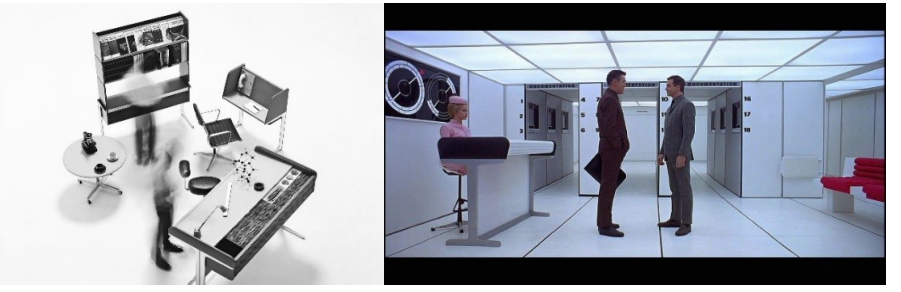

Figure 1. Action Office by Robert Prost and Action Office desk in the film 2001 a Space Odyssey. Concept by Robert Prost and Design by George Nelson. economy; office is a place for workers to collaborate developing ideas, strategies and solutions. In offices designed for today and the future the workspace is considered as a hub, it is a network where workers share knowledge and collaboration (Harris, 2015).

Nowadays the new context of work allows more flexibility and autonomy to the workers. With that appears the *Agile Working* which says that work is a task, so it is not tied to a place. This philosophy allows a cost reduction in companies and has a positive effect over sustainability reducing trips and energy waste. There are also some disadvantages, recent studies demonstrate that higher levels of innovation are produced when there is interaction between team members, so it is not a surprise that in some cases remote working leads to less incomes and productivity. Face to face is the most valuable way of communication, (Pentland, 2012; Waber, 2014),[2] casual meetings between workers improve the results. And while ideas can emerge in social places, it is really in workplaces where they are shaped and become real.

Related to *Agile Working*, a new concept of *co-location* appears, to refer to those workers that do not always occupy the same workplace. If part of the employees or part of the time is worked remotely, the space per worker is reduced and if workers occupy different places each day there will be more communication, making knowledge flow to favor innovation. In the past, private offices and cubicles were the most common type of room in workspaces, but nowadays collaborative spaces where knowledge and ideas can flow are needed.

Collaboration, creativity and communication are needed as well as concentration, privacy, contemplation or relax in actual office designs. It means, diversity of spaces is required. (Harris, 2015).

Beyond organizational issues and the tasks to carry out, workspaces should attract and keep the staff. In companies where talent is the fundamental source of productivity this idea is primordial. Today's workers consider that work is only a part of their life, so having different spaces to practice sport, eat healthy or take a break to have a balanced life is valued, especially in non-traditional sectors. Silicon Valley companies were the first adopting this vision in their designs. With that, Active Design concept emerged, outlining that offices should offer more active and collaborative spaces as well as other quieter or different as well as bicycle parking or changing rooms (World Green Building Council, 2014).

From here on, we are going to analyze how performance and productivity are conditioned by design. There are two key points, on one hand, the ergonomics and, on the other hand, the flow of the workers (Riaz, Shoaib & Sarfraz, 2017). Productivity is influenced by design because it affects your concentration capacity, efficiency, creativity or idea generation. Design should contemplate environmental sustainability, workers health and productivity, which is also affected by workplace comfort. Following the 2014 World Green Building Council these last two elements are specially influenced by indoor air quality, thermal and visual comfort (daylighting and lighting), noise and office layout.

Indoor air quality

Air quality is based on ventilation indices, pollutants and CO2 concentration. Studies affirm that productivity could be increased between 8 and 11 per cent with air quality improvements, (Loftness, Hartkopf & Gurtekin, 2013). On the contrary, studies state that poor air quality and elevated temperatures diminish efficiency, (Anderson 2006). Good ventilation helps to reduce malaises; therefore, sick leave diminishes too, and it is beneficial for workers health and companies' productivity (Milton, Glencross & Walters, 2000). High CO2 emissions cause fatigue and affect to decision making. Covid-19 is an actual

[2] Quoted by Harris (2015)

proof of the importance and impact of good ventilation over health and companies' sustainability. As Daisey (2013) indicates, increasing the ventilation ratio and reducing polluted air concentration -computer systems and building occupants being the principal sources- are needed to improve air quality. A good natural ventilation system in office spaces will be a benefit for workers health and for companies because it entails an increase in efficiency and in savings from reduction in energy consumption (Borgeson & Brager, 2011)

Thermal comfort
Thermal comfort has a positive effect over workers satisfaction and productivity, and it is influenced by six factors. Four of this factors are related to work environment, such as air temperature, mean radiant temperature, air relative humidity and air velocity; the other two are related to personal factors, they are human metabolic rates and insulation through clothing (Katafygiotou & Serghides, 2014). All these factors and local weather must be considered in building design to create satisfactory office spaces.

Visual comfort
As previously mentioned, well-being, productivity and efficiency are benefited by visual comfort among other parameters, furniture and lighting being the most important elements that affect both workers' performance and health, (Riaz, Shoaib &Sarfraz, 2017).[3] Visual comfort depends on some design parameters such as lighting conditions and views. The access to natural light and the artificial lighting quality to avoid blinding is also significant. As Al horr (2016) notes quoting Mac Nicholl and Lewis (2014) work, "geometry of windows, photometry of surfaces, amount of glazing, etc., all have an impact on the illumination levels in a work area". Regarding exterior views, proximity to windows and green spaces have positive effects over productivity too, (Newsham, 2008). Prioritising natural lighting is making a bet where both occupants and company wins; workers have higher satisfaction levels and the company could save costs.

Noise
Large number of research papers and studies consider that employees' productivity and efficiency is negatively influenced by noise because they could cause frustration, high stress levels or bad concentration (Leather et al. 2003; Seddigh et al. 2014; Witterseh et al., 2004). Some studies reveal that there are beneficial noises too, such as background sounds or lower intensity noises (Danielsson, 2015).

Office layout
According to actual researches workers have different points of view about the factors that could affect comfort or productivity depending on their office layout. On one hand, the enclosed private offices occupants consider that this type has positive impact on productivity because it avoids distractions. But, on the other hand, Open Plans occupants think that this kind of layout has negative effects because there are more interruptions or distractions, (Al horr, 2016), but they also recognize that there is an increase of productivity bounded to the access to informal meeting points and connections between employees. Special mention on this point to the importance of spaces that invite to healthy life as Active Design, mentioned previously, suggests.

Privacy versus interaction and communication
People need concentration to carry out certain activities, so they need spaces with no distractions. In contrast, activities related to innovation have better results on spaces that encourage teamwork, where communication and discussions are fundamental. In

[3] Quoted by Al horr (2016)

this regard, refreshment spaces play an important role, but sometimes they could be considered as a distraction (Haynes, 2017). Placing refreshment spaces where they cannot interrupt or distract other workers is something to consider during the design period. Another important factor is the use of printers, photocopiers or kitchens could be used to foment interaction on workspaces (Haynes et al 2007; Gladwell, 2000; Dobson & Suckley, 2015).

3. THE FUTURE OFFICE

According to Myerson and Ross (2003) proposal, the 21st century office has evolved into four key themes: Narrative, Nodal, Neighborly and Nomadic office. *Narrative office* expresses the firm personality and principles, giving visual incentives to the workers. *Nodal office* works as a knowledge exchange platform, betting on flexibility and promoting multidisciplinary projects. *Neighborly office* intends to put an end to hierarchical organization bringing workers closer and creating a cooperation and engaging environment. This type of workspace counts on different types of engaging spaces such as cafeterias, open areas and meeting points. *Nomadic office* describes workspaces located on buildings or places that are not designed specifically for working but have amenities too, such as airports or coworking. All these types of offices converge on the disassociation of office and workers empowered by digital technology to be connected all the time and everywhere.

Telecommuting has been greatly intensified recently with Covid-19 pandemic; this is possible thanks to the new technologies. Reduction of commuting time and cost or the possibility to balance work and other activities are some of the advantages of teleworking. By contrast, workers isolation and the loss of control over employees are negative factors of this type. Public buildings such as cafés or libraries could function as workspaces, this is the *Flex Office*, which is defined by Van Meel (2015) as an intermediate typology between the Nomadic and Nodal office of Myerson and Ross joining the *Nonterritorial Office* of Chiat.

Coworking, a typology that fits well on the nomadic office of Myerson and Ross (2003), is a place where entrepreneurs, freelancers, SMEs and start-ups share spaces, creating synergies. It is born as an alternative for telecommuting or *Home Office* (Klauck, 2005), avoiding the isolation of working from home and offering amenities like an office. These spaces emerge to answer the needs derived from the new working methods, the new creative economy and the new information technologies. The creation of collaboration and community between users obtaining synergies is the main idea of coworking spaces.

The development of coworking spaces is accelerated by the economic difficulties from the 2007 crisis. Due to staff reduction in companies, many workers had to start their own business finding in coworking spaces great amenities as internet connection, IT services and flexible spaces. Serendipity and synergies occur thanks to coworking (Messina, 2007), professionals could find partners, clients and new ideas to make their business rise, productivity boost and their business network expansion. To ensure user's continuity, coworking owners try to facilitate their work and concentration and they also offer several services such as legal and economic consulting, training, workshops or mail service.

CONCLUSION

Workspaces have changed and evolved due to social progress and production activities changes influenced by technological advances. Office spaces had to adapt to new processes and technology. At present, the worker is considered an intellect strength, but there has been an important shift from manufacturing and repetitive tasks to creative and ideation activities to get to this. Many professions have been replaced by automation done by computers while more spaces are needed today to crate and innovate. Workers are the most important asset for companies, they are not just machines repeating tasks; for this reason, the workers' comfort and flexibility are nowadays fundamental for a firm to success.

Relationship between design, workers wellbeing and productivity has been a transcendent factor too. Noise, thermal control, lighting and layout design are pointed out as the most important factors that relate productivity, workers efficiency and design. Noise has a negative effect reducing worker's ability to concentrate, by contrast, thermal control, good light, natural if possible, and outside views increase productivity. There are many different interior layouts and all of them have advantages and disadvantages. For example, while noise causes distraction on the Open Plan, interaction and communication have the opposite effect, increasing productivity and innovation possibilities; on the other hand, cubicle office problems and advantages are completely different. In addition, refreshment and sportive spaces should be provided in today offices.

Nowadays workspaces should be prepared for a constantly changing productive environment, for this purpose, flexibility, adaptation capacity and communication, ideas exchange and teamwork fomentation are key points but offering concentration and quieter spaces too. Beyond efficiency and productivity requirements, interior layout plays an important role attracting new talents. Workers from the creative and knowledge economy value pleasant environments with personality and amenities to maintain a balanced and healthy life.

Distancing between work and workspaces is enabled by the transformations derived from computers development, the Internet and digital technology. Remote work separates workers and fixed offices reducing workstations and promoting new interaction between workers because they are not grounded to workplaces. Today what we understand as a workspace has extended to the public space too, work happens in many places. In this context, due to its lower costs, well-cared environment and the ability to connect with other professional and to achieve greater business opportunities, co-working adapts to the autonomous professional, entrepreneurs, freelancers, SMEs, start-ups and today's market.

BLOCK 4: SMART CITIES VS. TECH CITIES

PAPER #4.01

IS DUBAI A NEW PARADIGM FOR SMART CITIES?

Sabeen bin Zayyad[a], Thomas Patrick Keenan[a]
[a]University of Calgary, Calgary, Alberta, Canada

ABSTRACT

As one of the fastest growing urbanized cities in the world, Dubai is aiming to become the smartest city on the planet by 2021. At the launch of Dubai's Smart City strategy in 2018, the ruler of Dubai tweeted, "Our goal is for the entire city's services and facilities to be available on smartphones". McKinsey Global Institute states that cities are becoming more habitable and accessible as they get smarter. Technology is becoming part and parcel of citizens' lives by virtue of having access to all types of information in an instant. In addition to keeping pace with innovations in technology, cities also face the challenges of social and economic exclusion. Current literature defines smart cities as ranging from those that use technology as tools to make better decisions and improve the quality of life, to using data to increase efficient delivery of government services to its citizens, to making cities more effective in their operations. Current literature also posits that smart cities do not necessarily mean intelligent communities - making cities better and inclusive. In other words, inclusive means that all citizens should be able to have access to essential services including technology to improve the quality of their lives. This paper will begin by tracing Dubai's journey to become a smart city. The second part will examine the social and economic challenges it currently faces in providing access to the Internet and government services for the majority of its residents. The paper will conclude by proposing that Dubai's approach to becoming not only a smart but also an intelligent city should begin by re-evaluating the alignment of the application of various types of technology with the needs of its residents rather than focusing on the economic return of investment that this implementation brings forth.

KEYWORDS

Smart city; intelligent community; technology innovation; community development; Dubai.

INTRODUCTION

> The 19th century was a century of empires, the 20th century, a century of nation states. The 21st century will be a century of cities (HuffPost 2017).

The World Bank (2018) and United Nations (2014) state that, over 55 per cent of the world's population live in urban areas and that number is expected to increase to 66 per cent by 2050. More and more people are moving to cities in search of job opportunities, better wages and access to basic services such as affordable housing, health care and education. Unfortunately, this does not always translate to a better quality of life. The pressure on cities to meet these minimum needs is very high. The development of diverse lifestyles, declining infrastructure, climate change, ageing population, and more recently the influx and integration of refugees are some of the 'newer' challenges that cities currently face. In their attempts to manage existing economic, social and environmental resources, city officials are increasingly turning to the notion of a smart city to not only improve the quality of the lives of their citizens but to also increase the efficiency of how cities operate and reduce costs.

So, what is a smart city and how is that different from an intelligent community? How does the idea of a smart city align with sustainable development?

1. SMART CITIES, INTELLIGENT COMMUNITIES

According to the Intelligent Community Forum (2015), a smart city approach makes cities work better by using innovations in technology to cut down on costs, increase efficiency and provide better services to its citizens. Gassmann, Böhm, and Palmié (2019) define a smart city as one that

> systematically applies digital technologies to reduce resource input, improve its people's quality of life, and increase the competitiveness of the regional economy in a sustainable manner (26).

Other definitions such as Manville's (2014) describes the smart city as one where a collective partnership is formed between government and non-government stakeholders to address the challenges of urbanization by providing solutions based on information and communication technologies. Pelton and Singh's (2018) characterization of a smart city is one that is not defined by its technology and application but, instead is a process that combines seven elements that are key to building a smart city:

• Meeting the needs of citizens – providing basic services of housing, education, health care, transportation and access to the Internet
• Sustainability / circular economy – tackling the challenges of climate change, pollution, urbanization, and growth in population while minimizing the wastage of resources
• Jobs and competitiveness – stimulating economic competition and growth by creating jobs and retention through retraining programs
• Smart planning and citizen support – involving all demographics of the population including youth to find answers to key questions around delivery of vital services, infrastructure, etc.
• Infrastructure and resources – effective and efficient delivery of key services to both citizens and businesses
• Technology and AI – meeting the needs of the community through the smart use of technology
• Security – ensuring protection against cyber-attacks, key infrastructure, natural and humanitarian disasters

Although the definitions of a smart city are many, it is important to note the difference between the concept of a smart city and that of an intelligent community. Defined as civic groups that strive to make urban and rural areas better places to live in, intelligent communities ensure that citizens are able to prosper in a broadband economy. Technology is not necessarily the primary focus of these communities. Instead, they aim to create an environment where citizens are engaged by providing access to technology to develop a highly skilled workforce, thus ensuring better employment opportunities resulting in an improved quality of life (Intelligent Community Forum 2015). The concept of and processes behind the creation of a smart city does not only require cooperation across different disciplines ranging from politics to economics, from social sciences to the law (Celino and Kotoulas, 2013) but is gaining increasing importance for governments who are looking for manageable and sustainable solutions to the rising urbanization of their cities. Given the interdisciplinary nature of a smart city, how do smart cities and intelligent communities translate into 'smart urbanism' where information and communication technologies are incorporated in an efficient and integrative manner to meet the challenges of a city's urban development? Although research into the area of smart urbanism is

very limited (Luque-Ayala and Marvin, 2015), it is becoming a more adaptable response to the challenges of urban growth in which the questions of who the smart cites are geared toward, the governing processes behind it and how this can be socially inclusive, begin to emerge in different urban contexts.

Proponents of smart cities remain divided on the development and implementation of ideas, potential solutions and possible outcomes. On the one side, there are those that want to develop smart city technologies that meet the immediate needs of city administrations and are sustainable, economical and effective. This group consists of mainly scientists and engineers who work in academia, private corporations and the government. On the other side, are civic organizations, policy makers and not-for-profit groups who find that technology-based solutions are extremely narrow in their application and do not take into consideration the addressing of political, economic and social challenges that exist within the urban milieu (Coletta et al, 2018). This dichotomy between a technology-oriented approach and a civic development approach highlights and emphasizes the disconnect between what municipalities think its citizens want versus what its citizens actually need. The approach of the former is top-down and functional determined by what it thinks is best for the citizens, whereas the latter involves the engagement and participation of the citizens to determine their needs and how best they can be met. Coletta et.al. (2018) state that the reasons behind this divide stems from providing short-term solutions rather than addressing the underlying causes of urban issues. They further state that regulations and the lack of partnerships between the public and private sectors highlight the inefficiencies and the inability of governments to deliver critical amenities to its citizens (Kitchin et al 2017). Instead, governments should draw upon

> the competencies held within industry and academia [to] help deliver better solutions through public-private partnership, leasing, deregulation and market competition, or outright privatization (Coletta et al 2018, 4)

Coletta et.al. also believe that governments are already outsourcing the creation of smart city technologies to the private sector. For example, consider the proposed development of a 12-acre parcel of land along Toronto's waterfront by Sidewalk Labs, an urban innovation lab and subsidiary of Alphabet Inc., the corporate parent of Google. After a competitive bid process, Sidewalk Labs was chosen as the "…successful Innovation and Funding Partner to help think through tough urban challenges…" (Waterfront Toronto, 2017). This partnership between Waterfront Toronto (a government agency) and Sidewalk Labs, has been described as a 'smart city' makeover of Toronto's waterfront area (Bozikovic, 2017, October 17). On their frequently asked questions tab of their website, Sidewalk Labs states that it

…proposes to focus on core areas it is uniquely suited to achieve and that the market or government are not able to pursue on their own, including limited deployment of core technologies necessary to achieve quality-of-life objectives that are not available in the market today.

This project has not been without its share of controversies. Many fear this supposedly limited use of "core technologies" will infringe on the liberties of citizens, thus bringing into perspective the role of digital governance in protecting these rights.

It is also important to note that a smart city does not necessarily translate to a better quality of life or a more secure one. It could be if the technology used was carefully planned and thoughtfully implemented (Pelton and Singh (2018). Celino and Kotoulas (2013) state that the adoption of Internet-based technologies in urbanized cities around the

world is evidence enough that Internet-based solutions are effective in providing tangible services and solutions to its citizens. Yet, they make no mention of maintaining the quality of citizens' lives or their security vis a vis their rights as mandated by their governments. Keeping these two perspectives in mind, we now trace Dubai's journey to becoming a smart city.

2. DUBAI'S JOURNEY AS A SMART CITY

> We are building a new reality for our people, a new future for our children, and a new model of development (Sheikh Mohammed bin Rashid al-Maktoum, 2018)

A city of superlatives, ambitious, glamorous, and expensive are some of the adjectives used to describe the Emirate of Dubai. From its origins as a tiny fishing and pearling port in the early-20th century, Dubai today has established itself as a 'city of opportunity' according to PricewaterhouseCoopers sixth edition of its 'Cities of Opportunity' report on in 2014. In addition, Dubai was ranked 12th in the intellectual capital and innovation sector and 13th in terms of technology readiness. Its ranking overall was sixteen out of a total of thirty cities. However, Dubai's ranking dropped a notch in PricewaterhouseCoopers report of 2016. In terms of readiness in technology it stayed the same – 13th but dropped to 13th place in intellectual capital and innovation. It is important to note that it was the only city from the Middle East and North African region to be included in both these reports. With the diversification of its economy away from oil, Dubai has constantly reinvented itself to

Year	Initiatives	Purpose
1999	ICT strategy	• no information available as to its purpose
2000	Dubai Internet City	• tech hub to nurture talent and creativity • www.dic.ae
2001	Dubai e-government	• all government services are made available online • reduce bureaucracy • more accessible • ease the lives of its residents • previous website – www.dubai.ae
2013	Dubai Smart Government	• formerly known as Dubai e-government • www.smartdubai.ae
2014	Smart Dubai	• government office in charge of facilitating Dubai's transformation into a smart city and promote the city into an efficient and seamless experience for its residents and tourists • some key initiatives include Dubai Blockchain Strategy, the Happiness Agenda and the Dubai Paperless Strategy • www.smartdubai.ae
2017	Smart Dubai 2021	• a strategy designed by the Smart Dubai Office to respond to the changes that are shaping Dubai by preparing Dubai to become a world-leading city by 2021 • is a 'revolutionary new vision' for a smart city by making Dubai the 'happiest' city in the world • to promote advances in technology that benefit its economy, resources and its residents • www.2021.smartdubai.ae

Table 1. Timeline of Dubai's transformation into a smart city.

face the urban challenges that are similar to that of other growing cities in the world. The unusual demographics, rapid urbanization, form(s) of governance, and globalization are some of the challenges that require Dubai to continually adapt the way it provides and delivers the services needed to sustain a growing population. A city of approximately 3.2 million people where ninety-two percent are expatriates (Dubai Statistics Center 2018), Dubai's journey to becoming a smart city began in 1999 with the initiation of its ICT Strategy. Table 1 below illustrates when these initiatives were launched and the purpose behind them.

After conducting a thorough review of the Dubai Smart government, Smart Dubai and Smart Dubai 2021 websites, the authors found that there were common key terms used to describe each of these three initiatives. Some of the common terms used across both the websites were:

a) to be the happiest city in the world

b) to use innovations in technology such as blockchain, Internet of Things (IoT) systems, and AI applications so as to become the smartest city in the world

c) make city experiences seamless, efficient, safe, personalized, deliver enhanced quality of life and ensure sustainability

This begs the question as to how do each of these initiatives differ from each other in Dubai's bid to join the ranks of other smart cities in the world? At first glance, the initiatives are iterative. The themes are revisited over and over again without any tangible incorporation of new ideas. However, rather than being critical about this, the authors believe that the initiatives should viewed as incremental phases towards achieving Dubai's goal amongst others, to become the smartest city in the world. In addition, Dubai can and should be viewed as a pioneer in its attempt to become the first smart city in the Middle East and North Africa region (Virtudes, Abbara and Sá, 2017).

3. SOCIAL AND ECONOMIC CHALLENGES POSED

> We are making Dubai the happiest city on earth by embracing technology innovation making Dubai a more seamless, safe, efficient and personalised city experience for all residents and visitors (Smart Dubai 2021 n.d.)

Using Dubai's Transformation Agenda model below (Figure 2), the authors have chosen two of the six 'strategic themes' as a guide to illustrate the social and economic challenges that Dubai's faces in embracing the notion of a smart city. The 'city experience' and 'emerging technologies' were chosen because they offer an insight into two important elements that are crucial to building a smart city – affordability and liberty.

Figure 1. Dubai City's Transformation Agenda. (Smart Dubai 2021 n.d.)

3.1. Affordability of the city experience

Human capital is the bedrock of a nation's development. Given Dubai's highly unusual demographic where expatriates outnumber the citizens, this can pose a challenge where terms like happiness, resilience, well-connected, well-planned do not necessarily translate into what Smart Dubai 2021 deems or identifies or states on its website as "… an unmatched urban experience." Being able to 'connect' with the rest of the world is important in this era of globalization. According to the World Bank (2016), only 15%

of the world's population can afford access to the Internet with 60% having no access at all. In addition, despite cell phones being the main device with which to connect to the Internet, approximately 2 billion people do not own one (World Bank, 2016).

In 2013, the Dubai government launched an initiative whereby all government services would be made accessible on mobile devices by 2015. Although only "…96% of public services in the government's 337 most significant departments had successfully gone digital" (Smart City Press 2018), the ruler of Dubai set a new target. It wanted at the very minimum 80% of its residents to actually access government services using their mobile devices. Therein lay the challenge of how both residents and visitors alike could have a seamless experience whilst in Dubai. What is even more daunting is the fact that despite "…active mobile penetration skyrocketing above 260 percent…" (Salem 2016), the financial costs of being able to afford access to the Internet remain unaddressed to date. According to Hassan (2018), of the 9.3 million residents in the UAE in 2015, 89% were migrant workers with most of them being semi-skilled or unskilled. It should be noted that the statistics on what percentage of Dubai's labour force constitute unskilled workers is not available. Although the list is not comprehensive, this demographic includes construction workers, housemaids, drivers, security guards, and building caretakers to name a few. With an average income of US $362 per month (Hassan 2018), most of their income is remitted back to their home countries to support their

	Smartphone plan (talk, text & data)	Basic phone plan (talk & text)
Etisalat	Waselgo Extra Large US $88.48 per month + 5% tax 3.5GB data 175 flexi minutes 3 favourite local numbers	At time of writing, the Etisalat website was undergoing a scheduled system maintenance despite the authors' numerous attempts to explore other plans
du	US $40.84 per month + 5% tax Includes 3GB of data + 3GB 'free' full data (available plan at time of writing) 150 flexi minutes	At time of writing, du requested the authors' contact details as they were 'currently working on improving our eShop experience'
Rogers	US $56.56 per month + 5% tax Unlimited in country-wide calling, text, picture and video messaging including voicemail, call display, call waiting & conference calling Includes 10GB of data	US $26.40 per month + 5% tax Unlimited in country-wide calling, messaging, call display, call waiting & conference calling
Bell	US $56.56 per month + 5% tax Unlimited in country-wide calling, text, picture and video messaging including voicemail, call display, call waiting & conference calling Includes 10GB of data	US $30.17 per month + 5% tax Unlimited in country-wide calling, messaging, call display, call waiting & conference calling

Table 2. Comparison of phone plans between Dubai and North America

families there. One of the ways in which they are able to keep in touch with their families and the world is by using their own mobile devices or borrowing one from friends and colleagues. Despite Dubai's desire to ensure that access to the Internet is available to all, the telecommunications market in the UAE is dominated by two providers – Etisalat and the Emirates Integrated Telecommunications Company (EITC), represented as the brand "du" (ITU 2017). The former is mostly owned by the UAE government with the rest of the shares being publicly traded (Etisalat 2019). Du has a similar ownership structure with different entities of the UAE government owning most of the company and the rest by public shareholders (du 2020). What this means is that competition is limited, thus making the plans unaffordable for many. The table below illustrates the price point of similar plans from the websites of the two providers in the UAE and how it compares to similar plans from the websites of two providers in North America, using pre-paid plans.

Given the average monthly income of these semi-skilled and unskilled workers is only US $362, this makes it very costly for them to connect with their families back home. Allocating between approximately 12-26 percent of their income towards staying in touch with their family and the world does not seem feasible or sustainable in the long-term. The city experience for them begins to lose the connection to simplified living. It begs the question whether this particular demographic who form a large segment of the expatriate labour force has been taken into account in the planning of Smart Dubai? In an Access and Use of Information and Communications Technology survey carried out by the UAE Telecommunications Regulatory Authority (2008) and conducted over a period of 6 months, 65% of the respondents surveyed in 1350 households "…noticed reductions in prices of telecommunication services in the past year or two…" (8). It should be noted that the portion of households surveyed represented only 0.2% of the total number of households in the UAE in 2008.The survey also concluded that 66% of these households had access to the internet. A total of 2 people per household were surveyed and "96% of respondents…had access to a mobile phone which may be owned by the respondent or another party." (12). Although statistics on the number of users that have access to the Internet in the UAE vary from 90.6% to 94.3% (CIA 2016, ITU 2017), the type of demographics surveyed is not clearly stated. This makes is very difficult for the authors to understand the perceived impacts of the various initiatives launched by the Dubai government. What also needs to be taken into consideration is, whether any of the initiatives that Dubai has launched will eventually lead into its transition to an intelligent city where inclusivity becomes a defining factor in the quality of their lives. The advent of smartphone applications such as WhatsApp allow users to communicate with their family and friends at no charge (by accessing free WIFI connectivity), is fast gaining a huge following. The smartphone applications provided by Etisalat and du such as BOTIM, are not free as users are required to pay when downloading the application. With the incremental costs of living, applications that provide communication services at very little to no cost is a boon to many who struggle with being able to afford access to talk and text plans. However, this also comes at an intangible price for many as the next challenge will outline.

3.2. Liberty meter with emerging technologies

"The challenge moving forward is choosing the right technologies to incorporate" according to Danish Farhan of Xische and company in a recent article written for Gulf News. The context within which it was written was a nod to how the transformation of Dubai's government will be based on innovation. This innovation means the deployment of the best

technologies such as blockchain, the Internet of Things (IoT) and artificial intelligence. What is equally disruptive in the embracing of new technologies is the government's reluctance to allow technologies that enable free voice and video calls using the Internet. Commonly used across the world, these Voice over Internet Protocol (VoIP) applications such as Skype, FaceTime, Viber and WhatsApp, are banned not only in Dubai but in the entire UAE. Although the text features of these services are allowed, voice and video calling are not permitted. In Dubai's efforts to become the happiest and smartest city in the world, this does seem in direct contrast to its Smart Dubai initiative launched in 2014. Many residents in Dubai have called for the ban to be lifted stating that it was affecting the development process in Dubai (Habib al-Mulla 2018). In a 2019 Twitter post, prominent Dubai businessman Khalaf al-Habtoor stated that these free VoIP services

> …improved the lives of residents and investors…that must be provided as we strive to be a smart city. Stop the monopoly mentality of telecommunications companies.

Many residents have resorted to using virtual private networks (VPNs) to work around these restrictions. In 2019, the UAE's Telecommunications Regulatory Authority issued a statement saying that there were no laws preventing the use of VPNs as long as it was being used for legitimate purposes such as "…to gain access to internal networks via the Internet." The interpretation behind what would be legal and illegal is broad. In an article on their website, a well-known law firm in Dubai, Al Tamimi and Company state that unless 'nefarious' content was going to be accessed, the authorities were less inclined to stop a user from accessing the latest episode of a television series not yet available in Dubai.

Figure 2. Etisalat response to a customer regarding access to Skype. (Gulf News 2018)

Both the telecommunication providers Etisalat and du have fee-based VPN packages that allow users to make calls via the Internet using applications supported by the providers, such as BOTIM, C'ME, HiU Messenger and Voico UAE. Given the geopolitical tensions that are constantly present in the Gulf region, it is understandable when certain applications are not made completely available to residents in Dubai and the UAE. Citing encryption and the UAE's 'regulatory framework' as reasons for the ban (Taylor CNBC 2019), Dubai's approach to the use of telecommunications technologies is understandably cautious vis a vis their national security. One could argue that this is not much different than the precautions taken by other countries in the world. The executive director of the UAE's National Electronic Security Authority, Mohamed al-Kuwaiti (2019) acknowledged that the enabling of increased connectivity in the country meant that the government needed to reassess how national security could be balanced with access to technology. At the time of writing, Microsoft, Facebook and Apple were in discussions with the UAE government on lifting the ban on their VoIP applications. Regardless of the outcome, a fundamental question remains – if Dubai is to become the happiest and smartest city in the world, how does restricting the freedom to select what technologies its residents embrace, enhance its development? While

leading democracies like the USA, Canada, Britain, France and Germany monitor their citizens' use of the Internet, Dubai restricts and monitors its residents' use of the Internet. Although, more control may be gained by cities in restricting available technologies and tracking their usage by their citizens, it is not sustainable in the long-term (Kar, et al 2019). Cities need to facilitate their citizens' interactions with different technologies in order to better processes, resulting in effective outcomes. In the planning of its initiatives, Dubai needs to enable and integrate a broad range of technologies that will allow for human progress. Granted that the security of cities and their nations is vital to a viable future, embracing new technologies while restricting access to them does not mitigate the challenges associated with urbanization.

CONCLUSION

Smart cities make cities run better by creating efficiencies through technology, whereas intelligent communities focus on making cities better by providing access to technology and developing a highly-skilled workforce. Both intend on increasing the quality of life for its citizens. Both are necessary for urbanization to prosper. However, Dubai's path geared towards developing a smart city requires consideration of the social context rather than the focus on economic return of investment that technologies bring. What this means is that the inclusion of "…citizens, urban dynamics, and citizen participation in public life and decision-making" (Celino and Kotoulas 2013, 9) is important to deliver tangible solutions to a city's inhabitants.

The authors propose three recommendations they believe are crucial to building upon the existing platform of Dubai's current initiatives to becoming a smart city:

• Digital connectivity – just having high-speed Internet is not enough. Providing access to all its residents is important, especially in areas with weak cellular coverage and access to publicly available WIFI is desired but not available. This would require Internet service providers Etisalat and du to streamline processes to improve services. It would also require them to review industry standards, assess current levels of connectivity available, and foster greater competition in the telecommunications industry with a goal of reducing the financial burden that is associated with accessing the Internet.

• Erudite workforce – as new technologies emerge, it is important that all sectors of the labor force are trained and prepared to use information and technology effectively. Greater collaboration needs to take place between Dubai's educational institutions and employers where opportunities such as work-study programs, internships, lunch n' learns are encouraged and created.

• Stakeholder advocacy – with Dubai positioning itself as a smart city, the government should engage in broader collaborations with its residents in building a better future by involving them in open forums, government-resident task forces and resident surveys, to understand how communities work with different technologies. It needs to analyze the dynamics between the public sphere, private sector and communities, and explore best practices to engage the stakeholders in opportunities for them to explore new ways of doing things that are more efficient and cost-effective.

As new technologies develop, Dubai needs to ask itself if its initiatives can be adapted to the changing economic, social and demographic variables? What implications does this have in the delivery of services to its residents? Are their initiatives integrated enough to provide alternative solutions to fulfill, support and sustain the needs of their residents? These and many more important questions deserve further research so as to achieve better collaboration between the government and its residents. Rather than simply focusing on the economic return on investment that the

application of various types of technology will bring, Dubai needs to apply technology to meeting the needs of its residents, improving the quality of life and strengthening the economic and social fabric of its communities if it is to achieve its goal of being the happiest city in the world.

PAPER #4.02

PERFORMING AND MEASURING SMARTNESS GIVING GROUND TO URBAN INTELLIGENCE BY AN ALTERNATIVE METRIC

Julien Lafontaine Carboni[a], Dario Negueruela del Castillo[b]
[a]ALICE, Swiss Federal Institute of Technology (EPFL), Lausanne, Switzerland
[b]University of Zürich, Switzerland

ABSTRACT

Since the emergence of cybernetics and the growing prominence of the use of IT as tools and instruments to develop and manage urban spaces, the discourses on smart city and their agency reached a central role in the outlining of new markets of urban management and transformation. Numerous scholars attempted to disclose the mechanisms of Smart Cities (SC) as a corporate discourse and a tool for disciplinary control. In this contribution, we propose to unveil the processes of future's normalisation enacted by the current SC program and metrics. We argue that this discourse is acting as an extraction of sovereignty through normalised and neoliberal representations, constraining the way we sense, act and think on and with cities. Grounded on actual alternatives proposed and analysed by the emerging field of SC critique, we will try to outline the frame of a new metric of smartness, based on political and spatial imagination that emphasizes on the coupling between a measure and its worth. Then, we will explore a path opened up by the distributed cognition theory (Hutchins 1995; 2000) and the scaffolded mind theory (Sterelny 2010) put in perspective with the understanding of spatiality as performative (Butler 1993;Gregson and Rose 2000; R.Glass and Rose-Redwood 2014). From these theories giving ground to a new definition of intelligence, we will propose a complementary set of dimensions for an alternative metric, opening up new roles and possibilities for renewed spatial imagination and practices.

KEYWORDS

Smart city alternatives; metrics; sociospatial imagination; spatial intelligence; performativity.

INTRODUCTION

Smart cities, intelligent cities, creative territories… The amount of labelling and publications on the topic of urban intelligence is flourishing. Since the emergence of cybernetics and the growing prominence of the use of IT as tools to develop and manage urban spaces, the discourses on SC and their agency reached a central role in the outlining of new markets. Based on an almost unconcealed collusion between the public sector and a military-industrial complex, numerous scholars attempted to disclose the mechanisms of SC as a corporate discourse and a tool for disciplinary control. Under the banner of efficiency and rationality toward a sustainable and resilient future, most of the SC programs are narrowing decision-making processes, enhancing the decline of the political in urban context and disempowering public policies and local populations of their capacity to imagine alternatives.

In this contribution, we intend to unveil how the current metrics and program of SC impose a normalization, standardization even, of the future. We argue that this discourse is acting as an extraction of sovereignty through neoliberal representations, constraining the way we act and think on and with cities. We thus claim the urgency of finding new ways of theorising and measuring urban intelligence.

Grounded on some alternatives proposed by the emerging field of SC critique, we will try to outline the frame of a new metric of smartness, based on political and spatial imagination that emphasizes on the coupling between a measure and its worth. Then, we will explore a path opened up by the distributed cognition theory (Hutchins 1995) and the scaffolded mind theory (Sterelny 2010) put in perspective with the understanding of spatiality as performative (Butler 1990; Gregson and Rose 2000). From these theories giving ground to a new definition of intelligence, we will propose a complementary set of dimensions for an alternative metric, opening up new roles and possibilities for renewed spatial imagination and practices.

1. RE-EVALUATING THE SMARTNESS. PASTS AND PRESENTS OF THE SMART CITY

1.1. Recent evolutions and metrics of the Smart City

Most of the scientific articles on SC notice the lack of clear definitions. This lack originates in a largely self-congratulatory use of the label (Holland 2007), both shaped by a corporate storytelling and the economic need of cities to develop a competitive image (Söderström and Klauser 2004). If it was firstly used by the public sector, after the reorientation of IBM, the term was appropriated by companies in order to gain a 'dominant position in a huge market'.

Smart city developed at the same moment than the *Rise of the Creative Class* (Florida 2002). Interrogating the coincidence, Holland questions the sustainability of smart entrepreneurialism with its associated economic growth and gentrification, as the city is becoming through IT more economically and socially divided; he considers that smartness is exclusive, attracting a certain part of the population and ignoring the welfare of other citizens. To counter this critique that grew in civil society, the corporate discourse mutated in 2010's to drastically include citizens; 'To build a smart city, we need citizens capable of inventing a new world.' (Vanolo 2014, citing, www.barismartcity.it). With this strategy, the SC enrols citizens by force in its fabrication, and imposes them to be 'smart'. Participating in the construction of the SC becomes a moral obligation. In this process of forced *democratization,* a new form of moral and ethics of control are enacted by the participation. Enclosing the field of the political and the means of imagination into a standardized participatory contribution, the SC entered a third phase, exhausting political and spatial imagination.

The metrics of the SC suffer from the same problem of high heterogeneity. According to the purpose of the labelling or ranking, the dimensions and the ontologies of the data vary consequently. As noted by Picon, they all nevertheless share common means and objectives: ecology, sustainability, efficiency and optimization through the use of IT, providing competitive environments. Two techniques are mainly used to measure the degree of smartness: Benchmarking and Modeling (Komninos 2007). We will focus on benchmarking practices as they constitute the main core.

Benchmarking consists in the comparison of cities between each other to learn from the best practices. It permits to understand the weaknesses or strengths of a particular environment, and to work to overcome or rely on them. The role of these rankings is of a huge importance for territories in order to situate themselves in the international competition and to foster economic growth (Giffinger 2010). Territorial Benchmarking is defined as such:

> In all cases the process starts with a definition of benchmarking topics, and goes on to select

> the indicators per topic, followed by data collection, selection of the comparison group, calculation of benchmarks, and interpretation of the results. The scope of the methodology is always the same. We attempt to define the range of variation of performance in any field of activity, the minimum, average, and maximum scores of performance, the distance from the best, and the practices that sustain performances. (Komninos 2007,131)

Even if there is no consensus on metrics, we can note some more influential insights. One of the most representative research is the *Smart-Cities Ranking of medium-sized city*. The aim of the benchmarking is clear, it is to help medium-sized cities to become competitive at international scale in terms of resources, critical mass and organizing capacity. Were selected cities of more than 100.000 inhabitants, with at least one university, already cited in other ranking or with headquarters of a major company. These criteria added with the data availability permitted to rank 70 cities in Europe. According to the literature' review the scientists made, six domains of smartness were identified -smart economy, smart people, smart governance, smart mobility, smart environment, and smart living. Upon these domains, they proposed 74 indicators, themselves regrouped in 31 factors. There is a lot that could be commented on the factors and indicators of Smartness, but we will focus on the Smart people factors, as it is representative of the new radically inclusive strategy.

The diverse dimensions used point at one type of population. Well trained, adaptable to the labour market, flexible and creative, cosmopolite and open-minded, while always voting; the factors clearly indicate which behaviour is right to be smart. Benchmarking practices and dimensions' finding 'are full of values, judgements and deliberate strategies of occlusion' (Kitchin 2016, 52).
Despite lack of evidence of its impact on the population, the authors insist on how this ranking has oriented numerous politics, particularly in the cities included in the ranking. Coupled with the forced enrolment of citizens in the fabrication when implementing corporate SC initiatives, the performativity of such metrics is extended with the use of environmental technologies that 'mobilise urban citizens as operatives within the processing of urban environmental data [...]. Citizens [...] have a set of citizen-like actions at their disposal, enabled by environmental technologies that allow them to be participants within the smart city.' (Gabrys 2014, 41). These metrics and technologies introduce a self-enforced means of regulating the way we act, move, think and perceive in the SC, without the need to directly govern individual practices; the new environment outlines and makes the right behavior emerge by compliance and convergence. In this motion, the rights of the citizen are replaced by choices to be made (Cowley, Joss, and Dayot 2018), and we observe a transformation from inhabitant to consumer and data-producer

Smart People	Level of qualification	Importance as knowledge centre	2006	regional
	Level of qualification	Population qualified at levels 5-6 ISCED	2001	local
	Level of qualification	Language skills	2005	national
	Affinity to life long learning	Book loans per resident	2001	local

	Participation in public life	Participation in voluntary work	2004	national

Figure 1. Dimensions, factor and indicator corresponding to the calculation of Smart People . Giffinger et al. 2007)

in the way people are considered by policy-making (Cardullo and Kitchin 2019).
The metric of SC does not function as a mirror that reflects reality. The dimensions, indicators and factors that permit to rank cities and policies is creating a form of ethic based on algorithm (Söderström 2014; Vanolo 2014), strongly de-politicising the planning decision, indicating what is the good behaviour to adopt. This 'objective reality' based on the city as a set of measurable facts, apparently transparent and non-political deeply modifies the way cities are produced. They are strongly normative as they are shaping governance while influencing decision-making, institutional spending and workers forms of labour (Kitchin et al. 2015).
In this perspective we intend to outline that, through SC' programs, our spatial and political individuation (Simondon 2005) are short-circuited, hindering our capacity to think the articulation of contingent socio-spatial alternatives, from the level of the body (what is a good and smart citizen) to the level of the institution (what is a good and smart university) and policy-maker (what is a good and smart decision). This reality formulated by those metrics and programs presents itself as natural, and thus should be considered as hazardous (Zupancic 2011; Fisher 2009), extending a *scientific* realism to constitute a capitalist realism. Capturing our future (and its markets) by a colonisation of its imaginaries, it is then urgent to find new narratives and alternative figurations of the way IT could be implemented in our environments, and of what could be a SC.

1.2. Alternatives

Nevertheless, some perspectives arise in the need of new ways of theorizing, cases to examine and methodologies for comparative research (Luque and Marvin 2015). Soderstrom and McFarlane (2017) proposed a new framework to define smart urbanism. To do so, they depart from several assumptions for the most shared amongst critical scholars: urban intelligence or SC program should not be primarily associated with new technologies. Secondly, territories and cities of the Global South should also be studied and hypothesized as potential fields for smart urbanism, for the notion not to be north centric and normative. Then, if technology is not the (main) core of Smart Urbanism, knowledge, in all its forms, is the main means of such an approach.
According to the authors, the return of modernist and technocratic approaches of planning in smart urbanism necessitates the use of theories of usable knowledge (Lindblom and Cohen 1979). As such scientific knowledge is inefficient without the encounter with ordinary knowledge, which combination is at the core of an usable one. It demands scientists or companies to first identify the knowledge and use out of the traditional scope of the 'techno-fetichism of smart urbanism discourse' (2017,16), and defined by grounded co-productions, and simultaneously understanding the knowledge forms of the residents. Knowledge and learning are then becoming the critical point of smart urbanism, as the technology implemented should follow the lines of identification and not the inverse. Based on empirical research, this renewed approach of urban intelligence and SC is grounded on the 'place-based, experiential, and largely neglected urban knowledges of residents in precarious contexts' (2017,30), permitting to foresee an inclusive and contributive dimension in the smart urbanism. Also, Barcelona is developing a remarkable counter-model based on digital sovereignty and it has been largely noticed by scholars. Even if some scholars now proposing some alternative visions' state of the art (see Morozov et Bria 2018), no scholars have yet attempted to provide a frame for an alternative metric. We argue that if we develop a demanding and situated metric, the act of measuring could be seen as an occasion to foster inclusion, knowledge in all its forms

and socio-spatial alternatives to the dominant models of SC.

2. GIVING GROUND TO (URBAN) INTELLIGENCE. IN BETWEEN COGNITIVE SCIENCES AND ARCHITECTURE

2.1. Focusing on the value of the metric. Political and Spatial Imagination

One of the key aspects to consider when assessing the adequacy of any given metric regards the relationship between two distinct yet inextricably linked elements of measurement: worth and value. In explaining the main of *Tractatus de mensuris,* by Von Freiberg, Brighenti (2017) argues that establishing 'measures' is a double task: on the one hand, a measure ought to provide a ratio of magnitude [molis], on the other, it ought to provide a ratio of worth [virtus]. Brighenti unsurprisingly argues that the asymmetrical development of magnitude corresponds to the development of modern science. In this process, we seem not only to have lost sight of the crucial link between measure and worth, but also to have fallen into the argument that magnitude is devoid of any inherent valuing apparatus. Such step conceals that measures constitute a directed focus of attention that frames any given phenomenon within a chosen reference (the metric), and value therefore lies at the core of measure, yet not simply as a *product* of measurement.

That a magnitude has its meaning dependant on the broader context that explains the consequences of such a score is evident. However, with the development of synthetic indicators as in the area of SC assessment, the *moral–political* face of measures might not be explicitly rendered. Any magnitude's use is endowed with such dimension because it was devised as a technical tool to *capture* an essentially axiological value and requires, as Brighenti (2017) puts it, to be cast into light – including for instance issues of justice, fairness, competition and reward. Our objective in this paper invites us to tackle Brighenti's question anew: How could a non-formalised notion of value be envisaged in connection to measure?

One of the the key elements that any metric devoted to capture the intelligence of cities cannot circumvent are the main core values of urban settlements: urbanity. Cities have arguably proven in the course of history to be spatial and social devices for the articulation of social diversity, facilitating the birth of societies that respond to completely different logics than those in rural areas (Tonnies, Durkheim 1912). In fact, cities have facilitated the emergence of greater heterogeneity as if they were devices for overcoming determinism and entropy. A particularly interesting and fecund notion that captures the inherent pregnancy of value within the measures of salient forms (here borrowing from Thom 1988), is urbanity, conceived in terms of unbounded or unrestricted communication (Heidegger and Habermas 1984). In this respect, urban living is closely associated with an orientation towards the other through uncertain and undirected means and uncodified forms. Such orientation is best captured in Levinas' notion of "hospitality", as a sensual contact mediated by closeness and physical proximity (Levinas, 1969,172–174). In Jacques Derrida's (1995) work we find an expansion of this ethics towards an "unconditional hospitality": the idea of welcoming differences rather than simply tolerating them.

This view captures the value of urbanity as essentially alien to current metrics of city's smartness. In fact, this necessary ingredient of contingent indeterminacy brings us to one of the key elements and capacities through which an urban society can effectively dissipate entropy: imagination, understood as the virtual manufacturing (in lack of a better term) of virtual horizons of possibilities.

Now, how can such ideal elements of urbanity be materialized or even programmatically rendered into measurable elements? Analysing

this notion of welcoming diversity through a material spatial perspective, it is in the theories and methods of space syntax (Hillier and Hanson 1989; Hillier 1996) where we find a sophisticated method of quantifying how urban morphology contributes to engendering social heterogeneity. Approached from a spatially syntactical perspective (1996), their methods quantify urban centrality through network measures, allowing us to verify to what degree a given tissue favours types of interaction between locals and passers-by that are arguably behind dynamics of societal richness. We bring this as an example of particular instances of molis (measure) where a complex yet specific virtus (value) is evoked, which seems to us more relevant and programmatically useful than most current indicators of smartness.

2.2. Spatiality as a support for thinking. Intelligence, coupling and performativity

Evelyn Tribble's *Cognition in the Globe* (2011) begins with an enigma: `Early modern adult playing companies coped with enormous mnemonic loads, apparently performing up to six different plays a week, with relatively infrequent repetition, all the while learning and mounting a new play more than once a month' (2011, 1). The traditional explanations of such performances were hypothesized the actor's enormous internal cognitive capacities. Nevertheless, it seems that even for extremely trained actors, to learn so rapidly and with no or little rehearsal is almost impossible. Against all odds, she applied the model of distributed cognition's research that takes into account for a full range of factors that could foster, enhance and distribute certain cognitive processes. She led an analysis of the material conditions, of the social structure of the company, of the gestures in the performances, and of the nature of the text, amongst others, within the hypothesis that "no one of these elements, taken alone, has sufficient explanatory power" (2011, 7). What Tribble proved in her book is that the space of the theater and the embodied and collective use of the stage played a tremendous role in the capacity of the actors to memorize and play the piece. Space and its myriad of objects actively participate to a form of collective intelligence.

Going out of the theater, we could argue that urban spaces are supporting cognitive processes. In some, we put memories -cognitive offloading-, and thus, they support processes of remembrance; in other, we may be supported by the environment to learn, discuss, make politics, imagine, invent as much as space help us in navigating or feeding. In this perspective, thinking, without being situated would be an utterly demanding cognitive burden.

This idea is highly supported by recent cognitive science's theories that go further than the distributed cognition hypothesis. The scaffolded mind theory (Sterelny 2010) proposes that 'human cognitive capacities both depend on and have been transformed by environmental resources' (Sterelny 2010, 472). Going from the analysis of Otto's notebook (2010, and others) to emotions and affect (Colombetti 2017), these theories have been used to outline how human cognition can be better understood if we think the mind in its place and in its body (Varela, Thompson, and Rosch 1991; Conein et Jacopin 1994). Nevertheless, 'there is an absence of a serious consideration of spatial dimension of such resources beyond their object like dimension' (Negueruela del Castillo 2017, 163).

Recent theories on performativity have suggested that 'performances do not take place in already existing locations [...] These "stages" do not pre-exist their performances, waiting in some sense to be mapped out by performances; rather, specific performances bring these spaces into being.' (Gregson and Rose 2000, 441). A performance is a 'situated convergence of human and nonhuman elements and force relations through which people, places and things emerge or

become' (Kaiser and Nikiforova 2008, 123), reenactment of sociospatial norms through citational practices (Butler 1990).
Thus, returning to the Globe Theater, we could argue that the spatial intelligence demonstrated by the actors is due to a performative reenactment of the Elizabethan theater; through their practices, the actors, the spectators and all the nonhuman agents are performing a spatiality that supports the actors individual cognitive capacities in the process of remembrance. In this perspective, it seems really important to insist on the fact that the spatiality that support cognitive processes is brought into being by an individual and collective practice; it underlines that there is no form of spatial or urban intelligence that could exist per se, demanding a relational understanding between objects, bodies and virtualities.

2.3. Measuring. Trust reliability and commons

If there is still a lot to investigate on the way urban spaces can support cognitive processes, and consequently, on how we could (if possible) design space that performatively becomes resources for thoughts and actions, we can frame a metric for urban intelligence based on dimensions that permit to measure to which extent a resource is *scaffolding* a cognitive process. In his essay, Sterelny, without pretending to be exhaustive, proposed Trust, *Interchangeability / Individualisation / Entrenchment* and *Individual / Collective*.
o Trust is characterised by the internal assessment of the reliability of the access to the resources, as much as the reliability in the resources in itself. The more the agent has trust in the resources, the less he/she needs to assess insurances against forms of failure
o Interchangeability, Individualisation and Entrenchment are dimensions of the relationships manufactured by skills in time. In order to illustrate the individualisation dimension, Sterelny introduces the example of the professional cooker's knife. His/her knife is necessarily highly individualised; the weight, the sharpness and the balance of the knife are transformed and modified, fitting perfectly in the routine of the cooker. In the same motion, the routine of the cooker, his/her movements are adapted to the balance, the weight and the sharpness of the knife; his/her knife is highly individualised but also highly entrenched in his/her cognitive processes. The gradient is then from interchangeable and standardised resources to individualised and entrenched.
o The Individual and the Collective are gradients integrating the notion of collective as an environmental resources. In this sense, a lot of cognitive processes occurs through collective interaction and not through individual to external resources' interactions. The collective resources are under the scope of intergenerational dynamics, responding to the niche evolution theory (Odling-Smee, Laland, et Feldman 2003), shaped by collective buildings, generational transmissions and modifications.
While trying to apply this model to urban spaces, several elements can be reported. In first place, dimensions of trust and reliability does testimony for a radical ecology; any damaging or spoiling of a resource -urban space- would have for consequences a biais for cognitive processes, addressing in this prospect the growing prominence of the value of care and of the urban as a common good (Harvey 2008; Lefebvre 1974). As already underlined Clark and Chalmers in 1998, 'It may be, for example, that in some cases interfering with someone's environment will have the same moral significance as interfering with their person. And if the view is taken seriously, certain forms of social activity might be reconceived as less akin to communication and action, and as more akin to thought' (1998, 10).
Equally, it emphasizes on the accessibility of urban space as one of the main dimensions of urban intelligence; if a space can not host, he can not support individual and collective intelligence. In continuation, the urban in its

capacity to welcome and host the alterity (Derrida 1995 elaborating on Levinas 1969), to be radically inclusive in unbounded (Habermas 1984) and potentially uncodified ways, captures the essence of a radical and pregnant (Thom 1988) value, or intensity (Brighenti 2019) , which ought to be re-situated in relation to any extensive measure or metric.

The dimensions of interchangeability, Individualisation and entrenchment unveil two other major issues of urban intelligence; hyper-locality and appropriation. Thus, the westernisation' process of cities are phenomenon that does harm the tissues' ability to support certain kinds of cognition, notably highly specialized and situated cognition. This dimension could be measured through the diversity of uses of the spaces and their degree of specialisation. In continuity, appropriation testimonies of an entrenchment of space into uses, and emphasise the role of care and common. The Individual-collective dimension are directly echoing with the accessibility and sovereignty, as means of imagination. Even if we can not postulate an urban intelligence and its metrics *per se*, these dimensions indicate the crucial role of spatialities that support cognitive capacities and ways to frame situated research in the future.

2.4. Chimerical visions for the smart city. Imaginations, figurations and performativity

Proposing this definition of smartness and urban intelligence implies a major shift in current policy-making and SC initiatives. It formulates urban intelligence as a relation between a capacity of the urban to support cognitive processes and an individual and collective process of imagination and entrenchment. As introduced, corporate discourses on SC and IT's implementation are strongly normalizing the future's imaginaries. Spatial imagination is influenced and enacted by representations outlined by powers and the performative re-enactment of social norms and relationships to space (Gregson and Rose 2000). Thus, scholars from geography argue that new technologies are not leading to a re-invention of these practices, but to their reinforcement. Their implementation in cities is reproducing class and gender-relations, racialized urban landscapes, urban inequalities, while serving the interests of corporations and governments (for a resume, see Rose 2017). Sharing this critical stance, Rose underlined that the urban *media manifold* is however producing new posthuman agencies; posthumans 'can reiterate, modulate, and translate those differences, as well as create new forms of differentiation' (2017, 787); namely this same horizon could make emerge alternatives and subversions from the very material seams of its entangled apparatuses.

Re-appropriations of sovereignty and future through imagination are a key hinge toward an integrative and embodied smart urbanism. As such, we contend that the implementation of new technologies into urban planning can be the occasion to create new situated worldviews based on new posthuman agencies and their associated differentiations' forms. Literature on anticipatory techniques have been flourishing in these last decades (Kinsley 2010). Techniques and technologies play a fundamental role in the merging of new figurations. Through the outlining of new figurations of the SC, at the encounter of embodied practices, individual/collective imagination and anticipation, can emerge new performative spatialities (Gillian and Rose 2000) for cognitive processes to be supported by. Along the proposed dimensions for the new metric based on cognitive sciences theories, these chimerical visions, in between bodies, technologies, virtualities and other vibrant matters (Bennett 2010), give ground to a situated, politicized and embodied urban intelligence.

CONCLUSION

In this article, we try to outline in which ways the SC program and its metrics are acting from policy making to bodily scale. We emphasize the diverse forms of rationalism that lie under the implementation of new technologies in urban planning. This reveals how the reality-making process they are based on is fostering an extraction of sovereignty. A review of one of the most influential metrics showed us how SC programs were addressed to a certain kind of population -well-trained, flexible, creative… Coupled with the forced enrollment of citizens in SC programs and the environmental technologies that permit citizens to monitor their own practices, these metrics are giving ground to a new form of ethics whose compliant associated behaviors are emerging from diffuse and indirect strategies of control. From that point, we bring in the point of view of different scholars and projects on possible or realized alternatives to this SC paradigm. They attest to a dynamic and coherent field of critique challenging the corporate perspective. Nevertheless, no alternative metrics have yet been developed. We argue, in regard to former paradigms, that this could be an instrument for democratization and citizen's sovereignty enhancement by establishing and discussing the worth of a ratio in relation to its magnitude. Grounded on insights from cognitive sciences and performativity theory, we propose another definition of spatial, and thus urban, intelligence. Spatiality has been sketched out as a support for cognitive processes, while being itself brought into being by citational practices, opening the path for a relational, situated and embodied definition. From there, we discuss the dimensions assessing to what extent a resource is *scaffolding* (supporting) a cognitive process in the context of urban intelligence, defining six non-exhaustive dimensions: trust, reliability, accessibility, sovereignty, hyper-locality, appropriation. Then we emphasize the importance of new forms of posthuman agencies in the outlining of urban intelligence, as themselves being able to renew and reinvent spatialities of SC. As such, spatial -and political- imagination, as an embodied and collective practice, had been argued as the main mechanism of creating socio-spatial alternatives to the corporate and normalized SC.

It is thus evident that this metric is highly theoretical and has been manufactured in between the secured and comfortable walls of a (Swiss) university. We nevertheless contend that it is from this same locus that should emerge new SC programs and initiatives focused on knowledge-intensive and inclusive territories despite all the scientific crises that universities are going through. It has been for long outlined that the power-knowledge relationships in cities are the core of the re-enactment of inequalities and corporatism (Foucault 1969, 1975), and universities are the center of this distribution. While recognizing the importance of usable and situated knowledge, against systemic and unadapted solutions, institutions should reinvent their role in their own territories and start taking care of their environment. Institutional imagination (Barnett 2013), as an extension of the chimerical imagination we discussed, is one of the major hinges toward an embodied, politicized and inclusive urban intelligence.

PAPER #4.03

SMART DESIGN FOR BICYCLE PARKING STATIONS. A PROPOSAL FOR THE HISTORICAL CENTER OF AREQUIPA, PERU

Gabriela Manchego[a], Cinthya Butrón Revilla[a]
[a]Universidad Nacional de San Agustin de Arequipa, Arequipa, Peru

ABSTRACT

The sustainable development of cities implies a comprehensive urban approach, coupled with this mobility and environmentally friendly modal alternatives, have taken an important focus on citizenship. This research addresses the problem of urban mobility in historic centers recognized as cultural heritage of humanity, where the urban layout has similar characteristics, such as the square grid and orthogonal streets. In addition, in recent years, the increase in the number of motor vehicles and the centrality of activities have generated vehicle pressure and congestion in this urban area. The present study proposes to improve the urban mobility of the historic center of Arequipa - Peru, implementing and promoting the use of bicycles, as a modal alternative and part of a sustainable and intelligent urban mobility policy. This current study proposes a quantitative methodology that combines the use of mobile applications with traditional urban design to intelligently and efficiently plan the location of bicycle parking stations. For the purposes of this proposal, two sources of data were used; the first corresponds to the analysis of geo-positioned data of a group of urban cyclists, who agreed to use a mobile application that identifies itineraries and their potential daily routes, while the second corresponds to the visualization of the proposal of the location of the two-party systems generated through the diagnosis of the case study, based on traditional urban design criteria. This information was contrasted, to finally show as a result the criteria for the efficient location of bike parking using technology, thus concluding, in an efficient proposal for locating and typifying bike parking stations for the historic center of Arequipa.

KEYWORDS

Bicycle parking; sustainable urban mobility; smart mobility; historical center.

INTRODUCTION

Modern societies demand high and varied mobility, and this demand has been gradually overcome by the creation of a transport system that guarantees the safe, flexible and efficient movement of people and goods, something which is framed in the new logic of the paradigm of sustainability. From this standpoint, the sustainable development of cities implies an integral urban approach, where the design of a flexible, safe and efficient transport system contributes to intelligent and sustainable mobility patterns. These patterns are currently relevant due to environmental pressures, the effects of on technology social and economic factors, as well as the correlation between them. Therefore, the exponential growth that this sector has experienced and its foreseeable increase makes the challenge of sustainable urban mobility a strategic priority on a wide-ranging scale.

Sustainable urban mobility and environmentally friendly modal alternatives, such as the modal alternative of the urban bicycle, have taken on greater importance for local residents. In this sense, in recent decades, local governments have increasingly encouraged the use of this modal alternative through various initiatives, such as investments in bicycle infrastructure. In addition to this, the amount of research on this

topic has grown exponentially. Latest studies focus on the infrastructure necessary for the circulation of bicycles, but studies related to the infrastructure for bicycle parking have received limited attention, although the bicycles are parked most of the time. For example, studies in Germany and the United States show a probable underestimation of bicycle parking, although bikes are often parked for up to 23 hours a day. This estimate assumes that cyclists who own parked bicycles do not use bicycles as a modal alternative.

In general, in developing cities, where the use of the bicycle as a modal alternative has increased markedly and the construction of infrastructure to boost it has been increasing its value, various studies have shown that bicycles are mostly parked at the place of residence of the users, in a second position at work and in a third position near public transport stations. On the other hand, in developing cities, where bicycle use has also increased, despite the low investment in infrastructure, said increase has been more notable in the historical centers, where the greater concentration of activity generates pressure and vehicular congestion in its urban layout, which has motivated the use of the bicycle as a modal alternative

Arequipa is an intermediate city, whose foundational grid was declared by UNESCO as Cultural Heritage of Humanity in 2000. There are several Latin American cities, which have historical centers with a reticular pattern, narrow streets, religious facilities, entities public, specialized trade and work centers. The local government has implemented measures for the restriction and regulation of motorized mobility, however, there are few actions to promote non-motorized mobility. This work shows the requirement for innovative methodologies that allow prioritizing actions in favor of infrastructure such as bike parking that increase conservation and urban equity in the heritage management of historic centers.

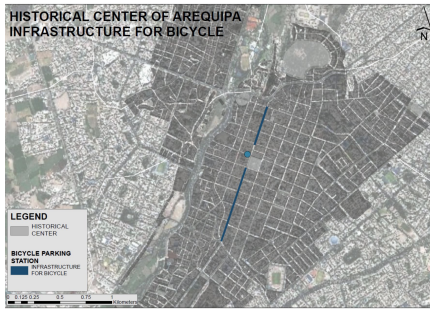

Figure 1. Infrastructure for Bicycle in Historical Center of Arequipa (Manchego 2020)

1. SUSTAINABLE URBAN MOBILITY

Cities feed, change and reproduce in accordance with the mobility of their inhabitants (Joye, Kaufmann, y Bergman 2004). Mobility refers to a series of variables that, unlike transport, which only considers available displacements. Mobility includes the social, political, economic and cultural conditions of those who mobilize. Sustainable urban mobility must be defined based on the existence of a system and transport patterns capable of providing the means and opportunities to cover economic, environmental and social needs efficiently and equitably (Mollinedo 2006). Therefore, the actions to be taken to achieve solutions within the framework of sustainable mobility must consider three factors: First, the social aspect, which must allow the accessibility and generating social equity in the transport systems; second, the ecological aspect, because any such system must protect the environment, reducing the greenhouse gas emissions generated by motorized transport; and third, the economic factor, which must satisfy the economy by promoting development and competitiveness, reducing and regulating the needs of various economic sectors (Muñoz Sotomayor, Betancourt, and Jaramillo Sangurima 2016).

The International Public Transport Union considers that sustainable urban mobility must be based on three "pillars": A land use that incorporates all types of mobility needs, the restriction of the use of private vehicles and the promotion of a system of effective public transport (UITP, 2003). Therefore, adding to the concept of "mobility" the qualification of "sustainable" aims at urban planning that restores the balance between all means of movement (automobile, public transport, walking, cycling), protects the environment and that is articulated to urban development planning and territorial planning (Poole-Fuller 2017). The new concept focuses on the improvement of the mobility and accessibility conditions aiming at a better quality of life for urban citizens, and hence on the pursuit of what is currently called sustainable urban mobility (Costa 2008). In this context, for urban mobility policies to be effective, they must adopt a more integrated approach and make use of technological innovation, promote clean, safe and intelligent transport, economic incentives and changes in legislation. Also, Mobility management consists of soft measures such as awareness, information, communication and marketing campaigns.

The concept of sustainable urban mobility must therefore be understood to be the result of a set of transport and circulation policies that seek to provide broad and democratic access to urban space through the prioritization of non-motorized and collective modes of transport, of effective, socially inclusive and ecologicºally sustainable factors, based on people and not on vehicles (Boareto, 2003, p. 49). As a result, sustainable mobility policies must be integrated from the planning stage, promoting the use of means of clean, safe modes of transport and intelligent, communication awareness and generating changes in legislation as well as the promotion of non-motorized means of transport.

1.1.Smart Mobility

The analysis of urban mobility can be used to understand the behavior of citizens and improve the services, transport and use of urban areas (Ahlers et al. 2016). By adding to the concept of "urban mobility", the qualifier of "sustainable" aspires to an urban planning that restores the balance among all means of displacement (Poole-Fuller 2017) such as cars, public transport, walking and the bicycle. On the other hand, by adding the qualification of "smart", the aim is to articulate these means of displacement transversely (Fu et al. 2016), using technological innovations.

In general, displacement research that contributes with results for studies of sustainable urban mobility has focused on the analysis of the trajectories generated through a smartphone. Paths that are generated by a mobile phone and represented as geographical points on a map are called Smartphone Tracking or Mobile Tracking (Fu et al. 2016). Data obtained from citizens' mobile devices can be used as a basis for urban planning tools. This type of data can facilitate analysis tasks, such as the extraction of human mobility patterns (Wang et al. 2018), or the determination of the urban dynamics of cities. In addition, the data obtained from different users can be visualized simultaneously in a single view, making it possible to identify trajectories or groupings of displacement. In addition, we can analyze the similarity between trajectories, similarity between points within the same grouping, and find anomalous displacements (Senaratne et al. 2018).

Additionally, urban monitoring can be expanded in real time, not only from buses and taxis, but throughout a larger urban area, via an anonymous monitoring platform (Wang et al. 2018). Some studies (Calabrese et al. 2011) have analyzed mobile tracking in order to identify travel or traffic modes in real time, as well as the choice of routes or distribution of products, which has allowed improved urban mobility in terms of vehicular

congestion, especially in spaces where there are conglomeration of activities, such as historical centers or metropolitan areas of large cities. In addition to this, one of the most efficient responses to the problem of vehicular congestion lies in the intensive use of computer systems and telecommunications applied to traffic management. Indeed, the so-called Intelligent Transportation Systems (SIT) have proved to be an efficient support for citizens and for public institutions in the attempt to alleviate the problems of congestion of urban and interurban transport (Seguí Pons and Martinez Reynés 2004), not only helping to improve its mobility but making it more sustainable.

1.2. Mobility in Metropolitan Areas (Historical Centers)

Historical centers, or in the foundational metropolitan centers of cities, especially those that have already grown, have the need to respond to changes in use, customs and a rapidly expanding demography, and in turn need to satisfy commercial, administrative or governmental needs, observing how some colonial mansions or structures have acquired various uses and have become the daily scenario of vehicular and pedestrian, daytime and labor chaos. It is these same centers of the city, subjects of higher density, which brings with its disintegration and greater environmental, visual and auditory pollution, making the deterioration of the city and the lack of attention to important aspects such as protection of history, security and mobility even more evident.

Furthermore, the main problems of mobility and accessibility in the centers of historical cities are the central position, special characteristics of the roads, the concentration in the historical centers of tertiary activities, particularly administrative and commercial, and the presence in these centers of the main historic and heritage buildings. Fig 2. While the main problems generated by road traffic in the historic centers are air pollution, noise pollution, negative visual impacts, the effects on pedestrian movements, streets and squares as places of passage, as well as other effects. (Gutiérrez Puebla and García Palomares 2016). When these conflicts become visible, it is possible that the deterioration of the city center is already advanced, becoming a thorough study of the theory and history of the city's conformation.

Then, to review other cases, models of improvement that facilitate making a diagnosis

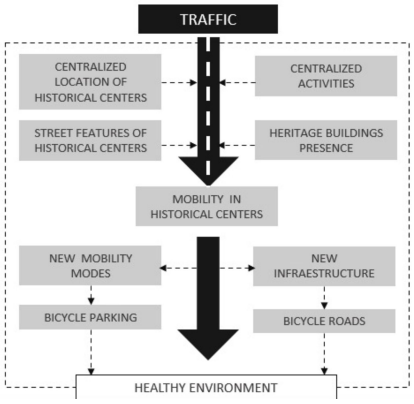

Figure 2. Mobility in Metropolitan Areas (Butrón 2020) based on (Gutiérrez Puebla and García Palomares 2016)

and an appropriation of the problem in order to generate a specific theoretical position of its own (Gutiérrez Puebla and García Palomares 2016). So, if government solutions which take into account the importance of mobility in historical centers are not initially established, the question arises of how to implement tentative strategies to improve not only mobility but also the quality of life of people living in and using this sector. From the point of view of the incorporation of friendly mobility modes, it is the implementation of infrastructure that encourages the use of the bicycle, which would contribute as a tentative strategy to create a healthier environment.

1.3. Biclycle Parking

The location of bicycle parking stations in cities is a challenge from a mobility and urban planning perspective. The development and application of bicycle infrastructure is essential to increased bicycle use. Bicycle parking can protect bicycles from theft, damage and weather. The presence of bicycle parking stations, the comfort and security of the location, its quality and the potential cost facilitates or hinders cycling. Easy-to-access, safe and economical bicycle parking can increase the likelihood of cycling. On the contrary, the absence of an easily accessible, safe and economical bicycle parking stations may deter cycling (Heinen y Buehler 2019). For example, in schools, the availability of parking spaces or stations was found to have a positive effect on cycling to school, but the evidence is mixed, even though the lack of bicycle parking is often mentioned as a reason for not cycling to school (Mackie 2010).

Transportation professionals and urban planners have limited guidance on where parking is best located, how many parking stations are needed and what features this parking should have in terms of quality, proximity and price. The desirable characteristics of bicycle parking facilities may depend on the characteristics of the parking behavior itself (for example, duration and frequency of parking), characteristics of the trip (for example, purpose and distance), the bicycle (value and/or type), location (at home, work, public transport stop) and the user. In addition, these factors can be interrelated. For example, long-distance

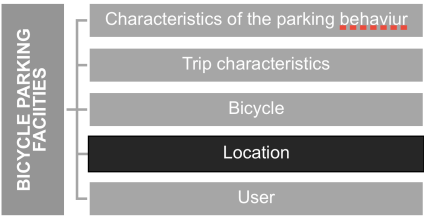

Figure 3. Bicycle Parking Facilities (Manchego 2020) based on (Heinen and Buehler 2019)

trips may require higher quality and more expensive bicycles with greater financial damage in case of theft. Alternatively, people can ride cheaper and lower quality bicycles if the possibility of theft is high (Heinenand and Buehler 2019).

2. MATERIALS AND METHODS

The case study of this research is the historical center of the city of Arequipa, Peru, which is a concentrated urban area of square blocks with narrow, perpendicular streets, stone pavements, and both with both civilian and religious historical buildings. In addition, the city center concentrates important activities and the cycling groups demand more cycling infrastructure. Fig. 1 shows the infrastructure for the existing bicycle, counting only one kilometer of segregated bikeway and one bicycle parking near the main square. It is urgent to prioritize the investment of infrastructure based on evidence that encourages the use of non-motorized modes of travel.

The research presents 2 stages of analysis (Figure 4): Phase 1, a traditional urban analysis and Phase 2 an intelligent analysis of routes

Figure 4. Bicycle Parking Network Stages (Manchego 2020)

of cycling users through the use of a mobile application for the location of a two-station network for the case of study, the historical center of Arequipa (CHA).

The first stage was carried out in the subject Urbanism 1 of the academic period 2018 B, in the School of Architecture at the National University of San Agustin of Arequipa. The students carried out the formative research work entitled "Bike Parking Proposals for the Historical Center of Arequipa", for which they formed work teams to perform an analysis of the components of the urban structure of the historical center of the city of Arequipa, such as activities (land uses), typologies of roads and squares, parks and green areas. In their Tradicional Analysis of the Historical Center of the city of Arequipa, they recognized numerous equipment from administrative, educational, also attracts attention the number of religious equipment. Likewise. Arequipa presents a variety of Parks and places, among the most representative, the Main Square and the San Francisco Place, both spaces around religious equipment. In addition, the Plazoleta San Camilo and the Duamel Park, represent attractive spaces for the location of bicycle parking for the commercial activities they offer in their immediate surroundings. And for another park, in the north zone is the park Selva Alegre, open space for active and passive recreation on weekends. In this Phase the students proposed the location of 15 bi-parking based on traditional urban design.

In the second stage, on the initiative of the local government and the Metropolitan Institute of Planning IMPLA, and supported by the Faculty of Architecture and Urbanism; volunteer urban cycles were called to use a mobile free application data. The cyclists use the application to generated data during a week. Ten urban cyclists were summoned to register their routes through a mobile free application data, to identify potential daily itineraries and routes showing the following. Ten urban cyclists, among women and men, managed to report at least 3 itineraries in the week of experience.

3. RESULTS

The results are visualized on three levels: a macro-level with the general routes of urban cycling at a metropolitan scale (Fig.5); a meso-level where cycling routes in the historic center are displayed (Fig.6); and a micro-level where the public spaces of the historic center and cycle routes are showed (Fig.5). As a result, the contrast between urban cycling routes and cycle parking points are displayed. Those are proposed by a traditional urban design that analyzes: activities and services diagnosis, road directions and open spaces (squares and parks) of Arequipa`s Historic Center to find its strategic location.

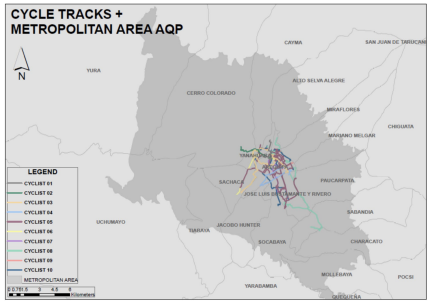

Figure 5. Macro scale. Cycle tracks and metropolitan area of Arequipa (Manchego and Butrón 2020)

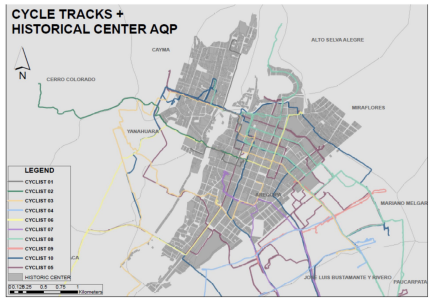

Figure 6. Meso scale. Cycle tracks and historical center of Arequipa (Manchego and Butrón 2020)

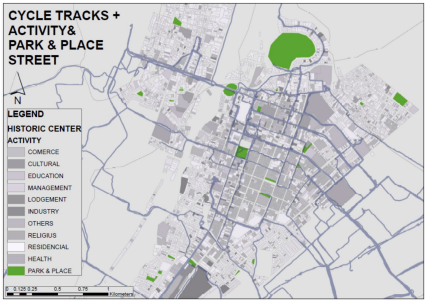

Figure 7. Micro Scale: Cycle tracks and activities of historical center of Arequipa (Manchego and Butrón 2020)

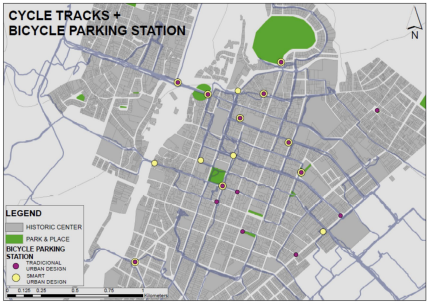

Figure 8. Proposal of Bicycle Parking Station (Manchego and Butrón 2020)

The intelligent analysis shows the real demand of urban cyclists, on the macro scale (Fig. 5) it indicates that the trips are made in the metropolitan area and that in no case do they exceed 5 km in distance. Also, all trips have origin, destination or passage through the historic area. On the micro scale (Fig. 7), it is shown that the routes that cyclists choose to travel through the historical center, is the north zone and displacements in the east-west direction. It can be inferred, the preference of urban cyclists for streets with mixed uses.

3.1. Advantages of smart analysis

As a result, the contrast between urban cycling routes and cycle parking points are displayed. Those are proposed by a traditional urban design that analyzes: activities and services diagnosis, road directions and open spaces (squares and parks) of Arequipa`s historical center to find its strategic location. This work shows the need for cycling infrastructure based on real demand, necessary to enhance this mode of travel.

The combination of the two data sources, the geo-positioned routes of urban cyclists and the preliminary

proposal for the location of the whereabouts are showed at Figure 8. The traditional proposal of location of the bike parking stations have 15 locations and the smart analysis proposal raises 14. There are 9 locations that correspond to both analyzes, however, it is observed that 6 stations proposed in the initial phase do not correspond to the demand of the urban cyclist tracks. In addition, due to the registered tracks, 5 new locations are proposed, completing the proposed bike parking for the historical center of Arequipa.

CONCLUSION

The actions to be taken to achieve solutions within the framework of sustainable urban mobility, are specified in three factors, the social, economic and ecological factors, which in their analysis work must have the technological component in an integral way. Also, of the three factors plus literature also proposes three pillars, which from a traditional urban design, are implemented daily in the different urban plans and manage, however it has not been proposed that these three pillars, which are, the use of land, the promotion of public transport and the decrease in the use of the car, link the modal capacity of the city in a transversal way, taking into account more

options of modes of transport the citizen has greater freedom to mobilize.

This research evidences the importance of the data obtained from the mobile devices of citizens and its relevance as a tool for urban planning and design. From the perspective of the use, analysis and management of citizen displacement data, the literature is corroborated, stating that the use of these can facilitate analysis tasks and decision making in planning, as well as in the extraction of patterns of human mobility or the determination of urban dynamics of cities. In addition, the data obtained from different users allow us to identify trajectories or groupings of displacements that not only link us to determine displacement patterns, but also grouping of anomalous displacements.

The analysis of results allows to detect that urban mobility can be used to understand the behavior of citizens and improve the services, transport and use of urban areas, as is the case of the proposal of the location of the bicycle parking stations. It may have concluded in a traditional urban design, but when using technology, the smart urban design proposal is made, which finally allows us to safely discard some stations where cyclists do not travel frequently. Also, the result, shows the importance of real-time urban monitoring not only motorized vehicles such as public transport, but of friendly transport modes, which allow to implement or improve urban infrastructure in this case, cyclist infrastructure like bicycle parking station, especially in spaces with particular urban structures of historical value.

ACKNOWLEDGEMENTS

We want to thank to the Faculty of Architecture and Urbanism of the National University of San Agustin of Arequipa.

PAPER #4.04

A BIOMIMETIC RESEARCH ON HOW CITIES CAN MIMIC FORESTS TO BECOME SUSTAINABLE AND SMART

Aliye Rahşan Karabetça[a]
[a]İstanbul Kültür University, İstanbul, Turkey

ABSTRACT

In nature, everything is functional to each other. Every single organism supports the other either with a symbiotic relationship or in terms of form and function. For instance, some trees shed their leaves to the ground to prepare themselves for harsh winter conditions and also to create nutrition for microorganisms and fungus under the surface. This kind of interaction with nature could lead architects to develop better solutions to create better built environments; this is the main objective of this paper. The paper aims to clarify and prove that nature is the greatest mentor and can teach humanity many solutions about designing smart cities. There is a new and powerful way of seeking solutions in nature; biomimicry. In this context, using biomimicry as a design strategy is the methodology of this study. Biomimicry is used as a design approach to reach examples in nature by filtering them with biology. These examples are considered to be scientific fields for researching and understanding the structural strength, bioclimatic properties, functional morphology and other features of forests. They are explained to identify forests and provide resilient solutions for developing smart cities. Outcomes of this paper aim to scientifically state that forests are naturally sustainable environments which are the greatest examples for smart cities. When they unite, they can create the most suitable living environments for all living organisms. Several conceptual ideas and methods are suggested based on the biomimetic design approach to make the argument clear and more understandable.

KEYWORDS

Resiliency; biomimicry; smart cities; forests; architecture.

INTRODUCTION

Since the Industrial Revolution, cities were created without considering nature, such as surrounding environments, weather conditions, oceans, natural resources, forests, etc. This led humans to become incautiously independent, unaware of the natural world, and put themselves at the top of the life cycle. Thus, today's cities have become incapable of supporting massive population growth (URL1). Considering that environmental pollution, carbon emission, energy consumption, damage to nonrenewable resources are increasing very rapidly. Sets of precise and sustainable solutions should be developed to stop this catastrophe. How can this problem be reversed? What can be done? There are some ways and approaches designers consulted to look for better ideas in the past but very few looked at nature. As Einstein once said, looking into nature helps humans to understand everything better. What one should do to create sustainable cities is to look at nature for solutions. Otherwise, building cities with similar methods and expecting different results is just a hopeless effort. Humanity needs to build environments that function like forests; resilient, generous, recycling, energy-efficient, aesthetic, etc.

This paper aims to emphasize the importance of using biomimicry and biology to reveal functions and solutions a forest can offer

for a sustainable city design. Designing built environments that function like these ecosystems can be possible with the biomimetic design approach. It is a scientific field that works with different disciplines, mainly biology. Thus, multidisciplinary collaboration is a must. Biomimicry is a new field of science that deals with transferring nature's genius into human-made designs. It leads and guides designers to use principles and strategies of functions in nature to solve human challenges. It is a broad and powerful field and offers nature's endless solutions for every part of the built environment.

Forests live as large groups of trees. They can be counted as the biggest built environments of nature. They are the largest ecosystems which differ from each other according to their species, locations and regions containing thousands of microecosystems within them. Every single member of this ecosystem; mainly trees, when they come together, they create the most sustainable, suitable and resilient living environments for other organisms. For example, a dead tree trunk can manage water consumption for living trees even by standing still that provides a useful service (Wohlleben, 2016). This is how trees embrace and give life to thousands of different life forms; fungi, woodpeckers, beetles, leaf cutters, ants, butterflies, giant trees, etc. The safety and lives of these organisms depend on the strength and durability of each tree in the forest. Therefore, they are well designed, structurally strong, durable, resilient and aesthetic.

Forests are part of a biome that is part of a sustaining biosphere (Benyus, 2014). Their contributions to humans' lives cannot be ignored or be underestimated. Humans cannot exist without forests, but forests can. They are natural air filters. They breathe in the carbon dioxide we produce and breathe it out as oxygen for us to survive which is called photosynthesis. So, why not buildings photosynthesize like trees to eliminate the carbon footprint?

The following must be considered: if a city functions as a forest, then local and non-renewable resources will be conserved. The main requirement for cities to be sustainable and smart is to understand how forests work and incorporate them into humans' lives.

1. NATURE CAN PROVIDE SOLUTIONS VIA BIOMIMICRY

Constructing sustainable buildings with technology is solely possible if the technology considers nature as the design mentor. To follow nature's pathway of designing means searching nature's sustainable design ideas to develop innovative technologies and applying these ideas into humans' lives in the most suitable and appropriate ways. Hereby, design challenges such as pollution in cities, energy loss, climate and structural equipment, etc. which have a large impact on the increment of carbon footprint, would be improved and would make the greatest contribution to the development of smart cities. The fundamental principle of these studies is to accept the biomimetic design approach as the major design guide. During this stage, biology is the first discipline to be considered as a fundamental supporter. Besides, it is highly possible to derive healthy and accurate data by applying biomimicry as a design criterion into the design stage to create a prototype that would be tested in pilot regions.

There are some concrete examples of this process proving that biomimicry can change the design and its results. One of them is the East Gate Building in Harare, Zimbabwe (Fig.1). This building is one of the original biomimetic designs. The inspirational organisms are termites and their mound. Cities created with these kinds of designs could decrease and perhaps eliminate the negative impacts of urbanization. According to research, the world is urbanizing rapidly, and cities will be tripled in size by 2030 (URL 2). The research also states that the need for smart and sustainable cities

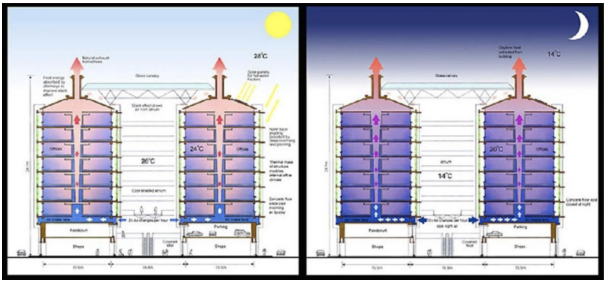

Figure 1. (a) East Gate building designed by Mick Pearce and (b) termite mound. Sources: (URL 3).

is overriding. This is why the design of cities should be based on principles that nature has developed and tested.

There is another example that is not designed with the biomimetic design approach but still a promising building example for designing a sustainable city, Bosco Verticale in Milan. It is considered as pilot project of a new generation of sustainable buildings (URL 4). These buildings were designed in collaboration with ethologists and botanists to develop the botanical components. Two towers have some benefits for the city. For instance, plant-based shields on facades do not reflect sun rays that decrease solar radiation that helps to reduce the use of mechanical ventilation systems (URL4). As a result, forestation on facades can indirectly decrease their carbon footprint.

However, such buildings are considered green buildings where the biophilic design approach is involved more than biomimicry, still very much needed for sustainable cities (Fig. 2). Using biomimicry in architecture not only as a source of form but also as a design strategy comprises more sustainable designs; for example, shapes of nature may provide solutions to architects and engineers for designing resilient structures. On the other hand, many different organisms may offer solutions for energy efficiency, anti-reflective surfaces, self-cleaning paints, or water collecting facades (Karabetça, A.R.,2015). Buildings designed with these ideas would have different consequences.

Figure 2. Bosco Verticale (Vertical Forest) in Milan, Italy (URL 4).

1.1. How do forests work?

It is critical to consider nature while designing. Nature allows nothing to go to waste; it recycles water, soil, carbon, and air to sustain all habitats. A responsible and sustainable architecture lies underneath this logic. Nowadays, the relation between architecture and nature is at its peak point due to the environmental crisis. Because of this peak point, seeking a responsible architecture became vital. Consequently, several kinds of researches on how to establish built environments mimicking

forests have been made throughout the last decades.

Forests are incredibly sustainable and smart environments. They are capable of many things. They have many functions to survive the worst. They can absorb water from clouds, and they can help retain water onsite by interacting with other species. Fallen trees can stabilize and enrich the soil; they inhabit thousands of species working and living in collaboration. There are thousands of valuable functions that forests provide for themselves and for the other living organisms within. Trees in forests such as firs, spruce, beeches or oaks, support each other due to tough/beneficial conditions. They help their young to grow with full nutrients mainly sugar provided from fungus under the soil through their roots. Roots are the most important parts of forests, they are considered as the brain of forests; they provide a very powerful intercommunication with other species (Wohlleben, 2016). On the other hand, every forest survives according to the living conditions of that region. Redwood forests in California have different habits but spruce forests in Europe are quite different then redwoods. For example, Alders can survive in wetlands/marsh areas, but beech cannot. It's because beeches cannot grow in wetlands due to their physical conditions. The forest ecosystem has a sensitive balance. Each member of the forest has functions that contribute to others' lives (Wohlleben, 2016). However, conditions in the forest are not very easy. Each species tries to survive and takes what it needs from others. All of them are brutal and there is only one reason why the system does not collapse; there are protective methods against those who ask for more than their needs (Wohlleben, 2016). It is one of the important reasons why humans face too many problems; we take more than we need, and there is not a protective method against this behavior. The consequences of this greed are underwhelming.

Forests recycle everything cities do not, forests do not produce waste, cities do, and it is mostly not recyclable. Although there are some fights within everything, forests work in harmony where others get benefit from it. Forests are restorative, regenerative, sustainable, and life-giving. Nature uses a minimum amount of energy to complete the process when producing, there are no leftovers. It makes everything as it requires to be when it needs to be (Harman, 2013).

2. SUSTAINABLE SMART CITIES THAT MIMIC FORESTS

A city can be smart but not sustainable that today's most cities are alike. Cities, in general, are growing upwards and outwards like forests. However, they are not the same. One grows upwards due to photosynthesis, which is vital for the sustainability of the forest, and other grows for people to gain benefits of clustered urban life that outweigh the liabilities of living in a densely populated place called economy and business (URL 5). These two targets are essential. But people do not have to live in a city where there are too many adverse effects for sustaining their lives; traffic, air and environmental pollution, energy loss, large carbon footprints, buildings that spread radiation, and carcinogen, etc. Cities are not only growing vertically but also growing horizontally, and doing them at the same time at recorded levels creates deliberate consequences for land use, environment, and planet earth (URL 2). When cities filled with green, does it mean they are sustainable and/or smart? In many cases, they are not. Because turning the city into green helps to reduce radiation of sunlight that also helps to reduce energy consumption. If cities could be designed with ideas emulated from nature, they would not only reduce energy consumption but would reduce water consumption, collect water, store water, create better circulation

No	Name of the city	Location	Design features
1.	Smart Forest City Cancun by Stefano Boeri Architects	Cancun, Mexico	To inhabit 130.000 people with 7.500.000 plants Completely food and energy self-sufficient. (URL7)
2.	Liuzhou Forest City	Liuzhou, China	absorb 116.000 tons of carbon dioxide, solar panels, self-sufficient energy, green roofs and facades
3.	Vincent Callebaut Smart City	Paris, France	bio-air condition the urban heat island phenomenon, depolluting, thermodynamic green towers, etc.

Table 1. Examples of Forest Like Cities (Table created by the Author).

systems, habitable indoors and outdoors, etc.

William Mcdonough known as green architect stated as follows *"…buildings conceived as mass-produced machines impoverish cultural diversity and leave their inhabitants cut-off from the wonders and delights of nature* (URL 6). Based on this statement, it can be said that forests that create considerable parts of nature are fundamental for the sake of the whole world. Several cities that attempted to be designed following some principles of forests (Table 1). However, these promising ideas are still immature, designed with conventional construction systems, and nearly all of them focused on energy saving.

Figure 3. Smart Forest City Cancun, Mexico. Source: (URL 7).

Smart Forest City Cancun, Mexico:

Boeri designed a city that can inhabit millions of plants and 130000 people in an area of 557 hectares (Fig. 3).

The city is designed mainly with green plantation and landscaping. Also, there is going to be internal electric and semi-automatic mobility that aims to reduce the carbon footprint of the city. City plans to absorb 116.000 tons of carbon dioxide. The amount of green and the number of buildings is almost equal to each other which provides a significant balance. There are solar panels for self-sufficient energy, green roofs, and facades for reducing solar radiation enabling less energy use. Agricultural fields for food are other important features of the design (URL 7).

However, there aren't any biomimetic design approaches in this design which are based on emulating/transferring functions of a forest rather than integrating trees and plants into a city.

Liuzhou Forest City, China:

Liuzhou Forest City (Fig. 4) is also designed by the same architect as the previous example. There will be 40.000 trees and more than a million plants which will allow the reduction of carbon dioxide emissions in the city. All buildings will be covered with plants accommodating more than 30.000 inhabitants. All buildings designed in this city are much alike Bosco Verticale in Milan which was also designed by Boeri. The city has similar characteristics to

the previous example explained above. Solar panels on roofs, green roofs and facades, zero impact, an autonomous urban agglomeration, geothermal energy for heating interiors, electric train railway. According to the designer, the environmental benefits of such design are highly obvious. Vegetation for better air quality which aims to absorb 57 tons of carbon dioxide and produce 900 tones of oxygen per year. Other benefits are avoiding the use of cement, blocking the city to cluster outside by keeping buildings within the forest, safeguarding forests, and conserving biodiversity (URL8).

Figure 4. Liuzhou Forest City, China designed by Stefano Boeri is expected to be constructed in 2020. Source: (URL 8)

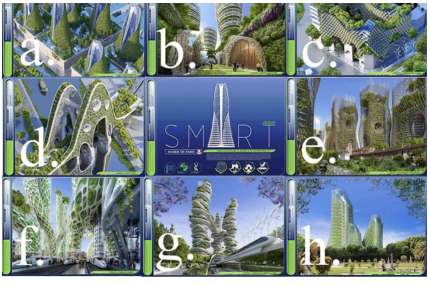

Figure 5. Eight prototypes of energy plus towers for Paris 2050 designed by Vincent Callebaut. Source: www.vincentcallebaut.org (URL 9)

Vincent Callebaut Smart City Paris 2050, France:

Vincent Callebaut is another green architect who has concerns about nature. He created many city designs that contain many plantations for some other countries. But for Paris, he has eight prototypes of energy-plus towers eco-conceived to fight against climate change (Fig. 5) (URL 9).

These are *a. mountain towers* that are green, solar, and hydrodynamic towers which bio-air condition the urban heat island effect, *b. antismog towers* that create an ecologic corridor in the center of Paris, *c. honeycomb towers* that are housing buildings that develop energy solidarity corporation, *d. bridge towers* that inhabit amphibian bridging across the Seine river, *e. bamboo nest towers* that are thermodynamic green towers wrapped by a bamboo wired mesh of vertical gardens, *f. farmscrapers towers* is a vertical urban farm returning the countryside to the city, *g.mangrove towers* that are photosensitive and rooted on piezo-electrical station platforms and *h. photosynthesis towers* that have algae powered bio-facades (URL 9).

Although these designs do not include any function emulated from nature, they are still considered as smart cities. The main idea is to conserve and save energy, decrease pollution, decrease deforestation, and decarbonization which is caused by planting too many plants and trees on tall buildings. However, unexpected consequences of this type of design may result in negative ways, such as ventilation problems of materials of buildings, durability against roots and infestation, weather changes in the cities due to much planting and forestation, high risk of fire, etc. Building such cities in small scales in pilot lands to record expected and unexpected results can be suggested as an option. Meanwhile, biomimetic designs and prototypes can be developed for further achievements. As can be understood from the study, collaborative laboratory studies

must be generated to provide accurate and usable systems.
Not all city forms can do the work the same. They may provide different consequences concerning different countries, locations, weather conditions, topography, and human culture, etc.

2.1. What can be achieved in terms of energy, structure and recycling (zero waste) behaviors of forests?

Biomimetics is a field of science that defines itself consistently with the technical implementation and application of structural systems, emulations, and biological design systems. Although emulating systems is a way of the design approach, there are some points to consider; designers must be cautious during the translation of living systems into artificial human life where everything is mechanic and should not expect the impossible. The other one is to do analog research, such as the ventilation system of Eastgate building based on termites is an analogous system (Pohl and Nachtingall 2015).
Forests have many design features that can be analogous. In this paper, energy and water efficiency, structural behavior, and recycling are studied briefly to reveal some proposals. Here are some examples based on three fundamental features of forests that can inspire innovation in designing and planning a sustainable city (see Table. 2).
Energy and water efficiency (considering that energy consumption is the primary cause of global warming and pollution)
Energy efficiency is one of the primary functions of forests. Forests save energy when they grow, shed their leaves during harsh weather conditions to eliminate energy and water use. Water is vital for the survival of forests. They have specific behavior that saves water for all inhabitants. For example, pine needles divide raindrops into smaller droplets to create a pastoral forest fog that becomes a water source for many organisms (URL11). The density of branches and leaves of different species in the forest creates calm air that prevents water from evaporating for saving water (Wohlleben, 2016). This can inspire façade designers to develop a new generation of façades that could collect water and save energy. Buildings' roofs can be

Figure 6. Roots of a tree from an old-growth forest in Trabzon holding the ground very strongly. Source: (Photo archive of the Author)

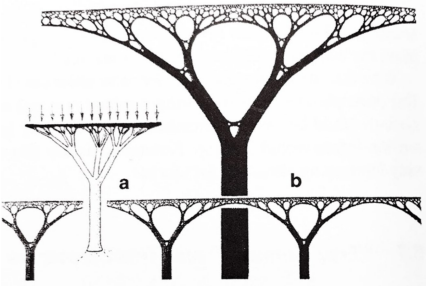

Figure 7. Lightweight tree columns for spanning structures. Source: (Pohl and Nachtingall 2015)

Major functions of forests	What can be achieved with it
*Forests absorb water from clouds	*Water collecting facades
*Interaction with other species to help retain water onsite	*Roads and pathways connected to each other collect and keep the water in specific points
*Everything in forest is recyclable	*Waste management upcycling-recycling, convertible, changeable products, responsive buildings, etc.
*Communication with other species of trees trough roots and fungus	*Protection, resiliency of users, information sharing and gathering for safer and green traffic
*Trees in forest cooperate with other organisms	*Sharing energy and water with other facilities, regions, buildings roads generating energy, collecting solar power by using other building facades, etc.
*Trees adapt to changing conditions	*Buildings that can adapt to changing environmental conditions, responsive architecture is possible.
*Trees are strong enough to resist earthquakes and hurricanes	*Columnar supports, tree columns, resilient structural bearing systems emulating root systems.

Table 2. Some major functions and design ideas that could be achieved and developed Source: www.asknature.org (URL10) (Proposals by the Author)

designed connected like tree crowns to collect rainwater and to avoid evaporation (Fig.6).

Structural behavior

Structures such as the adhesion of a tree to the ground (Fig.6), the body of a tree, and its resistance against strong winds can be an essential structural solution method precisely for the cities on the earthquake lines. Trees grow according to the distribution of total constant stress and thus avoid peaks of tension at roots and forks. During this growth, trees add material specifically in tensioned parts, such as branches and roots (Gruber, 2011). This makes brunches and roots durable and resilient against unexpected storms and wind loads. So, it is possible to design structures functioning like tree trunks, roots, and branches. There are some examples of such systems: lightweight tree columns, root systems for resilient building design specifically located on earthquake lines (Fig. 7). The roots of trees can inspire designers to create foundations for buildings. In rain forests where the soil is shallow and cannot provide the same resistance as others in temperate climates, trees have evolved buttresses that can show greater resistance to larger loads (Pawlyn, 2011). These kinds of structural designs would help to resist against devastating earthquakes.

Recycling

Nature produces what it needs and recycles everything. There is no waste; one's trash is other's nutrients; one's carbon dioxide is another's sugar; dead tree trunk is a nutrient provider for young trees. Life in nature depends on this cycle. As the number of live and dead trees in the forest increases, the humus layer on the ground becomes very thick, as a result, more water is stored in the total forest mass (Wohlleben, 2016). It means even the dead trees have a very high and privilege benefit for all living organisms in the forest. The question is "How can this system be transferred into city planning?" or "Is it possible to design a zero-waste city?". The answer is not discovered yet. However, a prototype pilot region can be designed and built to record results for future generations. A smart and sustainable city, which has waste management similar to forest, convertible or changeable materials, responsible systems that work with recyclable materials, is possible.

There are many organisms in the forests that can inspire designers. Table 2 shows some other examples that could be achieved. These proposals are only representing possible solutions that could inspire designers. Laboratory studies should be achieved to record and prove the results.

CONCLUSION

As a result, forests work very much different from built environments. Their main duty is to survive with the least amount of materials, effort, and energy to achieve the required job, to survive and recreate itself without giving any harm to its foundational ecosystem. After 3.8 billion years of experience, nature has found out effective ways of surviving challenges after many errors, attempts, and experimentations. Now it is designers' time to look at nature's endless library for elegant and efficient methodologies free of charge for those who are on the right path of research (Harman, 2013).

By 2025, biomimicry is expected to impact a considerable percentage of manufacturing, waste management, architecture, and other services such as technology and robotics that are related to remediation and innovation. Technology and nature are two facts that form parts of a continuous process. Biomimicry guides designers to develop a continuous process. Sustainable and smart cities are possible yet difficult to achieve, but not impossible. Biomimicry has the potential ways of using nature's genius to develop ideas and solutions. Studying nature provides opportunities. However, turning these opportunities into rewarding solutions depends on profound laboratory work and collaboration with other disciplines. A special research center is required for such works to be supported and completed. Can a city be both sustainable and smart? What would it take for a city to function as elegantly as a forest? The answers to such questions could be given if serious researches would done.

Nature is always ready to share its endless secrets with humans to achieve sustainability in architecture. It consistently uses energy more effectively and efficiently; its production system and materials are much more innocent and harmless than the materials produced by the human that significantly increases environmental pollution and energy loss.

PAPER #4.05

AGGREGATED DATA MANAGEMENT AND BUSINESS MODEL IN DESIGNING POSITIVE ENERGY DISTRICTS

Paolo Civiero[a], Jaume Salom[a], Jordi Pascual[a]
[a]IREC Catalonia Institute for Energy Research, Sant Adrià de Besòs, Barcelona, Spain

ABSTRACT

The paper aims to describe the results of the on-going EU founded research titled "PEDRERA Positive energy districts renovation model" which scope is to design a tool able to support smart district renovation programmes. The key goal of the model is to facilitate the multiple stakeholders' engagement in large-scale renovation actions according a Positive Energy District (PED) vision, and to predict the sustainability and positive outcomes of distinct renovation scenarios. One of the main barriers to reach this goal is the lack of integration of disaggregated information coming from heterogeneous data sources. The PEDRERA model means to build trust in the business opportunities by allowing better support to decision-making and impact assessment in order to understand and manage both the complexity of financing renewal processes at district scale and the interests of each stakeholder.
The paper addresses these challenges and will examine how data sources from different domains could be adopted in PED design once the information is aggregated, systematized and addressed to specific key performance indicators. Furthermore, the customized model will run data through a special wizard able to filter input data which are displayed and shared on a GIS platform.
According to this approach, the novel tool will be able to (1) guide and support the entire retrofit process according different issues, (2) meet the most relevant requirements from each stakeholder by prioritizing and designing energy efficient measures based on a reliable business model, and (3) help on willing sustainable energy communities to come.

KEYWORDS

Positive energy districts; smart city; sustainable energy communities; data aggregation; interoperability.

INTRODUCTION

In 2050, the built environment should be nearly carbon neutral but it's still not fully clear how to achieve a sustainability scalable model coherently with the SDGs (Sustainable Development Goals) of UN[1] . Considering that the building stock constitutes the largest single energy consumer in the EU, and that the value of the European mortgage market is equal to 53% of EU's GDP, there is huge potential to bridge financial innovation and the energy efficiency (EE) world and to unlock the benefits of mortgage financing to support EE to the benefit of all[2].
The revised Directive 2018/844/EU introduces targeted amendments aimed at mobilizing of investments toward decarbonized cities and accelerating the cost-effective renovation at the neighborhood and district scale[3] which means a transition to an intelligent system based on: (a) Cluster of geo-referenced Energy-efficient Interactive Buildings (EeIB) [Arbizzani et al. 2014]; (b) Interoperability and integration of data; (c) Feasibility of

[1] 2050 Energy Strategy, European Commission https://ec.europa.eu/energy/en/topics/energy-strategy-and-energy-union/2050-energy-strategy.
[2] Source: Energy efficient Mortgages Action Plan. https://cordis.europa.eu/project/id/746205.
[3] Source: ZEBRA 2020 www.zebra-monitoring.enerdata.eu/

technical and economic scenarios enabled by economies of scale.
In this contribution, we present the approach of the PEDRERA (Positive Energy District Renovation Model) project whose main goal is to design an innovative energy large-scale renovation model able to accelerate the urban transition towards Positive Energy Districts (PEDs) by collecting and gathering available data from multiple domains and demonstrating the feasibility and opportunities of renovation projects at large scale. The design of energy efficient retrofitting projects, in this case at district scale, is a challenging problem that requires a spatial model, a multi-scale and multidomain evaluation, a constant interaction among stakeholders, and other not-directly related to energy information that will be useful to formulate predictive and feasible business model adherent to the purpose. Retrofits of this scale will require the ongoing management of a well-financed, data-driven, and strategically-targeted program.

1. LITERATURE REVIEW

Recent developments in the fields of Internet of Things (IoT), Artificial Intelligence (IA) and new city modeling, are driving and supporting the development of smart sustainable cities where Positive Energy Blocks (PEBs) and Positive Energy Districts (PEDs) represent crucial nodes of such cities, due to their capability in achieving a positive average annual energy balance[4]. When the positive energy balance assessment moves from a single building to a group of buildings at district level, new considerations are needed in terms of integrating urban and energy planning and evaluating the overall energy performance (according to different choice of assessment methods defined in the modular and overarching framework of the ISO 52000). Thus, in that case of district scale, the assessment boundaries are strictly related to the attributes of the assessed cluster of buildings, as also the mutual interactions between each other, regarding to the common technical building systems and the delivered energies carriers.
Even if an accurate concept of PED is still under discussion, PEDs are widely considered as mixed-use energy-efficient districts that have net zero carbon dioxide (CO2) emissions and actively manage an annual local surplus production of renewable energy (RES). They require interaction and integration between buildings, the users and the regional energy, mobility and ICT system, while ensuring social, economic and environmental sustainability for current and future generations.
An extensive range of different approaches and actions are currently focused on the PEDs definition and the implementation of PEDs strategy for energy transition and the climate mitigation in the urban context, among which:
- PED concept integration in the SET Plan Action 3.2 implementation plan[5];
- Consultations with city representatives and other urban stakeholders in various countries, in particular collecting input under the PED Programme[6];
- European Energy Research Alliance (EERA) Joint Programme on Smart Cities (JPSC) and the Smart Cities Information System (SCIS)[7] support for the PED definition and a pathway towards PED in Europe.

[4] The concept of PEB is now fully recognised by the European Commission even if PEB is defined by the EU as a group of at least three connected neighbouring buildings (new, retro-fitted or a combination of both) producing on a yearly basis more primary energy than what they use. The ISO 52000-1:2017 establishes a systematic, comprehensive and modular structure for assessing the energy performance of new and existing buildings (EPB) in a holistic way.
[5] The Strategic Energy Technology (SET) Plan Implementation Working Group 3.2 Programme "Positive Energy Districts and Neighbourhoods for Sustainable Urban Development".
[6] Among other, JPI Urban Europe AGORA is focused on JPI Urban Europe's Stakeholder Involvement Platform which aims at creating the space to meet and exchange for urban actors.
[7] The EERA JPSC aims to accelerate new energy technology development by cooperation on pan-European programmes and is directly involved in the SET PLAN TWG 3.2. The SCIS is a platform that brings together different type of stakeholders from across Europe to exchange data, experience and know-how and to collaborate on the creation of smart cities and an energy-efficient urban environment.

- National initiatives supporting R+D+I on PEDs as the Spanish Technological Platform for Energy Efficiency (PTEee)[8].

The draft definition of PED developed by the EERA JPSC working group, is the result of reviewing and considering definitions from current projects and programmes and bringing in particular R&I perspective - such as the "Booklet of Positive Energy Districts in Europe"[9] , the PED Programme Cities Workshop, H2020 Lighthouse projects - and consultations of stakeholders on national and European levels.

Smart districts modeling methods

In this transition process toward efficient and sustainable cities, it is well known that data collection will drive planning investment policies on urban domain. Availability of widely monitored and shared data is one of the key aspects of smart cities, and would represents a barrier to sustainable urban development in the next future. The chance to access information and to manage data depends mainly by the availability of open data according specific departments at regional or local level, but also refers by the ability to aggregate data and exploit this information according user' scope. Furthermore, in order to achieve long term urban renovation processes, innovative monitoring and managing smart decision-support tools are needed to gain economies of scale through a demand-aggregation approach.

In many case the workflows can be developed for whole cities and neighborhoods to generate urban massive models from available datasets such as GIS and CityGML [Ascione et al., 2011]. Furthermore many district tools support the calculation of the yearly energy balance according different categories depending on the scope, scale and purpose of the work at hand[10]. Such information includes usage and conditioning profiles, the number of occupants, schedules, equipment power density, lighting and passive and active systems and their control strategies. The development of Urban-Scale Energy Modelling (USEM) at district or city level is today the goal of many research groups due to the increased interest in applications such as new strategies for city energy supply/ demand, urban development planning, or distribution networks stability. USEM faces a complex set of multi-domain problems e.g. related to multiscale heat and mass transfer phenomena (climatology, building physics, infrastructure requirements, etc.) as well as land use, transportation, urban morphology, local availability of energy resources, or user behaviour [Sola et al. 2019, Letellier-Duchesne et al. 2018].

The first step, which consist in the collection of information for creating spatial models needs, is one of the most time-consuming and costly tasks. There are many different sources of geographic spatial data and many ways to collect them. In practice, there are two main methods of data collection: (1) direct (direct data collection on the object e.g. LIDAR or its raw image); (2) indirect (based on data available in processed form (e.g. cadaster, maps, statistics, etc.) [Yanwen et al. 2017]. In both cases, a high degree of coherence is required for the application of specific data - that are associated with the different objects image- into an effective model [Madrazo 2019]. This also could involve creating scenarios for future urban growth. The number of cities in the world that have their own maps model (3D/2D) is constantly growing. Cities like New York, London, Amsterdam, Helsinki have created their own 3D model based on open CityGML data. This type of service can be used to access geographic information or datasets of several departments, moving from many basic maps to other information on energy

[8] The PTEee promotes the Spanish Priority Technology Initiatives (Iniciativas Tecnológicas Prioritarias -ITPs) among which one of the goal for 2020 is to encourage R+D+i collaborations between the public, scientific and business sectors on energy efficiency with a specific focus on PEDs. https://static.pte-ee.org/media/files/documentacion/itp-01-2019-distritos-de-energia-positiva-peds-tZU.pdf

[10] Among others, the Building Energy Software Tools. (www.buildingenergysoftwaretools.com)

and water consumption or may include the calculation of the solar potential of all roof and building surfaces. The data content in these city information model can be enriched without limit, and geometrical information are very useful, even more in the cases of a large number of buildings, enabling to calculate slope, aspect or roof surface, and to support a large number of analysis (e.g. solar radiation analysis and the design of Renewable energy sources (RES) and photovoltaic (PV) energy production in that case of self-consumption and energy communities)[11].

The need for innovative financing schemes

The Energy Efficiency Financial Institutions Group reported in 2015 [EEFIG, 2017] that investments of the order of €60-100 billion are required to improve the energy performance of buildings in Europe, while the International Energy Agency (IEA) in its 2°C (450ppm) scenario estimates a requirement of US$1.3 trillion in the period 2014-2035 globally [BPIE 2019]. These financial needs mean that they cannot be met by public funds alone and that also public–private partnership (PPP) must promote the energy performance improvement of buildings. The market has fully recognises that this is a low-risk activity, and that the lack of credible information on results prevents, in most cases, investments in retrofitting. [OptEEmAL 2019].

Adequate financial instruments to overcome market failures and sustain higher renovation rates are highly promoted by the EC[12] and ongoing studies[13] are seeking to validate three main assumptions: (1) improving energy performance has a positive impact on property value, thereby reducing a bank's asset risk; (2) borrowers have a lower probability of default as a result of more disposable income due to lower energy bills, with positive effect on bank's credit risk [source:EeMAP]; (3) implementing sustainable urban models provides notable health impacts on inhabitants, reduce harmful environmental exposures and mitigate effects of climate change, thereby improving economic savings for the healthcare system [Ortiz et al. 2019, Muller et al. 2019]. The availability of a large-scale pipeline of bankable projects to feed investment platforms and financial instruments is the key to upscaling and replicating successful projects, thereby reducing overall renovation process costs. It has been largely demonstrated [Salom et al., 2018] that the scale economy would ease the achievement of the building renovation ratios goals, by lowering the unitary required investments and optimizing the operative processes, from the technical to the administrative one's. Furthermore, this approach is wired by most recent initiatives and regulations (e.g. RD244/2019) that encourage the private sector relationships from an energy and business point of view, by introducing new concepts and legal frames as the so-called energy communities. Due to the complexity and the large number of administrative issues to be solved in such processes, the implementation of new financial schemes and partnerships with local actors (e.g. SMEs, financial institutions, energy agencies or private investors) is crucial for success [Salom et al., 2018]. Cities and regions in cooperation with local financing institutions and investors help to overcome these shortcomings by developing financial products, financial model

[11] Among others, the commercial suite of the software Aurora includes design and financial analysis tools custom built for C&I projects.

[12] The STUNNING (SusTainable bUsiNess models for the deep reNovation of bulldiNGs) Renovation Hub is a web-based knowledge sharing platform addressing technology and business models for building renovation whose aim is benchmarking innovative and adaptable refurbishment packages and sharing and promoting successful business models for their large scale deployment and replication.

[13] On this matter, the MED Efficient Buildings Community, established by interreg MEDNICE Project, gives an overview of available existing barriers and financing schemes to implement Energy Efficiency projects in Public Buildings. (https://efficient-buildings.interreg-med.eu). Other relevant initiatives funded via the EC' Horizon 2020 Programme are the Energy efficient Mortgages Action Plan (EeMAP) that aims to create a standardised "energy efficient mortgage", according to which building owners are incentivised to improve the energy efficiency of their buildings or acquire an already energy efficient property by way of preferential financing conditions linked to the mortgage, or the Energy efficiency Data Protocol and Portal (EeDaPP) project to design and deliver a market-led-protocol to enable the recording of data relating to energy efficient mortgage assets and which will be made accessible via the design of a common data portal.

(e.g. PPP or cornerstone management model) and innovative methods (e.g. one-stop shops) combining affordable financing with people-centric technical assistance (e.g. EuroPACE Platform). The above mentioned solutions make investment in energy efficiency and active measures more attractive and easier for different types of homeowners (e.g. medium income households) and for specific types of buildings (e.g. condominiums) [BPIE, 2019].

2. METHODOLOGY

The following key aspects will briefly describe the potential and main features of the PEDRERA model approach whose aim is to widely support and implement the large-scale renovation projects towards sustainable districts by:

• Defining of fields (issues) and indicators that allow to evaluate, guide and support the best retrofitting strategy, according an holistic outlook from multiple domains and sources;

• Integrating and aggregating of data at building and district scale in order to assess the potential for renovation according specific areas of interest (categories) and scopes.

• Ranking and prioritizing values in an integrated and multidimensional model framework which facilitates - according different stakeholders' profiles - to explore potential cluster of buildings to be renovated, propose rehabilitation measures and refurbishing scenarios, and evaluate the economies of scale.

• Designing a reliable business model able to validate the whole renovation process, and to build trust in the business opportunity for investors and users.

According a wide PEDRERA vision beyond a reliable business tool, the model - still in processing - is meant to offer additional services, empowered by its implementation into a platform environment enabling: (1) to explore urban areas and automatically evaluate their renovation potential based on specific indicators; (2) to create and assess retrofitting plans supported a the reliable business plan; (3) to follow up the impact and the co-benefits of the energy renovation. Indeed, the model refers to a wider "district performance" concept, based on an holistic approach of a few indicators that really can strengthen both the stakeholders recruitment, the design and the fulfillment of the results attended. Thus, many input and indicators considered in the model may appear far from the energy efficiency goals of the renovation process itself, but the reason is stated in the remark of both the real interests of the stakeholders when financing and tackling the process, and the scope of the process.

3. PEDRERA MODEL

Building renovation programmes need to adopt a broader approach to increase awareness and emphasize the co-benefits of the renovation plans such as the appreciation in housing value, increase of building lifespan and improved health benefits for both the household occupants and the healthcare system. Aligned with this vision, the business model is powered by the integration of processed input that can be assumed to assess more than one indicator. Input data are supposed to be automatically retrieved from a large number of external data sources (e.g. weather, demographic/aging condition, income/energy poverty or socio-economic rating, energy demand and consume data, etc.) while other input are measured, calculated or simulated. Each indicator is arranged in specific issue and category, and its value and prioritization rank will modify the business model result [Civiero, 2017].

The model is designed according to a step by step approach where a different deepening of input - output data belongs to each phase of the renovation process (Figure 1). Seven main phases are identified where different activities and action are required: (0) the

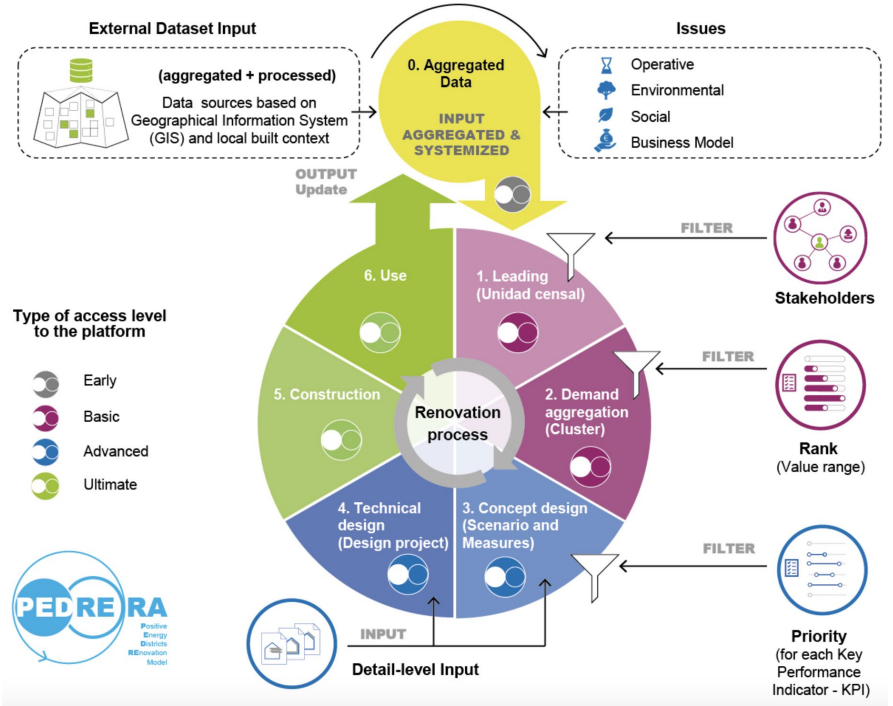

Figure 1. Renovation process: phases and interactivity of the model with data. Source: authors.

"data aggregated" - early aggregation of information, (1) the "leading"– boundaries definition of the energy community at district level (e.g. unidad censal), (2) the "demand aggregation" – clustering, (3) the "concept design" – measures to adopt according a package of solutions, strategies and potential scenario, (4) the "technical design" – economic evaluation (PEC) and business model validation, (5) the "construction phase", (6) "use".

Each phase provides a deeper and different type of information elaborated in the model. The early aggregation of input data in four main fields of performance of the district (Operative, Social, Environmental, Business Model) represents the baseline of the renovation process. In the "leading phase" an evaluation tool of the model manages all input, and returns the "district performance" dataset meant for each issue. Learnt lesson from past experience and literature review, demonstrates that in the first stage of the renovation process, investors need just a very clear and simple information able to show them the potentialities and risks of an investment. Thus, a few number of indicators are strictly linked with the definition of a weighting scheme, namely applying some values that represent the importance a certain indicator has over others.

Once input are collected, systemized and filtered, the first phase is overtaken, and a second level of information is required to

Issues	Categories	Indicators	Access	Scope
Business model	Economic	Grant, and EE revolving funds size	A	Financial Appraisal/Renovation Measures
		PEC (including Economies of scale)	A	Financial Appraisal/Renovation Measures
		Public Subsidies for low income	A	Financial Appraisal/Renovation Measures
	Financial management	Annualized Return on Investment (ROI)	A	Financial Appraisal
		Cash Fow (according works schedule/phase)	A	Financial Appraisal/Renovation Measures
		End user type of loan (50/50, 60, 120, …)	A	Financial Appraisal
		Housing implementation price value	U	Financial Appraisal/Marketing
		Housing prices (value/sqm)	A	Financial Appraisal
		Loan Rate (Monthly payments max value/dwelling)	A	Financial Appraisal
		Loan Years	A	Financial Appraisal
		New job opportunities	U	Financial Appraisal/Welfare & Security/Marketing
		Operational costs (each stakeholder)	A	Financial Appraisal/Renovation Measures
		Property (public/private ownership)	E	Financial Appraisal/Renovation Measures/Energy model
		Property ratio (Owners/tenants)	A	Financial Appraisal
		VAT (each activity/stakeholder)	A	Financial Appraisal
Environmental	Energy community	Energy flexibility (between buildings) (Prosumer index)	U	Energy model/RES production/Marketing
		Montly/annual energy bill reduction	U	Financial Appraisal/Marketing
		Number of buildings affected	B	Financial Appraisal/RES production
		Number of dwellings affected	B	Financial Appraisal
		Self-consumption Energy community (ScEC) reference	B	Financial Appraisal/RES production
		Radius Max distance (<500 m) inside the same ScEC	B	Financial Appraisal/RES production
		Solar irradiance (horizontal surface)	B	Renovation Measures/Energy model/RES production
		Solar irradiance (vertical surfaces)	B	Renovation Measures/Energy model/RES production
	Energy consumption	Electric consumes (after works)	U	Financial Appraisal/Marketing
		Electric consumes reduction (%)	U	Financial Appraisal/Marketing
		EPC (comparison before and after r.w.)	U	Environmental impact/Marketing
		EPC implementation (upgrade)	U	Environmental impact/Marketing
	Environmental potential	Electric consumes (before renovation works)	E	Renovation Measures/Energy model
		EPC (before renovation works)	E	Renovation Measures/Energy model
		GhG emissions reduction (%)	U	Environmental impact/Marketing
		Primary energy consumption reduction (%)	U	Environmental impact/Marketing
Operative	Building Function	Property type ratio (residential/other)	A	Financial Appraisal/Energy model/RES production
	Building Size	Floors (other function) sqms	B	Renovation Measures/Energy model
		Floors (Residential) sqms	B	Renovation Measures/Energy model
		Number of levels (ground + floors)	B	Renovation Measures/Energy model
	Building Technics	Building cluster type according Age	B	Renovation Measures/Energy model
		Building cluster type according Technologies	B	Renovation Measures/Energy model
	Operational potential	Envelope extension	E	Renovation Measures/Energy model
		Roof extension (general + accurate)	E	Renovation Measures/RES production
	Renovation Strategy	Renovation Measuress (Package of measures)	B	Financial Appraisal/Energy model
		Renovation Strategy (permanence in the place)	B	Renovation Measures
		Renovation target no.A (Deep Renovation)	A	Financial Appraisal/Renovation Measures/Energy model
		Renovation target no.B (Accessibility)	A	Financial Appraisal/Renovation Measures/Welfare & Security
		Renovation target no.C (RES individual/community)	A	Financial Appraisal/Renovation Measures/RES production
		Renovation works scheduling (duration of works)	A	Financial Appraisal/Renovation Measures
	Vulnerability potential	Accessibility (guarantee: yes/no)	E	Renovation Measures/Welfare & Security
		ITE (certificate: yes/no)	E	Renovation Measures/Welfare & Security
Social	Risk solvency	% of population in age range	E	Financial Appraisal/Energy model/Welfare & Security
		Gross disposable households incomes	E	Financial Appraisal/Renovation Measures/Energy model
		Households composition (no. of adults/children)	B	Financial Appraisal/Energy model
		Life expectancy (ref. to health/age/pollution)	E	Financial Appraisal/Energy model/Welfare & Security
		People at risk of energy poverty (income decile)	B	Financial Appraisal/Renovation Measures
		Unemployment	A	Financial Appraisal/Energy model

Figure 2. Input and output that will be implemented in the PEDRERA model and managed by the multi-step form wizard of the platform. Source: authors.

guide the design and find out the strategy that best fits with the goal. In the second phase, the boundaries and the preferences of the stakeholders involved in the retrofitting project will be applied through pairwise comparison of indicators. The model provides as outcome the calculation of composite performance indexes (categories), as well as the information on compliance with the targets and boundaries established by the user.
In the third phase a cost-benefit customized function will evaluate retrofitting alternatives, taking into account both (a) the available data and information, (b) the database of renovation measure and (c) the system of filters and prioritization applied by the user on the indicators.

Additional more detailed input can be introduced into the model to better perform the Concept and the Technical design in the third and fourth phases. This information will help to refine the knowledge about the building and user' profile, as well as the loans strategy, the costs and the renovation works/cash flow schedule. After the Construction phase is concluded, during the sixth phase of Use, updated information can be uploaded to the on-cloud database, where data can be used for monitoring activities/continuous evaluation (e.g. monitoring of the energy consumes or analysis of the building performance, which can be used for the promotion of new business/intervention actions).
The PEDRERA model is designed to run on web platform with different suited access levels (Early, Basic, Advanced, Ultimate). The PEDRERA model will be implemented into the operating URBANZEB platform provided by CICLICA, main partner of the research project (https://ciclica.eu/en/urbanzeb_en/). Authorized stakeholders will monitor and analyse the whole system sustainability status online. Once stated the priorities and performance required, the users launch a set of simulations by the wizard panel and the data inserted and processed will generate scenarios. In this way a great deal of subjectivity can be introduced to the process finding a relationship between the goals established by the user and relating them to the evaluation criteria (indicators) of the model. Otherwise, users can set up the goal and the algorithms will calculate the best business model scenarios required. The performance of each indicator (e.g. costs, revenue, ROI, regulation compliance, etc.) is the result of distinct algorithms running in the model where the information - mandatory and optional - will be automatically collected and calculated according specific scopes (Figure 2).

CONCLUSION

Research and development in energy transitions should necessarily face both technological and socio-economic problems. Viable business cases remain the weakness point of many renovation plans, while novel methods to integrate co-benefits of smart city solutions in business models are still in their early stages. Therefore, in a sustainable long term vision, the goal of this innovative model is to promote solutions able to create the trust and commitment from civil society to embrace and foster the overall development of the smart cities to come as a whole.
The data which is necessary to calculate sustainability indicators in building renovation areas are distributed in multiple sources, each one managed by a different organization, even from apparently far domains, and of different types. Additionally, one of the main challenge of the future is not only the data availability - which still represents a gap in some European urban areas - but how to integrate heterogeneous data in order to get a comprehensive understanding of district scale renovation complexity thus

enabling better decision support and impact assessment. In spite of a large amount of data about cities are increasingly available and processed according multiple domains and formats , nonetheless there is still a lack of tools/services oriented to the relevant key stakeholders of the building retrofitting processes: building developers, financial institutions, public administrations, building owners and tenants. In order to take informed decisions in their respective realms, these stakeholders need to have access to information which suits their knowledge and capacities. Furthermore, the possibilities of using city model maps are inherently unlimited and can be addressed to current and future city issues that may arise.

The technological-economical feasibility assessment, the proper identification of the types of intervention and their combination in potential scenarios must be investigated and estimated at a multi-buildings large scale, with an effective and interdisciplinary design approach integrating in a whole system the socio-technical aspects into the feasibility study of economical, social, environmental and technical issues. Conventional energy planning and technological learning models are not sufficient because of their inability to deal with issues such as the behaviour of consumers, prosumers of energy or self-consumption community and investors. The role of models in the energy field is cross-sectorial and the use of common principles and techniques are stimulating a rapid development of multi-disciplinary researches (e.g. multi-domain models, GIS cities modeling, open data, etc.), which is an essential part of innovation.

ACKNOWLEDGEMENTS

The research project was funded by EU Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement No 712949 (TECNIOspring PLUS) and by the Agency for Business Competitiveness of the Government of Catalonia, ACCIÓ.

PAPER #4.06

PURPOSEFUL PLAY: BRIDGING THE ENERGY-EFFICIENCY GAP IN CITIES

Malini Srivastava[a]
[a] University of Minnesota, Minneapolis, MN, USA

ABSTRACT

In the United States, buildings use almost 40% of energy produced and are responsible for 38% of greenhouse gas emissions. Urban areas account for a majority of global energy use and carbon emissions. Compared to usual current practices, energy-efficiency focused urbanization has the potential to reduce energy use by more than 25%. Energy-efficiency measures thus provide an opportunity for substantively impacting global carbon emissions from and energy use at the City scale. While energy efficiency is the cheapest method to reduce energy use, owners and occupants often fail to adopt energy-efficiency measures, a phenomenon known as the energy efficiency gap.
The work described here shows that serious pervasive energy games (SPEGs) have the potential to simultaneously engage individual community members' particular needs while informing city-scale interventions that could impact climate change at larger scales. This approach was tested in our team's winning entry to the nationwide Georgetown University Energy Prize (GUEP) competition, opened in 2014 to American cities with populations between 5,000 and 250,000 people. Over a period of two years, our team effort successfully reduced citywide municipal and residential energy use by 6.85%, normalized for population growth, weather effects and energy source, by the competition organizers. Through iterative research, design and implementation of serious pervasive energy games (SPEGs), we connected the city's built environment and its energy use to the community occupants.
This paper discusses one of the game designs that included individual action, neighborhood cooperative action, nested public-municipal interaction and other engagement activities that empowered community members to make city-wide impacts through personal action by forming active communities in the efargo game.

KEYWORDS

Serious energy games; pervasive games; energy efficiency gap; nested scales; energy efficiency; energy savings.

INTRODUCTION

Long-term temperature observations are consistent and widespread evidence of a warming planet (United States Global Change Research Program, 2018). With high confidence, the likely range of the human contribution to the global mean temperature increase over the period 1951-2010 is 1.1o F to 1.4o F. As of 2018, an estimated 55% of the world's population lives in urban areas, a proportion expected to increase to 68% by 2050 (United Nations 2018). Seto et al (2014) project that urban areas are responsible for 67%-76% of global energy use and 75% of carbon emissions. In the United States, buildings consume almost 40% of all energy produced (U. S. Energy Information Administration 2019 (2)), over 70% of all electricity produced ("Buildings Share of U. S. Electricity Consumption (Percent)" 2012), and are responsible for producing 40% of CO 2 emissions ("Carbon dioxide emissions for

U. S. buildings, by year" 2012). As such urban built environments lend themselves as a location for large-scale interventions.

Despite the fact that energy-saving measures have cost-saving potential, several studies identify barriers preventing owners and occupants from pursuing them. Hirst and Brown (1990), in coining the term "energy efficiency gap," note the failure of households, businesses, manufacturers and government agencies to take full advantage of cost-effective energy-conserving opportunities. Moreover, occupant behavior can have a significant impact on the energy use and causes uncertainty in the predictions of building energy use even for the same properties in similar climate conditions. Hong and Lin (2013) report that austere workstyles in offices consume up to 50% less energy while wasteful workstyles consume up to 90% more energy compared to standard workstyle. There is growing evidence that,

> "behavioral anomalies may influence investment decisions, and such anomalies, ranging from self-control problems to reference dependent preferences to biased beliefs and inattention, are becoming a commonly cited explanation for the energy efficiency gap (Gillingham and Palmer 2013, 33)."

Different issues are relevant to different consumer groups making one-size-fits-all efforts effective only to a limited audience and less effective to other audiences. Heterogeneity presents researchers with both an opportunity and a challenge (Gillingham and Palmer 2013) in energy efficiency programs.

This research contends that Serious Pervasive Energy Games (SPEGs) may successfully address the heterogeneous needs of the community, by accommodating the diverse realities, goals, needs and modes of play of various community members. This paper discusses the design, implementation and results of a SPEG called efargo game in the City of Fargo, North Dakota. The efargo game was released publicly and open to voluntary participation in order to study the potential of incentivizing owners and building occupants through games, to make changes in energy use behavior, leading to energy savings.

1. SERIOUS GAMES WITH ENERGY GOALS

Serious Game research is an established and expanding field. Serious Games are fun, but they have goals beyond entertainment. Serious Energy Games (SEGs) focus on energy as their primary subject matter. This research has identified 127 Serious Energy Games created worldwide since the 1970s, both reflecting and reacting to contemporary energy issues. Based on this research,

1.1 Serious Pervasive Energy Games

Pervasive Games create social, temporal and spatial expansions of game life into ordinary life (Montola, Stenros, and Waern 2009). According to Gustafsson, Bang, and Svahn (2009) traditional learning games may have difficulty achieving a transfer of actions between game play and actual life but pervasive games can include reality in the game play, creating an opportunity for "a situated learning experience." Transferring learning from within a game's "magic circle" to the real world is a challenge (Gustafsson, Katseff, and Bang 2009), but Pervasive Games, by expanding the magic circle into ordinary life's social, temporal, and spatial constructs may enable transfer to occur simultaneously. Serious Pervasive Energy games (SPEGs) are games aimed at impacting energy use outcomes by incorporating actual life energy use, energy users, and energy use infrastructures and structures within the game. The documented history of

SPEGs begins in 2007 with the Power Agent game, implemented by Anton Gustafsson and Magnus Bang, designed to encourage Swedish teenagers and their families to reduce energy consumption. Of the 127 SEGs, there are a total of 14 SPEGs of which 11 have reported results. The 11 that have reported results have achieved substantive results in short periods of time. Energy savings range from 8%-38% of those games reporting energy results. Behavior tests report changed habits, improved attitudes, involvement in energy savings and people formulating new energy saving strategies. Of the SPEGs reporting results, only 3 have been designed and implemented in the United States in small targeted implementations and only 2 have reported results (Energy Chickens (Orland et al. 2014); Dropoly; and Makahiki). In the Energy Chickens game 69% of game participants indicated that the game helped them be more energy conscious and participants reduced their plug load by 13% from baseline (table 2.6). 95% of the participants rated the Makahiki game as educational.

1.2. The Georgetown Prize

The opportunity to further design, implement and test SPEGs as a way of bridging the energy efficiency gap presented itself in the nationwide competition conducted by Georgetown University called the Georgetown University Energy Prize (GUEP). The GUEP goal was to reduce the energy use of cities with populations ranging from 5,000-250,000 people. The competition duration of the semi-finals was January 2015 to December 2016. Normalized data collection of energy use in 2015 and 2016 was compared against a baseline energy use during years 2013 and 2014. In the energy use data collected and published by the GUEP, efargo's work resulted in Fargo being ranked as the fourth highest energy saver and overall winner of the Georgetown Prize. Long (1958), based on a year of field study in the Boston metro area, proposes that "the local community can be usefully conceptualized as an ecology of games." He noted that games provide goals to gamers, sense of structure, the sense of being on a team, and determine roles and strategies and tactics to achieve those goals. Imagining the locality of Fargo as an ecology of games with several interconnected games and gamers as actors of note, a partnership called efargo (led by this author) was established between North Dakota State University, the City of Fargo, ND, and local utilities in 2014. The University (through the efargo research group) provided design, scholarship, research, production and implementation. The utilities provided information and connection to their customer bases. The City provided permissions, resources and connected the team to various for-profit and nonprofit organizations and governmental agencies such as schools, parks, fire stations etc.

1.3. Game locations and types

While this paper primarily focuses on the scaled structures and narratives within the efargo game, there were other games designed, implemented and tested in the community. The first SPEG titled, efargo game, targeted residential energy use, rental and ownership. This game was launched in late February 2016, and ended with a community Earth Day celebration in April 2016. Another SPEG called K-12 Energy Challenge targeted the municipal sector of the Georgetown University Energy Prize, was focused on reducing energy use in K-12 schools while also educating students about energy waste, energy use reduction and energy efficiency (Srivastava 2019). Lastly, several energy games were designed and played at community events where the efargo research team was invited to provide outreach related to energy education and awareness. The community space included the local

farmers market, street fair, winter festival, local shopping malls, downtown community partnership etc. The games at these events included the light bulb game (Figure 1), the energy wheel of fortune, the weights game, the earth piano and others.

Figure 1. Community Games. Source: (efargo, Troy Raisanen, Greta Berens, Dylan Neururer, Alex Jansen, Sam Goodman, Author 2020)shared photographs.

1.4. The scaled narratives within the efargo game

For the efargo game, gamers had to complete energy-saving actions primarily in their homes in order to earn game points. Within the game website, each token (blue circle or coin) indicating a theme such as lighting, heating, community action etc., had to be selected and then moved by a gamer to climb challenge levels represented by blocks. Each level (made up of seven blocks) was associated with a level of difficulty (Level 10-70). For each token, Level 10 (the first level) presented information and quizzes for the gamer to complete for which short tutorials were provided within the game.

> "Level 20 included an easy action item associated with that token that is typically a low-cost or no-cost energy-saving effort such as changing 5 light bulbs in the home from incandescent or fluorescent to LED. Level 30 asked people to share their participation in that week's token through social media or traditional media (phone, email, conversation),

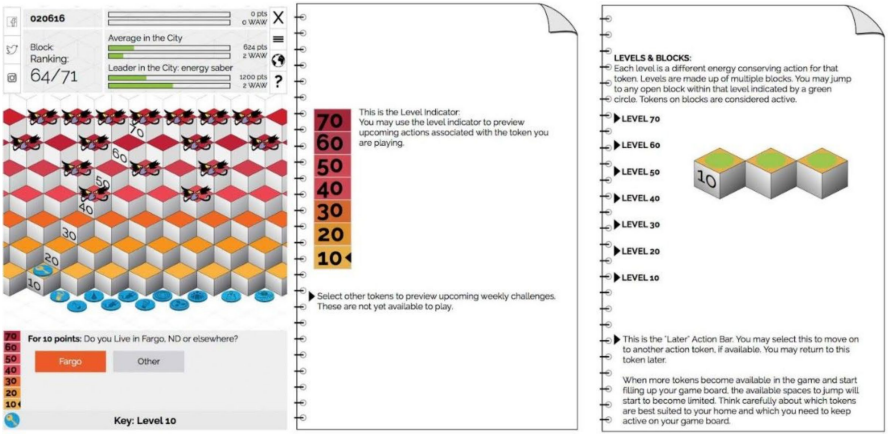

Figure 2. The efargo game board, dashboard, communications box, tokens, challenge block levels and mapping. Source: (efargo, Peter Atwood, Ian Schimke, Troy Raisanen, Nick Braaksma, Greta Berens, Author 2020)

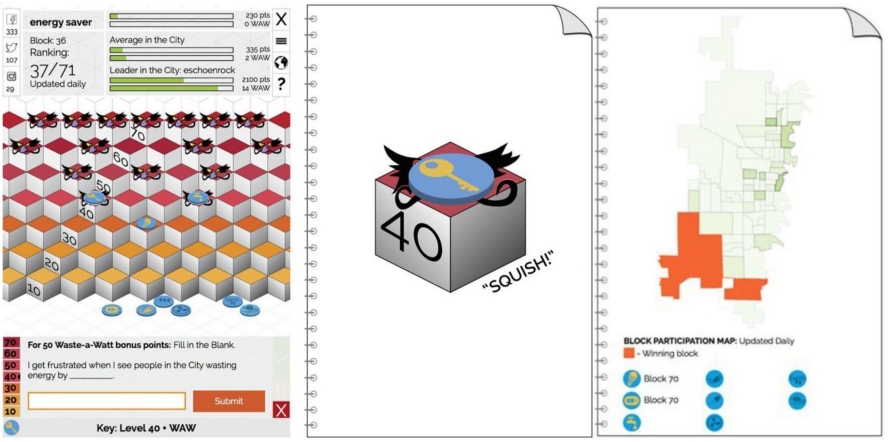

Figure 3. efargo game map based on census blocks. Source: (efargo, Peter Atwood, Ian Schimke, Troy Raisanen, Nick Braaksma, Greta Berens, Author 2020)

> inviting friends, family, and neighbors to participate. Levels 40-70 asked gamers to complete energy-conserving action items with increasing levels of difficulty, requiring more time, effort, cost or preparation (Srivastava 2016)."

As they played the game, information about energy waste and energy efficiency was provided to the gamers. Gamers implemented energy-saving actions in their homes and shared information through social and other media about their actions. Gamers earned points for their activities and could see their scores in comparison to other gamers in the dashboard (upper left corner) (Figure 2), how much they had advanced in the game, and the ranking of their block that allowed them to see how their block was faring in the game in comparison to other blocks in the city. The game board also included a map showing the performance of the city as a whole, based on census blocks (Figure 3). The game scores of all gamers in a census block were aggregated to create the block participation score. The census block with the highest block participation score for the week was declared the block winner. The game included a weekly reward (a $50 gift certificate) given to a randomly selected gamer, the weekly champion from the winning block (Figure 4). Since the game incentivized the aggregate block performance, activities that involved connecting with neighbors in order to achieve broader participation from the block were as important as achieving energy reductions in

Figure 4. efargo weekly winners and champions. Source: (efargo, Greta Berens, Ian Schimke, Author 2020) (Srivastava 2016)

Table 1: Sample of community responses to one of the Waste-a-Watt question (total 700 responses)

	I wish the City would _____ to save energy.	Municipality actions/ policies for the City infrastructure	Municipality incentives for the community
Renewables	Use more solar resources	x	
	Use more solar panels on city buildings	x	
	Put in solar panels	x	
	Implement more sustainable practices, like solar panels	x	
	Invest in renewable sources	x	
	Use nuclear power	x	
	Use sustainable energy sources (preferably wind--vertical tube designs don't take up much room--or solar)	x	
	Require a renewable portfolio		x
	Actively support tax credits for green or alternative energies or other sustainable energy initiatives.		x
	Utilize wind	x	
	Utilize wind energy	x	
	Do more solar power	x	
	Use more solar energy	x	

Table 1. Sample of community responses to one of the Waste-a-Watt question (total 700 responses)Goodman, Author 2020)shared photographs.

individual homes. Nested within the game were bonus points awarded for landing on and answering a "Waste-a-Watt question". The gamers had to land on specific locations in the game board indicated with a Waste-a-Watt icon (Figure 2). These icons were located in the higher levels of the game (Level 40-70). As a result, the fundamental actions on Levels 10-30 had to be completed to access the bonus points associated with questions accessed by clicking the Waste-a-Watt icon.

Gamers' responses to these questions were posted on the game website (Table 1 contains a small sample from 700 responses), creating a dialog within the gaming community. Gamers earned bonus points by responding to Waste-a-Watt questions, incentivizing community participation. Additionally, the last two tokens were focused on creating community-municipality dialogue and a celebratory community event, expanding the game beyond the home to a larger scale. The gamers were connected to an app called Sidewalk, commissioned by the city for city-community dialogue, through the efago game. In this app the gamers could ask questions pertaining to policies, incentives, goals, action items that they believed the city could be involved in or promote. For the community event, on Earth Day weekend in 2016, the efargo group organized a space in downtown Fargo. Several experts from organizations and corporations working on energy issues were invited to the event. Gamers could earn points in the game by learning about all the energy-related work that was happening in the community.

2. RESULTS OF GAMEPLAY

Energy-use data related to household energy use was collected before, during, and after the game. Of the 322 people who joined the efargo game, 55 people completed a pre- and post-game survey. Of these 55 people, 26 people gave permission to access the energy use data. Of these, 18 people were identified as customers with active accounts (13 with Xcel Energy and 5 with CCEC). 13 of the 18 gamers had complete electricity-use records covering the 2013- 2016 period (provided by the utilities)

Data for these thirteen gamers was analyzed using ETracker, a software application developed by Kelly Kissock at the University of Dayton (Ohio), with support from the United States EPA for the Energy Star Buildings Program. ETracker "uses ambient-temperature regression models to reduce the influence of changing weather so that retrofit savings can be more accurately measured" (Kissock 2003). Two study periods were considered for analysis: during game play and after game play. The first study period (during game play) was defined as March 2016 – April 2016. The second study period (after game play) was defined as May 2016 – December 2016. The ETracker prediction was made on the basis of utility bills collected for a four-year period (2013, 2014, 2015 and 2016).

Energy use prior to March 2016 was used to create energy-use data files for each of the individual gamers. Over each study period, each gamer's actual energy use (in kWh) was reported from utility records. Individual gamers' predicted energy use from ETracker was then compared to their actual energy use data from the utilities, and the difference was calculated for each gamer. During the first study period, some individual improvements in energy use were observed: of the 13 individual gamers, 7 showed energy-use reductions. A monthly total drop of 27 kWh, or 0.23%, and a marginal drop in mean difference between actual and predicted energy use (-2 kWh) were observed. Post-game analysis was conducted on the remaining months of energy use data available, from May 2016 to December 2016. A monthly total drop of 1,273 kWh, or 11.65%, and an appreciable drop in mean difference between actual and predicted energy use (-98 kWh) were observed. Figure 5 summarizes the individual gamers' energy use in the two study periods. An increased number of gamers experienced energy savings in the second study period. Thus, with respect to the comparison of (a) predicted energy use with (b) actual energy use, both before and during the efargo game, findings are positive and consistent with SPEG efargo game reducing energy use, but the findings are not statistically significant (p = 0.25 (>0.05), likely due to small sample size.

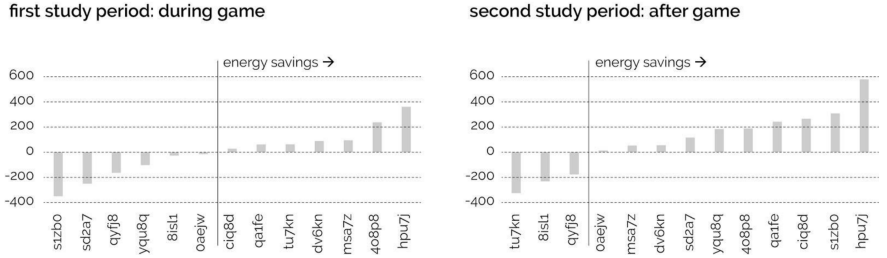

Figure 5. Individual gamers' energy use (Author, Peter Atwood, Mike Christenson).

While the Georgetown University Energy Prize established the core goal of reducing community-wide residential and municipal electricity and natural gas consumption, the structure left it up to each individual community how best to accomplish this goal. The final evaluation of the Prize accounted for energy-use reduction, but also considered whether innovative, sustainable, replicable, and scalable approaches were developed that had potential for wider application. Energy use data submitted by the cities was normalized by the GUEP team according to the protocols outlined in the GUEP
(Srivastava, Nelson 2017). The normalized data constituted the overall results for the City of Fargo for competition years 2015 and 2016 compared to baseline years 2013 and 2014. In two years, Fargo reduced overall energy consumption by over 172,361,882,500 BTUs. Estimated CO2e saved was 49,719 metric tons, and the overall energy consumption reduced on average per-household was over 8,165,800 BTUs. Although it cannot be conclusively stated that the playing of games led to the substantive energy use reductions shown in the GUEP results, it is nevertheless noteworthy that three of the ten cities with the greatest energy savings were gaming cities in addition to other activities (Figure 6). At the end of the competition, the winner (Fargo) and two of four honorable mentions (Fort Collins, CO and Walla Walla, WA) were gaming cities (Srivastava, Nelson 2017).

CONCLUSIONS & LIMITATIONS

In making the local community analogous to a game, Long (1958) contends that games are not trivial but quite the opposite. He contends that,

> "... (hu)man is a game-playing and a game-creating animal ... and that it is through games or activities analogous to game-playing that (s/)he achieves a satisfactory sense of significance and a meaningful role (Long 1958, 252)."

Long posited that politics, banking, contracting, journalism, civic organizations, and ecclesiastics as interconnected, albeit different, games sharing a common locality where each game has well-established goals, known and understood ways to behave and a set of strategies and tactics for gamers. In

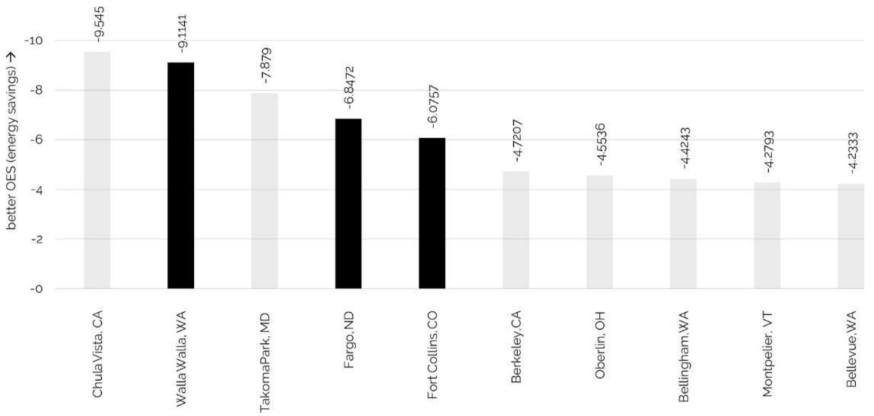

Figure 6. Individual gamers' energy use (Author, Peter Atwood, Mike Christenson).

the efargo game, the most meaningful social expansions not only increased the numbers of people involved but ensured that various constituencies (home owners, renters, community experts, businesses, municipal government, schools and other organizations) were involved, actively participating towards shared goals. This meant that while the game needed temporal flexibility, so people and entities could participate when they were able to, an overall synchronous structure was also needed for meaningful competitive play to occur and shared goals to be realized. Thus the game design had to balance flexible play and a synchronous structure with a defined play duration. Structures game elements such as the Waste-a-Watt questions revealed that frequent opportunities to create a meaningful sense of community within the game elicited the greatest dialogue from gamers (700 responses). Other dialogue structures between the gamers and designers (Key tokens), between gamers and the City (City Token, Sidewalk app) and between multiple organizations, corporations and the gamers (Community Token, Earth Day event) also garnered considerable responses. While dialogue and data collection within the game structure were successful in getting gamer responses, the final attempts to collect post-game surveys and energy use data collection after the gameplay period, were not as successful and had a much smaller response rate. Lack of gamer engagement in the post-game traditional survey format, severe database limitations on the Utility end, such as needing exact format and spelling duplication of gamer addresses made it difficult to locate the gamer utility invoices even for those gamers who had signed the release to access their data. Embedding surveys and energy use data collection within the game, where gamers are asked to submit their own energy use invoices rather than trying to acquire them from the Utility after the game play, needs to be tested in the future.

ACKNOWLEDGEMENTS

The work included in this paper would not have been possible without several members of the efargo team including but not limited to Peter Atwood, Troy Raisanen, Mike Christenson, Nate Wallestad, Ian Schimke, Greta Berens and Nick Braaksma. This research was funded by grants from the City of Fargo and the North Dakota Department of Commerce.

PAPER #4.07

OPTIMAL OPERATION STRATEGIES OF THREE DIFFERENT HVAC SYSTEMS INSTALLED IN A BUILDING

Yeo Beom Yoon[a], Byeongmo Seo[a], Suwon Song[b], Soolyeon Cho[a]
[a]North Carolina State University, NC, USA
[b]Korea Institute of Civil Engineering and Building Technology, Ilsan, Republic of Korea

ABSTRACT

A public service building in Korea is undergoing a retrofit process, adding heat pump systems, especially variable refrigerant flow (VRF) systems. The building currently has both central and zonal HVAC systems installed. Absorption chillers provide chilled water to both air handling units and fan coil units. Some rooms also have air source VRF heat pump (HP) systems installed, which have been added after the construction to provide additional energy. Unfortunately, these HVAC systems still do not meet the heating and cooling loads of the building. Simulation modeling processes were conducted to identify the building's thermal performance, verify the peak heating and cooling loads, and propose optimal additional VRF-HP systems to be installed. Optimal operation strategies were proposed for three different HVAC systems (i.e., AHUs, FCUs, and VRF-HPs) after adding additional VRF-HP systems to the building. Results show that operating the VRF-HP system as a main system, while central HVAC system as a secondary system, can reduce the building energy consumption. It is also required a low capacity of the additional VRF-HP system.

KEYWORDS

Air handling unit; VRF system; fan coil unit; system operation; energyPlus.

INTRODUCTION

Some existing buildings do not meet heating and cooling loads. This happens due to usage changes in spaces and addition of new equipment over time. Global warming is also a likely contributor to the additional cooling demand. These factors increase or decrease internal heat gains for which more heating and cooling energy is required. To overcome this issue, studies have been conducted on the retrofitting of buildings.

Luddeni et al. (2018) conducted research to reduce the building energy consumption of an office building in Italy by improving insulation performance, replacing windows, using high-efficiency equipment, and improving boiler efficiency. Somasundaram et al. (2020) applied low-emissivity windows to reduce the building energy consumption, while Biswas et al. (2019) conducted research to reduce building energy consumption by enhancing insulation performance. Previous studies have mostly applied energy efficiency measures or strengthened thermal insulation to reduce building energy consumption. Some studies attempted to reduce the energy consumption of buildings where heating, ventilation, and air-conditioning (HVAC) systems with sufficient capacity are already installed.

The target building of this study is a public service building where the capacity of the HVAC system installed is insufficient. An additional stand-alone air conditioner and a variable refrigerant flow heat pump (VRF-HP) system were installed to the target building to overcome indoor thermal discomfort, yet

doing so did not solve the problem of thermal comfort.
The purpose of this study, therefore, is to identify the capacity of additional HVAC systems and to propose HVAC system operation strategies, including the existing central HVAC system and fan coil unit (FCU) to improve indoor thermal comfort and reduce the building's energy consumption.

1. SIMULATING MODELING

1.1. Simulation software

This study used the EnergyPlus program version 9.0 developed by the U.S. Department of Energy (U.S.DOE). The OpenStudio program was used to implement the simulation model. The OpenStudio program is based on the EnergyPlus Engine and is one of the plug-ins of the SketchUp program.
EnergyPlus combines the advantages of the building loads and system thermodynamics (BLAST) in the building load analysis part and the merits of the DOE-2 program, which has the strength of a system-level analysis. In addition, EnergyPlus uses the heat balance calculation, which is recommended by the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE). It has the advantage of dynamic analysis, such as conduction, convective, and radiative heat transfer [U.S.DOE, 2018a].

1.2. Simulation model

The target building of this study is a public service building located in Ilsan, Republic of Korea. It is a six-story building with one basement floor and consists of multi-functional spaces, including office spaces, seminar rooms, and public service centers.
As previously mentioned, the actual target building does not have enough HVAC systems installed to meet the heating and cooling loads. The indoor air temperature could not meet the heating or cooling setpoint temperature due to the insufficient capacity of the HVAC system. Due to this problem, even in one space, temperature may vary, depending on the location.
To solve this issue, additional HVAC systems were installed in the target building, but these still do not have enough capacity. This study, therefore, aims to identify the additional capacity of the HVAC system that building needs through simulation analysis and to suggest the optimal operation strategies of the HVAC system to ensure energy consumption efficiency.
Figure 1 presents the simulation modeling of the target building. The simulation model is implemented based on the actual building drawings. The window-to-wall ratio of the target building is 35.57% on the east side, 22.17% on the west side, 37.19% on the south side, and 27.48% on the north side.

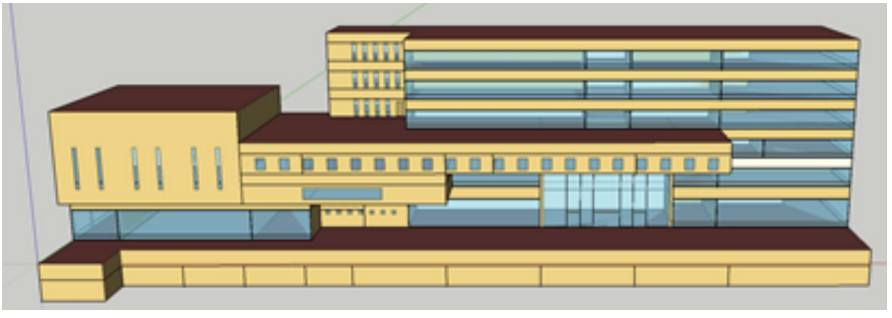

Figure 1. Simulation modeling

Tables 1 and 2 outline the properties of the building materials and the construction sets of the simulation model. The construction set is based on the drawings of the target building. The drawings of the target building do not have information about the building material properties, so we used the actual properties of the building materials that the EnergyPlus simulation program provided [U.S.DOE, 2018b].

The thickness of the air inside the interior wall and floor is not shown in Table 2. The EnergyPlus simulation program requires only thermal resistance values for air, which is one of the building materials. This is why there is no value for air thickness. The thermal resistance of the air layer is 0.15 m2·K/W for the interior wall and 0.18 m2·K/W for the ceiling. The U-value of windows is 3.35 W/m2·K, with the solar heat gain coefficient (SHGC) of 0.36 and visible transmittance (VT) of 0.27.

Table 3 presents the internal heat gain and infiltration values. Lighting power density is based on the drawing of the target building. Other values, equipment, and people are based on the DOE reference building (1980-2004) because the drawing does not include these values. The infiltration values are based on the infiltration modeling guidelines published by the Pacific Northwest National Laboratory [PNNL, 2009].

The heating and cooling setpoint temperatures in the simulation model are the actual setpoint temperatures used by the target building. The heating setpoint temperature is 20°C, and the cooling setpoint temperature is 26°C.

Material	Conductivity (W/m·K)	Density (kg/m^3)	Specific heat (J/kg·K)
Stucco	0.692	1,858	837
Concrete	0.530	1,280	840
Gypsum board	0.160	785	830
Roof membrane	0.160	1,121	1,460
Insulation	0.049	265	837
Metal Decking	45	7,480	418
Acoustic tile	0.060	368	590

Table 1: Building material properties

Construction	Outer layer to inner layer (thickness; mm)			
Exterior wall	Stucco (25)	Concrete (300)	Insulation (50)	Gypsum board (12)
Interior wall	Gypsum board (19)	Air	Gypsum board (19)	
Roof	Roof membrane (9.5)	Insulation (135)	Metal decking (1.5)

Table 2: Construction set

	Values
Lighting	13.83 W/m^2
Equipment	23W/m^2
People	0.054 people/m^2
Infiltration	Perimeter: 0.3 Air change per hour and Core 0.15 Air change per hour

Table 3. Internal heat gain and infiltration

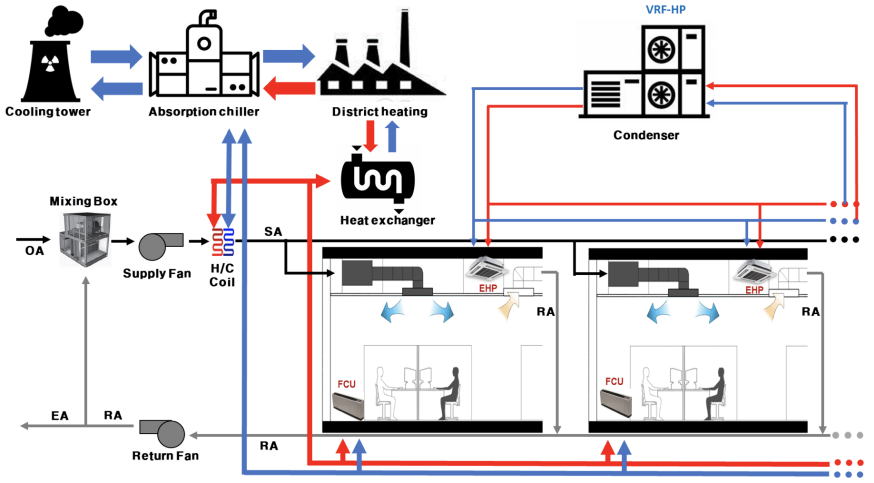

Figure 2. Diagram of the HVAC system in the target building

Figure 2 displays the conceptual diagram of the HVAC system installed in the target building. The FCU systems are installed in the perimeter zones, while the central HVAC systems are installed in the core zones. The existing HVAC system does not have a VRF-HP system in the upper right side of Figure 2 and is currently installing an additional VRF-HP system to improve indoor thermal comfort.

Information on the FCU system in the simulation model is the same as that of the FCU system installed in the target building.

For the absorption chiller and cooling tower, only the number is known, so the actual number of installations is entered, and the rest of the information is autocalculated by the simulation program.

1.3. Calibration

The simulation model was calibrated with the actual monthly electrical energy consumption. The cooling period is from June to September, while the heating period covers December, January, and February.

To calibrate the simulation model, we used the coefficient of variation of the root mean square error (CV(RMSE)) and Normalized Mean Bias Error (NMBE). ASHRAE Guideline 14-2014 provides the tolerance ranges of the calibrated simulation models, and the ranges differ, depending on the data frequency. The hourly data is 30%, whereas monthly data is 15% for CV(RMSE). For NMBE, hourly data is ±10% and monthly data is ±5% [ASHRAE, 2014]. The CV(RMSE) value is 14.4% which is in the tolerance range of the calibration model and NMBE value is 7.1% which is out of the tolerance range. NMBE value is for data value, and CV(RMSE) is for data pattern. Actual data are not enough to compare with simulation results currently. In the future, the simulation model will be updated with more detailed actual building data. Figure 3 compares the actual monthly electric energy consumption and the simulation results.

Equations for CV(RMSE) and NMBE are as follows:

$$RMSE_{period} = \frac{\sqrt{\sum (S-M)^2_{interval}}}{N_{interval}} \quad 1)$$

$$A_{period} = \frac{\sum_{period} M_{interval}}{N_{interval}} \quad 2)$$

$$Cv(RMSE_{period})(\%) = \frac{RMSE_{period}}{A_{period}} \times 100 \quad 3)$$

$$NMBE(\%) = \frac{\sum (S-M)_{interval}}{\sum M_{interval}} \times 100 \quad 4)$$

where,
y= monthly (or hourly) data
N= number of data
S= Simulation results
M= Measured data
Ninterval=number of data
Aperiod=Average of data

2. RESULT AND ANALYSIS

2.1. Analysis of the indoor temperature

Figure 4 shows the indoor air temperature patterns for the winter and the summer representative days. The winter representative day is February 6, while the summer representative day is August 4—both reflect the typical outdoor air temperature pattern in the winter and the summer seasons.
Since the temperature patterns of all rooms in the building cannot be expressed, we selected the office space on the fifth floor. The core shown in Figure 4 is the core of the office space, while perimeter refers to the perimeter zone of the office space. The black line represents the heating and cooling setpoint temperatures, whereas the green line represents the outside air temperature. Although the temperature in the core zone, which is not exposed to the external environment, is higher than that of the temperature in the perimeter zone, the temperatures in both spaces do not reach the set temperature in both the summer and the winter representative days. The installation of additional HVAC systems is, thus, necessary.
Figure 5 presents the indoor air temperature pattern after the installation of the VRF-HP

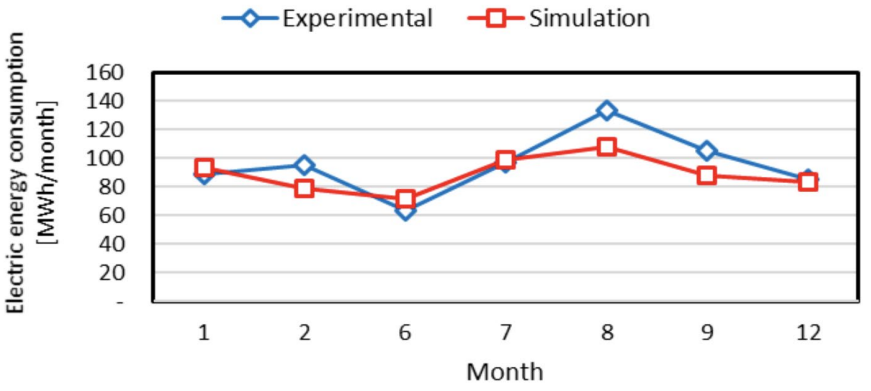

Figure 3. Comparison of the actual monthly electric energy consumption and the simulation results

system. Because of the additional VRF-HP system installed, indoor air temperature reached the heating and cooling setpoint temperature for both the winter and the summer representative days.

2.2. Strategies for optimal operation of three different HVAC systems

This section compares and analyzes the energy consumption of four different cases to suggest strategies for the optimal operation of three different HVAC systems. The four cases are as follows:

- Case-1: Central HVAC system only (current HVAC system);
- Case-2: Central HVAC as main system and VRF-HP as secondary system (sequential);
- Case-3: VRF-HP as main system and central HVAC secondary system (sequential); and
- Case-4: VRF-HP system and central HVAC system work simultaneously (uniform).

The sequential method (Case-2 and Case-3) is the main system handles all the loads. When the main system cannot handle all the loads, it means that the load is larger than its capacity. The secondary HVAC system handles the remaining heating or cooling loads.

The Uniform method (Case-4) is that when heating or cooling loads occur, all the HVAC systems operate at the same time, regardless of the amount of the loads.

Before analyzing the electric energy consumption and the district heating consumption, we describe the energy resources that the central HVAC system and VRF-HP system used. District heating is currently used for both heating and cooling in the target building. Hot water is sent directly to the heating coil in the FCU and air handling

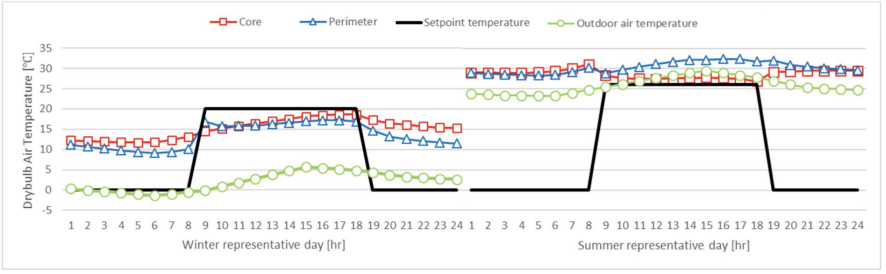

Figure 4. Comparison of indoor air temperaturas for the winter and the summer representative days

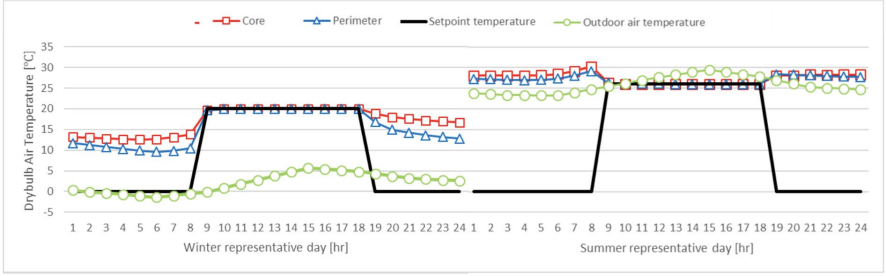

Figure 5. Comparison of indoor air temperature for the winter and the summer representative days after VRF-HP system has been installed

unit (AHU) to provide hot air in the building. For cooling, hot water is sent to the absorption chiller to be cooled through evaporative cooling. Because of these mechanisms, the target building uses district heating not only during the heating season but also during the cooling season. As regards electric energy, the VRF-HP system consumes electric energy to provide hot air and cold air to the zone. The central HVAC system also consumes electric energy for the fans, pumps, chillers, and FCUs. The operating hours of each system varies, depending on the load distribution method. It is essential to maintain a high part-load ratio (PLR) by ensuring the efficiency of the system so that less district heating or electric energy is consumed. Depending on the system's operation hours, it affects district heating, and electric energy consumption.

Central HVAC system information was entered in the other three cases based on the actual data and values calculated in Case-1. Figures 6 and 7 show the monthly electric energy consumption and district heating according to the load distribution method.

Central Only in the figure refers to Case-1, where only the central HVAC system is operated. CEN-VRF refers to Case-2, where the central HVAC system is the main system, while the VRF-HP system is the secondary system. VRF-CEN refers to Case-3, where the VRF-HP system is the main system, while the central HVAC system is the secondary system. Uniform refers to Case-4, where the central HVAC system and VRF-HP system are operated simultaneously. Case-1, which operates only one system, is represented by lines, whereas Case-2, Case-3, and Case-4, which operate two systems, are represented by boxes.

The analysis confirms that the indoor air temperature of all the cases, except Case-1, reached the cooling and heating setpoint temperature (see Section 3.1). This finding indicates that the VRF-HP system handles cooling and heating loads that the existing system (i.e., central HVAC system) cannot handle. Although Case-2 handled more cooling and heating loads than Case-1, the annual electrical energy consumption of Case-2 is lower than that of Case-1. This is due to the characteristics of the HVAC system of the target building, which circulates indoor air without introducing outdoor air.

Before the VRF-HP system is installed in Case-1, indoor air temperature does not reach the heating and cooling set temperatures. Higher air temperature than cooling setpoint temperature is, thus, introduced into the HVAC system during the cooling season, and lower air temperature than heating setpoint temperature is introduced back into the HVAC system during the heating season. In Case-2, where the VRF-HP system is installed, indoor air temperature reaches the cooling and heating setpoint temperatures. Compared with Case-1, lower air temperature is introduced back into the HVAC system during the cooling season, and higher indoor air temperature is introduced back into the HVAC system during the heating season. Case-2, therefore, consumes less electric energy than Case-1 due to the difference in return air temperature. This also affects the district heating consumption because of the same reasons: The temperature differences between return air temperature and supply air temperature in Case-2 are smaller than that of Case-1. This explains why Case-2 consumes less district heating than Case-1.

We also compared Case-2 with Case-3, where indoor air temperature reaches the cooling and heating setpoint temperatures, and only the system sequence is different. In Case-2, where the VRF-HP system is the secondary HVAC system, the central HVAC system covers loads as much as the central HVAC system can handle, and the VRF-HP system only operates when the loads remain. This explains why the electric energy consumption in Case-2 is less than that of Case-3, where the VRF-HP system is the main system.

In other words, when the load is low, the main system takes care of all the loads. For Case-2, the main system is the central HVAC system, while for Case-3, it is the VRF-HP system. As such, while the VRF-HP systems installed in Case-2 and Case-3 have the same capacity, the operation hours of VRF-HP in Case-3 are more than that in Case-2. Case-3, therefore, consumes more electric energy than Case-2. On the contrary, the operation hours of the central HVAC system in Case-2 are more than that in Case-3 since operation hours of the VRF-HP system in Case-3 are more than in Case-2. As such, Case-2 consumes more district heating than Case-3.

In Case-4, the VRF-HP system and the central HVAC system operate simultaneously when a load occurs, which means that both systems operate at low PLR, which lowers the efficiency of the system. The electric energy consumption in Case-4 is, therefore, higher than in Case-2 and Case-3. Notably, in Case-4, the VRF-HP system is responsible for 50% of the load, which requires more capacity than that installed in Case-2 and Case-3.

Considering both district heating consumption and electric energy consumption, Case-2, where the central HVAC system operates primarily, has less electric energy consumption than Case-3, where the VRF-HP system is the main system. However, because the central HVAC system is the main system, Case-2 uses more district heating energy than Case-3.

As regards all energy consumption, Case-3 consumes less energy than Case-2.

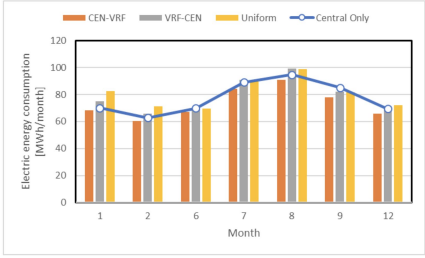

Figure 6. Comparison of monthly electric energy consumption in each caseHP system has been installed

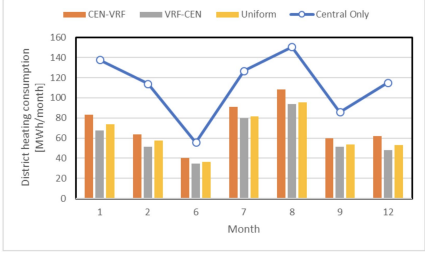

Figure 7. Comparison of monthly district heating consumption in each case

CONCLUSION

The purpose of this study is to identify the capacity of additional HVAC systems, ensure indoor thermal comfort, and propose an energy-efficient HVAC operation strategy for buildings with HVAC systems that do not have sufficient capacity.

The proposed load distribution method in this study is to operate the VRF-HP system as the main system and the central HVAC system as a secondary system (Case-3). In this case, the required installation capacity of the VRF-HP system is smaller than in the uniform method (Case-4), and the energy consumption is less than that of both the existing HVAC system (Case-1) and Case-2, which has a different strategy.

In the future, we will consider factors other than the HVAC systems, such as windows and shading systems, to reduce building loads, and we will suggest the optimal HVAC system installation capacity and control method for the minimized building loads.

PAPER #5.01

MAPPING THE CITY: DATASCAPE AS A TOOL FOR REPRESENTING THE INVISIBLE

Başak Uçar[a]
[a]TED University, Ankara, Turkey

ABSTRACT

Being an abstract system that translates and reconstructs the real phenomena, map had a long history of recording and interpreting the data. Practiced with different techniques in different periods and contexts, it has always been considered as a preeminent way of collecting, organizing and representing the data. However, map also inherits the potential of representing more than the reality and denotes new and unacknowledged conditions, which initiate the use of maps as generative tools that mediate between real and possible configurations.

Advances in technology and the use of digital design tools initiated a radical shift in communication and mapping techniques, which enabled to acquire, interpret and use complex data. Defining a shift in the conventional mapping practices, this contemporary approach of working with big and complex data engages with what is 'unknown', 'invisible' or 'discreet'. This shift necessitates the acknowledgement of alternative ways of examining and conveying information as well as its visualization. 'Datascapes' are considered as multilayered and multidimensional representations of complex data, which not only represent the data visually or numerically, but also inherit a particular 'eidetic argument'. Since they hold the data in an interpretative manner, they stimulate the designer's creativity and opens up new grounds for explorations. However, datascapes are not static representations confined with the two dimensional representation medium, rather may be configured and represented in various forms, which can be updated simultaneously and result in ephemeral maps of complex matters. These maps can represent the ever-changing relations and ever-expanding data, and can be used to map the visible and invisible data of the contemporary city.

KEYWORDS

Mapping; datascape; representation.

INTRODUCTION

Being an abstract system that translates and reconstructs the real phenomena, map had a long history of recording and interpreting the data. Practiced with different techniques in different periods and contexts, it has always been considered as a preeminent way of collecting, organizing and representing the data. Besides its conceptualization as a visual instrument (Corner, 2011) for annotating and exposing the information in an organized and readable manner, map is also embraced as a tool for reading the visible or invisible information.

Although associated mostly with the graphical representation of a city, maps are also used for understanding things, conditions, processes or events (Harley and Woodward, 1987), which facilitates their use as tools rather than mere graphical representations. Going beyond the reproduction of a bird eye view of the city that provide layers of geographical information, maps help to understand the complexity of the urban conditions and provide different layers of data. Mapping practices that achieve the graphical integrity and consistency of data interpretation enable the understanding of

existing relations and realities of the situation/site/event/processes through various layers of information sets.

However, a map also inherits the potential of representing more than the reality and denotes new and unacknowledged conditions, which initiate the use of maps as generative tools that mediate between real and possible configurations. James Corner identifies mapping as a creative activity, which both reveals and realizes the hidden potential through uncovering realities, even the unseen or unimagined ones (Corner, 2011). Practices that consider the map as a creative tool for reading and understanding the conditions, rather than an operational tool of measuring or defining the existing conditions has the potential of activating new readings. Corner differentiates these two approaches and in reference to the statements of Gilles Deleuze and Felix Guattari, he labels the maps that reproduce the already known and visible as *tracings* (Corner 2011). In his main reference for this differentiation Deleuze and Guattari states that: 'What distinguishes the map from the tracing is that it is entirely oriented toward an experimentation in contact with the real. The map does not reproduce an unconscious closed in upon itself; it constructs the unconscious' (Deleuze and Guattari, 2004)

Therefore, in order to reveal the potential of the map and to use it as a productive instrument, it is necessary to go beyond the routine of collecting, recording, assembling and representing the visible conditions and to appreciate the reading of the invisibles. Overcoming the limitations of the tracings and activating the new readings that reveal the invisibles enrich the mapping practices and expose the potential of a map as an operational and creative instrument.

1. CONTEMPORARY DRIVES

Advances in technology and the use of digital design tools also support the conceptualization of the map as a creative instrument, which embraces and exposes the invisibles in mapping practices. The radical shifts in communication and mapping techniques, as well as increased capabilities of gathering, storing and processing information enabled to acquire, interpret and use complex data. Altering the conventional mapping practices, this contemporary approach of working with big and complex data engages with what is 'unknown', 'invisible' or 'discreet'. This shift necessitates the acknowledgement of alternative ways of collecting, processing and conveying information as well as its visualization.

Computers and their variances are embedded the in all aspects of our lives in the recent years as a consequence of the miniaturization of the computer hardware, maximization of computational and storing capabilities of computers, expansion of network capacities, as well as the development of communication manners. Urban environments are occupied with data collectors, processors and archives, where huge amount of data is made accessible and visible to the society and the designers. Immersed with these abilities, the contemporary city gains the ability of storing and sharing its data through various layers. Massive amount of data is stored, processed and conveyed continuously since the cities are generating new and fresh data in an increasing speed and variety. The complex and big data accessed and processed by the advanced use of technology should be mapped to reveal the multidimensional view of the cities, either visible or invisible.

However, reconceptualization of mapping can be defined both as a revised practice, which is diversified with huge amount of data entry, and also can be considered as an instrument for dealing with the massive data exceeding the limits of human cognition and perception. This paper specifically focuses on the practices where mapping is used as a way of visualizing and understanding data. Through questioning how the data-driven mapping

practices of the recent years changed our definition, understanding and visualization of the city, it is aimed to discuss whether or how they differ from the conventional mapping practices. Considering the conventional and contemporary mapping practices, it is possible to assert that all mapping practices are defined though a process of gathering and interpreting objective or subjective data. However, the contemporary practices that are dependent more on the digital tools and computational capabilities of humans and devices can be asserted to provide deeper insights to the city and the actors involved in it.

The amount of available and operational data defines a dramatic shift in how humans understand, define and visualize the cities. However, changes defined through the use of data are not only in city scale and has affected all sections of the life, as data has become the 'de facto standard through which the world is ordered and understood' (Boyd and Crawford, 2012). The current tendency of understanding the world (cities, science, business etc.) and human through the data -mainly through the big and incomprehensible amount of data- necessitates the extension of humans perceptive and cognitive capabilities, which results in significant changes in the society. Although the increasing tendency for rendering the world through numbers is an ever-present debate (Scott, 1998), the scale of current data sets defines a radical change in the society and hence should be handled with a different mind set. Witnessing the difficulties of dealing with the complex and big data necessitates the adoption of a new mind set and instrumental approach, since the conventional approaches will not be effective in dealing with the multidimensionality of the large data sets.

With a specific emphasis on the city mapping practices, it can be stated that gathering, processing and visualizing the multidimensional and huge amount of data gathered and processed with the contemporary tools and models enables to focus on which was not visible in the conventional maps. During the recent years, it is aimed to work with the *unacknowledged* features of the city and introduce them as another layer of the multidimensional maps defined through the use of technological advances (Amoroso, 2015). However, such an approach to expose the city with its *visible* and *invisible* features necessitates an alternative mapping technique. Since these maps are not expected to only document the existing but also bring the invisible information to the forefront and make it visible, they should be open to unpredicted readings and interpretations (Amoroso, 2015). Hence, they should be structured different than the static and flat conventional maps and should be flexible enough to gather new data, host its interaction with other data sets and sustain its visualization.

Making use of technological advances and new modes of visualization, alternative readings can be provided through the integration of large sets of data, which in turn can also be embraced to understand these data sets. Therefore, attaining the flexibility of the map gains importance, when the continuous input from the city and its actors are considered. Since the data provided by and within the city is continuously changing and this change can be recognized, gathered, recorded by the technological habitat of the city, the mapping is also altered continuously and is never finalized. The maps defined through the computational tools and processes can represent the ever-changing relations and ever-expanding data, and can be used to map the visible and invisible data of the contemporary city.

2. AN ALTERNATIVE MAPPING_Naked City

The search for mapping the invisible features of the city or studying with unsteady and ever changing data is not specific to the contemporary approaches of the digital world. Rather, there have been various attempts of mapping the invisible, unstable, subjective and ever changing information. These maps were also questioning the available techniques of mapping and were proposing ways of widening the visual perspective to be able to visualize and manage information. A specific example of this search, which is also consider by many references as a critical shift in the history of mapping, is the concept of psycho-geographic mapping studied by Guy Debord.

Guy Debord was a key figure of Situationist International, which was an interdisciplinary organization active in Europe in the mid-20th century attempting to return the map to everyday life and to the unexplored, repressed topographies of the city (Corner, 2011). Debord defined psychogeography as: "the study of the specific effects of the geographical environment…on the emotions and behavior of individuals" (Debord, 2008) and made a series of studies on the Paris map, which were not mere representations of the cityscape. Rather, Debord's studies were reflecting the subjective inputs such as perceptions and desires of the human. *The Naked City* map was produced in 1957 by Debord through taking nineteen sections from the original map of Paris, which were reassembled in a subjective manner considering the experience and the desires of the human. Defining this work as a construct that creates a synthesis between the existing conditions and the human experience, Debord also added red arrows to the map (printed in black ink), which illustrate the "spontaneous turns of direction" between the fragments (McDonough, 1994). The fragments and the turns are all defined according to the personal experience of Debord when he wandered along the streets and alleys of the city, defining his own path through turning here and there (McDonough, 1994). Therefore, the arrows together with the fragments- reflect the desires and experience of the human through the city. The produced map is an ephemeral, subjective and personalized one, where the invisible desires and experience of the human is brought forth and opened up new discussions on different aspects of the city ranging from politics to perception.

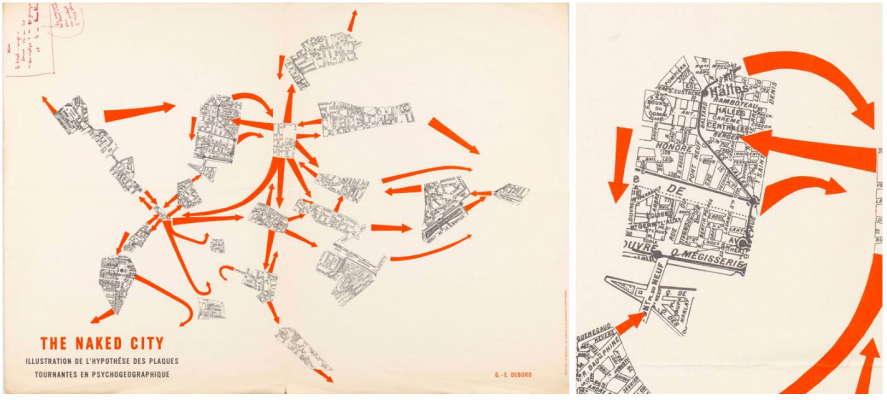

Figure 1. The Naked City map produced by Guy Debord. (1957)

3. DATASCAPES

Guy Debord's approach of considering the fluidity of the city and bringing forth its unknown features dependent on the personal and subjective inputs, initiated the studies that aim to define a deep awareness of the unquantifiable and immaterial qualities of the city. James Corner defines this approach as a creative one and outlines mapping as a process of a strategic and imaginative drawing-out of relational structures, rather than an indiscriminate listing and inventorying of conditions as in a tracing, table or chart (Corner, 2011).

Considering the complexity of the city and the relationship between the city, citizens and the society, the maps are expected to represent the dynamic relationships of the city. For that reason, they are structured to collect, interpret and represent the subjective inputs and experimental data through its multiple layers, besides the objectively constructed data through numeric and quantitative values. In this approach, maps are conceptualized as creative processes, which enable to collect, process and represent various types of data.

One significant development that initiated a radical shift in mapping processes and supported their definition as creative processes is the advances in technology and the use of digital design tools, which enabled to acquire, interpret and use complex data. Over the past few decades, maps have been re-conceptualized to support the creative processes through using the advantages provided with the digital media and computational abilities. Their further development can be asserted to initiate new techniques and definitions of mapping and widened the capabilities of the designer to investigate and interpret the urban data. Defining a shift in the conventional mapping practices, this contemporary approach of working with big and complex data engages with what is 'unknown', '**invisible**' or 'discreet'. These 'new' maps, which enable the representation of the invisibles of the city through the multilayered data, are considered as alternative approaches that re¬-vision and rethink the mapping and urbanism of the contemporary city (Amoroso, 2010).

This shift necessitates the acknowledgement of alternative ways of examining and conveying information as well as its visualization. 'Datascapes' are considered as multilayered and multidimensional representations of complex data, which not only represent the data visually or numerically, but also inherit the potential of influencing the mapping and design processes (Lootsma, 1999). Therefore, datascapes hold the potential to go beyond statistical descriptions and serve as creative grounds for designers. James Corner describes datascapes as representing "objectively" constituted data through numbers, quantities or facts in knowingly selective ways to construct or suggest new spatial formations (Corner, 1998). He differentiates datascapes from the quantitative maps and states that 'they are designed not only to reveal the spatial effects of various shaping (eg, regulatory, zoning, legal, economic, and logistical rules and conditions), but also to construct a particular eidetic argument" (Corner, 1999). Questioning the quantitative and creative potentials of mapping, the term eidetic is used by Corner to discuss the works that represent and mimic the reality and the ones triggering the creativity. He defines eidetic as referring "to a mental conception that may be picturable, but may be equally acoustic, tactile, cognitive, or intuitive" which is "unlike purely retinal impressions of pictures, eidetic images contain a broad range of ideas that lie at the core of processes of creativity" (Corner, 1998) Through point out the potential of eidetic conditions to engender, unfold and participate in emergent realities, Corner underlines their stimulating power for creativity.

Referring to WJ. T. Mitchell's comparison of a picture and an image, where the difference between a specific kind of visual

representation (the 'pictorial" image) and an image (verbal, acoustic, mental images) were discussed, Corner identifies the maps as images holding eidetic arguments (Corner, 1999). Through these arguments, the designer can both represent the reality and also reformulate given conditions, which may lead to new interpretations and innovative solutions (Corner, 1999). Since these eidetic arguments facilitate the subjective inputs introduced of the designer, they enable and welcome alternative reading and interpretations of the conditions. With this potential, they differ from the mere visual representations of quantitative maps and enable the *imaging* of data in instrumental ways (Corner, 1999).

Use of digital medium also affected its instrumental use and enabled multi-layered and continuous data input, which enable to render complex interrelations and interactions. They are not static representations confined with the two-dimensional representation medium, rather may be configured and represented in various forms. They can represent the ever-changing relations and ever-expanding data, which can be updated simultaneously and result in ephemeral maps of complex matters. They also hold the data in an interpretative manner, which stimulate the designer's creativity, enable they future readings and open up new grounds for explorations.

In the late 1990's, when the influences of the shifts defined through the use of digital medium and increased computational capabilities were asking for reassessment of the tools and approaches in use, Dutch architectural firm MVRDV questioned the conventional mapping processes and experimented on datascaping. Their approach to map the urban phenomena through datascaping was a provocative one, which extended the definition of mapping through the use of digital medium. In their publication Metacity/Datatown, MVRDV questioned the contemporary conditions of the city and the inadequateness of the ways used by designers to understand the data provided by the city that exceeds the perception and comprehension of the human. Considering a fictional and extreme scenario, where the current population of the Netherlands was multiplied to increase the data produced by the city, they studied data of the city and / city as data. Through using the qualitative

Figure 2 (left). One large red cube is created measuring over one and half kilometers on edge to represent a massive volume that would contain all the inhabitants of Datatown.
Figure 3 (right). Landscaped datascapes, created by waste emerge as hills and mountainous forms, which create a new landscape.

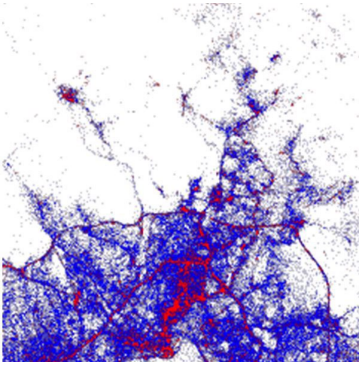
(visual approaches) to signify the quantitative (numerical data) data, MVRDV studied the scenario in two scales where Metacity relates to the whole world and Datatown relates to the Netherlands (Amoroso, 2010). The data gathered through the analysis of the spatial, social and economic consequences of the proposed population was studied both numerically and visually (Amoroso, 2010). Statistical analysis and use of numerical expressions were considered as essential tools to grasp the complexity of the data available, document and process it. However, the visual expression of these numeric values to attain a comprehensible form that abstracts the multiple layers of data in a powerful and yet informative way and also stimulates the creativity of the process. The visual images produced in Metacity/Datatown project can be considered as eidetic arguments, which initiate future scenarios of the city through imaging the statistical data in visual form. In this respect they are differentiated from the conventional maps, which picture the reality through representations.

Considering the uncanny relationship of the maps with real, where they are defined to be abstractions, that initiate new conditions and reading, datascapes provided by MVRDV can also be regarded as maps (Amoroso, 2010). Through considering the extreme scenarios producing complex and multidimensional data, these datascapes deal enable to translate the changing conditions and make future reflections on the urban situations. Processed digitally, these datascapes both reflect the reality and also define an uncanny relationship with the real, which liberates the designer to make predictions, speculations and new readings.

With the increased computational capacity of the twenty first century, map designers also integrated subjective and experience based data, which can be considered as a consequence of the conception of city as a multi-layered entity. Rooted from the experience based maps of Situationists, the contemporary maps have the potential of being datascapes representing not only the visibles and invisibles of the city as a physical object, but also consider it as a complex and emergent system generated through dynamic relations (Urry, 2005). In this system, the data of the human also gains importance, since they are one of the actors of these dynamic relations. These mapping practices ¬-that consider the experiences of the humans and consider the data provided by them within the multiple layers of the map- inherit the potential of providing new readings of the city. They enable to draw the invisibles of the city and explore its immaterial and embodied data.

One significant example of these experimental maps is produced by Eric Fischer, which visualizes the relationship between the social media posts and the location of the author. Introducing Geotagger's World Atlas project, Fischer aims to uncover how people interact with the cities and uses geo-tagged photographs of the cities or tweets in social media. Focusing on a specific period, Fischer attains a huge amount of data to be visualized, which provided the invisible interaction patterns and new data layers of the cityscapes.

Such practices enable to draw the invisibles of the city and explore its immaterial data, which focuses on the relationship between the individual and the city. These subjective mapping practices can also be considered as datascapes, since the datascape holds the flexibility of holding any kind of related with geography, sociology, economy, traffic or personal inputs. They highlight the subjective input from the human and investigate the relationship between the human and the space through analyzing the subjective aspects related with space (emotions, memories, personal experiences etc.) (Perkins, 2009). These practices benefit from the visual power of the mapping to abstract and comprehend the data, communicate with the designer/reader and to initiate new readings of the relations. The data provided



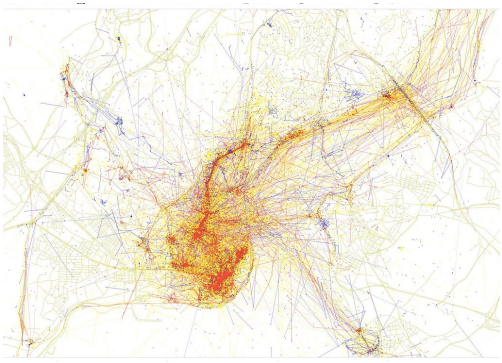


Figure 4 (left). The map visualizes the tweets of residents in İstanbul (identified with blue spots) and out-of-towners, namely the tourists (identified with red spots).
Figure 5 (right). The map visualizes the photographs shared by of residents in İstanbul (identified with blue spots) and out-of-towners, namely the tourists (identified with red spots), where yellow one might be either.

by the subjective definition may reveal the invisible relations, evoke unexpected readings and produce visual images triggering the creative processes of mapping. This aim of investigating the relationship between the human and the city, recalls the psychogeographic maps of Situationists, where it is possible to trace the similarities between these two approaches and define the datascapes including subjective data inputs as arrays of these psychogeographic maps.

With all types of data input the maps turns out to be multilayered and represent the collective invisibles of the society. Since the data becomes available and accessible with the advances in technology, its use in various phases of design and decision-making processes increase significantly. This change in the state of data enabled to map the geospatial data collected from the users, which diversifies the subjective inputs to the datascape and also shift the scale of the data set drastically. Compared to the psychogeographic maps of Situationists, where one or a limited number of subjective data were mapped, contemporaray studies hold the potential of gathering, analyzing and visualizing data provided from various subjects.

An up-to-date example of this approach is provided by Bits'n Bricks office where location mining and web scraping were used to gather data in urban scale for İstanbul. Collecting the publicly avaliable data retrieved from the urban sources they collected the data of the shared images by tourists (through their Flickr accounts) in İstanbul and tried to map the attraction points (Bits'n Bricks) They also provided an association between the routes provided by mobile map applications and the attraction point-instagram post maps (Figure 6). The produced maps read the geospatial data and provide insight on the visibles and invisibles of the city.

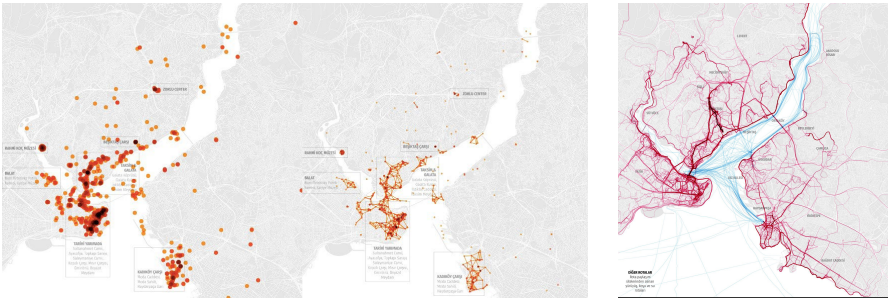

Figure 6. Mapping the attraction points for tourists in Istanbul, through processing the data provided by shared photographs.

CONCLUSION

Contemporary mapping practices that make use of the advances of the technology enable to gather, process, and visualize huge amount of data, where the ubiquitous data production feeds the dataset simultaneously and continuously. In line with the developments in the technology, changing lifestyles also motivates us to produce and share the data and hence become a part of the big data pool. Continuous update of the data sets to be considered in mapping also changes the validity of the mapping, since it evolves with the data input. Their short-term validity can be considered as an important shift, since the arguments and representations expire rapidly. These shifts in the definition and use of data necessitate the reconsideration of conventional mapping techniques to respond to these changes. Although alternative mapping techniques have been applied throughout the history, the experienced shifts request a different mindset and processes to be use in mapping practices.

In order to develop a new approach that may enable to understand how the city functions in line with its citizens, the conventional mapping practices should be updated to hold multiple layers of information; including the unexplored, speculative and subjective ones. These multi-layered studies necessitate going beyond being mere visual representations of the existing realities and trigger creative processes and initiate interpretations of the data sets. However, the gathered data from the collective and multiple sources are usually raw data, which has to be filtered, organized, categorized and read, which requires an interdisciplinary group of expertise. Therefore, mapping cannot be an individual practice but should be considered as a process guided by a group of experts.

PAPER #5.02

INTEGRAL DESIGN FOR URBAN TRANSFORMATION TO A SMART CITY CORE

Marios .C. Phocas[a], Maria Matheou[b]
[a]Department of Architecture, Faculty of Engineering, University of Cyprus, Cyprus
[b] Institute of Lightweight Structures and Conceptual Design, Faculty of Civil and Environmental Engineering, Stuttgart, F.R. Germany

ABSTRACT

Urban unities of sustainable development may act as transformers of knowledge and technological advancement achieving thus improved social, working and living conditions to their inhabitants. A representative case study of such development refers to the design proposals made in Spring Semester 2017, in the frame of the design studio with an emphasis on technology in the 6th semester of undergraduate studies in Architecture at the University of Cyprus. The design objectives referred to the regeneration of a unified core of Nicosia through the creation of flexible building units of industrial research and technological development, envisioned to act as urban transformers and interaction nodes with the local and global communities of labour, research and production. The presently existing decentralization of the city, as well as the diversity of social groups, lack of production, labour and green areas within the city core have so far led to unfavourable conditions with regard to a respective sustainable urban, architectural and social development of the old city centre. Nine design proposals presented in the current paper refer to timely variant activations of the city core bridge connections with the new city areas, aiming at the transformation of the city core into a smart urban area. The building units are expected to provide flexible and multi-use spaces, where different researchers may work at different time periods. Pedagogically, of equal high importance was the design requirement for the proposed buildings to comprise symbolically prototypes of technological development of respective activities and tectonic structures, while displaying the interrelated areas of function, construction and energy efficiency. The study further demonstrates that different activation scenarios of the buildings and the interactions with the city-core flows of activities are possible.

KEYWORDS

Urban regeneration; smart cities; urban and building transformability; architectural technology; integrated architectural design.

INTRODUCTION

Smart cities have become a landmark in urban planning. They are the result of knowledge-intensive and creative strategies aiming at enhancing the socio-economic, ecological, logistic and competitive urban performance. Smart cities are based on a promising mixture of human capital (e.g. skilled labour force), infrastructural capital (e.g. high-tech communication facilities), social capital (e.g. intense and open network linkages) and entrepreneurial capital (e.g. creative and risk-taking business activities).
Central paradigm of urban transformations to smart regions is the provision of innovation through networking. The key driving force of technological and economic progress essentially depends on cooperation and interaction between firms and different scientific and societal institutions. Such cooperation forms and the associated

personnel and information technological interaction are generally termed "network" (Sydow, 1992), primarily based on the concept of local or regional sustainable developments of so-called regional milieux (Läpple, 2001). The latter can be described as spatial production and actor systems characterised by collective learning processes. For urban development processes, milieux are primarily amplifiers of the city life and productivity. These can generate synergies and thus strengthen regional innovative resources (Läpple, 1994). In this frame, innovation processes are enhanced by local and global cooperation activities among individual research and development institutions and by the specific embedding of operations in the common urban context.

Research and development institutional knowledge-exchange links are important for increasing a city's knowledge economy (Acworth, 2008). In this framework, local proximity and geographic clusters have been important determinants in creating innovative cities, since knowledge and production are generated and realized more efficiently via local proximity and clustering (Audretsch and Feldman, 1996; Audretsch, 2002). These knowledge-production clusters (spaces) enhance the innovativeness of a region. Thus, such urban areas form local spatial foundations for knowledge and local production activities to flourish by bringing out the importance of knowledge- and skills-based activities, knowledge exchange, and spillovers in urban localities (Olcay and Bulu, 2016).

In parallel, the global economy has shifted from an industrial, goods-centered one to an innovation, service-centered one. This occurred gradually as innovative technologies, methods, and concepts evolved over time (Davenport et al., 2006). In today's innovation economy, new value is created through knowledge and intellectual capital and new entrepreneurships are the main drivers of wealth and economic growth, as opposed to the solely traditional physical assets and owners of the industrial economy. While rapid technological developments and increased globalization have forced the economic activity of traditional industries to move to low-cost countries, as Audretsch (2002) suggests, knowledge and innovation are less likely to be transferred across geographical spaces; on the contrary, they concentrate geographically, forming innovation districts and spaces, and eventually turn into innovative cities. Yigitcanlar et al. (2008a) call these urban innovation spaces "knowledge community precincts", mostly referring to place-centered knowledge and innovation clusters. These clusters comprise high-tech manufacturing of knowledge-intensive industrial and business sectors existing in a mix of urban life and culture within central urban locations (Yigitcanlar et al., 2008b). Along these lines, Kline and Rosenberg (1986) define the chain-linked model consisting of basic scientific research, product and process development, and commercialization as the three fundamental stages of the innovation process, where innovation can be initiated at any stage with inputs from internal stages and spillovers. The development of formal relations between research and development with urban unities results in mutual benefits.

In reflecting upon the approach of embedding research and development unities within an existing urban context, a representative case study refers to the design proposals made in Spring Semester 2017, in the frame of the design studio with an emphasis on technology in the 6th semester of undergraduate studies in Architecture at the University of Cyprus. The design objectives referred to the holistic regeneration of a unified core of Nicosia through the creation of flexible building units of industrial research and technological development, envisioned to act as urban transformers and interaction nodes with the local and global communities of labor, research and production. In the

following section, the city core of Nicosia will be briefly described. Subsequently, nine building proposals, a possible scenario of individual building units' activation and interaction with each other and the city core will be briefly presented.

1. NICOSIA CITY CORE

The walled city of Nicosia is an example of medieval town planning, and dates back to the Venetian period (1489-1571). During this time, of major concern was the entity of the urban form rather than the internal structure: the city's Renaissance walls with their 11 bastions and three gates were built to consolidate the town, which had revealed a dispersed character. In this frame, the city core has ten connection links to the new city. The walled city has an area of approximately 200 ha, and comprises the oldest part of the city, symbolizing the geographical and historical significance of Nicosia and Cyprus as a whole. The city core was declared a conservation area within the Nicosia Master Plan in 1989.

Today, Nicosia faces serious and complex problems that are largely caused by the existence of the dividing line, which has contributed to boosting development to the south and the region, and to the general downgrading of the walled city and the wider area of the city centre and the suburb areas along the dead zone. In these areas, there is a degradation of the quality of life and the urban environment, economic stagnation and population decrease. The initial concentration of services, commerce, administration and other core activities in the city centre encouraged the development of a radial road network that functionally results from the existence of a single employment center. Dispersal of employment opportunities and residential areas to wider areas followed in the last decades.

The design of building units of Industrial Research and Technological Development for the Nicosia Core in the Spring Semester 2016-17 aims at the holistic regeneration of a unified core of Nicosia. It is proposed that the

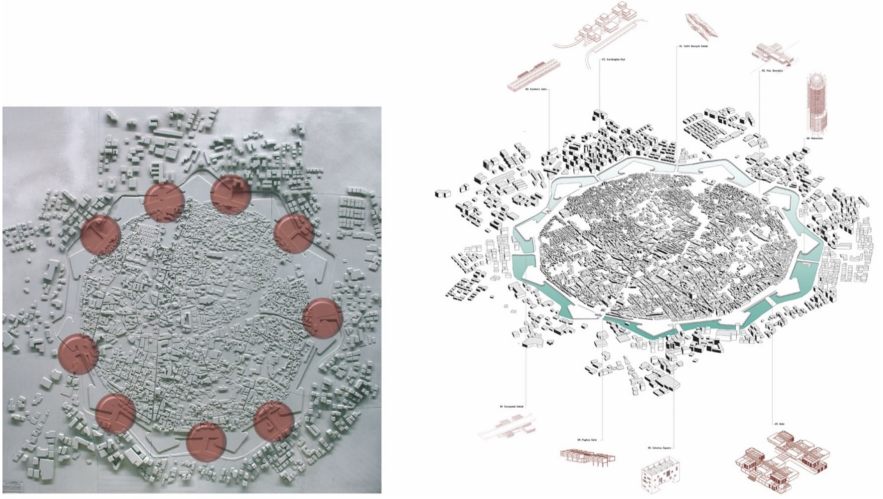

Figure 1. Nicosia city core with bridge connections to new city and corresponding building units

city core transforms into a smart wider urban area with time variant activation of nine bridge connections with the new city of Nicosia through the addition of "temporary" in each case, building units of industrial research and technological development (Fig. 1). In principle, the buildings comprise nodal points of research and technological development in the wider area of south-east Mediterranean, whereas the core of the buildings supports the areas within the city core.

2. BUILDING UNITS

The buildings units' proposals have been developed on the basis of an integrated architectural design approach, i.e. the development of the respective areas of the building morphology, structure, construction and environmental/energy design (Phocas, 2017). In an initial stage the proposed urban space, the functional zones of each building and the structure have been investigated. With the development of a general morphology of individual elements or the entire building, the formulation of an abstract design concept and the coordination between construction, function and form have been pursued. The architectural design has been further developed according to the functional disposition, the structure and the building envelope. Subsequently, the energy efficiency of the building has been investigated. The final stage of development consists of the construction design of the proposed elements and systems in detail.

The building units have a total area of 2000 m² and they are expected to provide flexible and multi-use spaces, where different researchers may work at different time periods. In all cases, of equal high importance is the design requirement for the proposed buildings to comprise symbolically a prototype of technological development of contemporary structures, or and of their internal special functional character, at aesthetic and morphological level, and while displaying the interrelated areas of function, construction and energy efficiency.

The building unit at Archbishop Makarios B bridge is directly positioned on the moat level of the city walls connecting the old with the new city. It consists of a tall skeleton structure acting as an outrigger system, with the prefabricated units of private and public usages plugged into (Fig. 2). A central atrium hosts vertically the exhibition of the building,

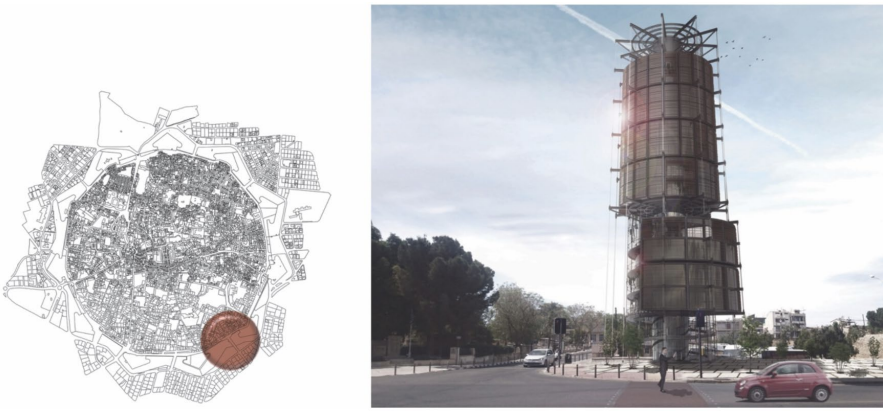

Figure 2. Building unit at Archbishop Makarios B

and all functional levels are accessed on the periphery of this open space through a ramp. Thus, the building develops vertically at the specific site.The building complex shown in Fig. 3 is positioned on both sides of the Dorou Loizou bridge. The building sections are interconnected at the moat level of the city walls underneath, through public spaces. At the street level, the building offers on both sides a window of related exhibits. On the level above, private and semi-public research spaces are accommodated. The building complex forms a gate for the main commercial circulation vain to the old city core.

The building at Solomou square extends from the moat level of the city walls over the level of the square in six floors (Fig. 4). The semi- and public areas of the center are distributed over the height, whereas the private areas are only visible by the public. The structural disposition enables openings at the floor levels, so that the functions are interrelated throughout the building. The circulation is achieved through a ramp on the periphery. A glass envelope with integrated adjustable sun-protection elements enlightens the appearance of the building. hus, the building acts like a showcase of its contents and activities in attracting the public flows within from the main bus stations at the site.

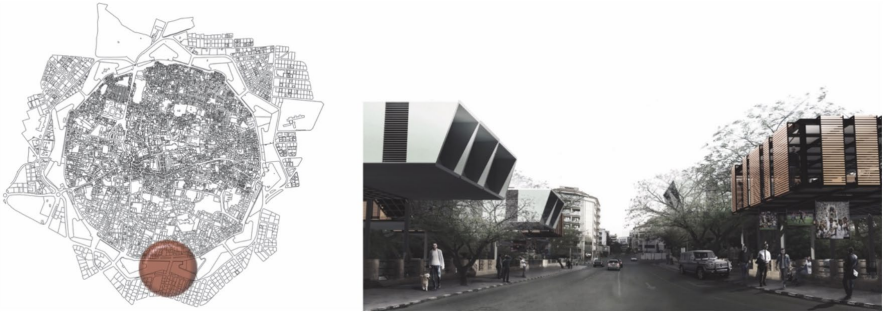

Figure 3. Building unit at Dorou Loizou

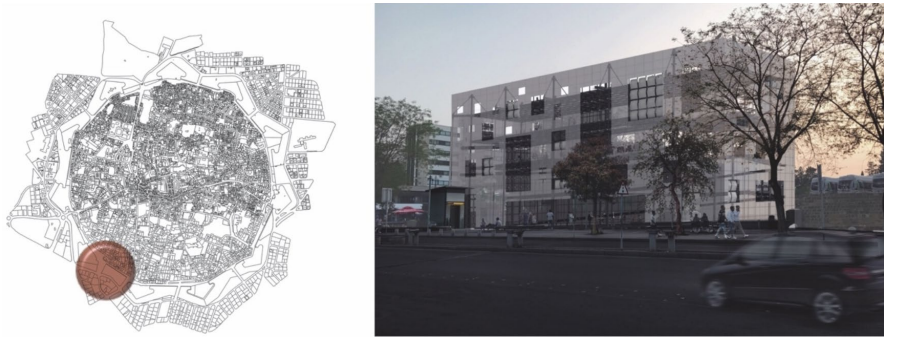

Figure 4. Building unit at Solomou Square

The building at the Pafos Gate consists of two main sections that are connected through a corridor over the street leading to the old city (Fig. 5). The north section hosts the entrance of the complex and a glassed exhibition space. The first floor hosts the private and semi-public research spaces accessible by the visitors. The façade panel openings adjust to the functional requirements of the corresponding spaces.

The building units at Sarayonu are positioned at the moat level of the city walls (Fig. 6). The main building section is situated below the street level, and extends on one side of the moat. Deployable units adjust through their size, structure and envelope elements to the functional disposition of the program. In this case the building primarily conveys open and closed spaces within the landscape at the moat level.

Figure 5. Building unit at Pafos Gate

Figure 6. Building unit at Sarayonu

The building unit at Kerynia Gate bridges two opposite sides of the city walls with the connecting street to the old city extending underneath (Fig. 7). The public functions are distributed within a main glazed open space. The private spaces are contained in prefabricated lightweight units plugged into the main structure on the back longitudinal side facing the new city. The building acts as a gate to the old city exhibiting the public activities within the old city area.

The building unit at Saracoglu Myd develops along the main connecting street to the old city (Fig. 8). A unified space is placed below the street, containing public spaces. The private spaces are placed on the upper levels of the complex. Three cores with vertical circulation elements connect the cantilever functional units above the street level. The latter consists of truss tubes connected to the cores. The building complex is primarily envisioned to activate the urban area at the moat level of the old city.

Figure 7. Building unit at Kerynia Gate

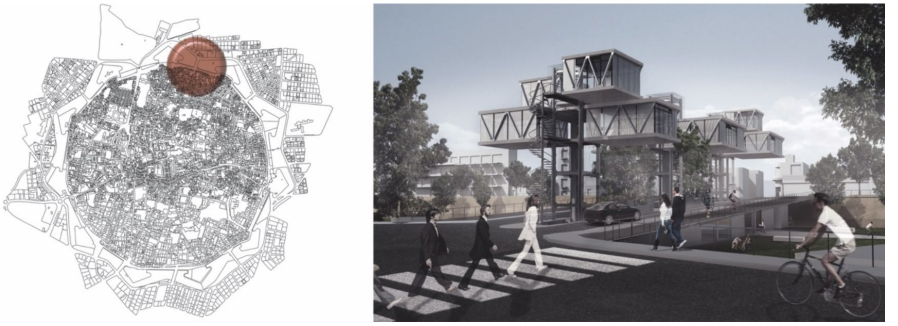

Figure 8. Building unit at Saracoglu Myd

The building unit at Sehit Huseyin Ruso is positioned on the street connecting both city sides, and it transforms the area to a pedestrian zone (Fig. 9). The building is developed in two autonomous sections interconnected at the street level. Each section consists of a mega truss tube, hosting two main functional levels. The public functions are mainly concentrated at the ground level, while the private ones, at the levels above. Thus, the building acts as a passageway at the site.

The building core unit at King George B is grounded at the moat level of the city walls on one side of the connecting street, and it extends over three levels. The building core hosts the exhibition of the center and the vertical circulation elements. The semi-public areas are hosted in prefabricated units positioned at street level and above, and the private research areas, within the main cantilever above the street. The building bridges the street, whereas a steel staircase connects the main cantilever with the park underneath. The building disposes a gate to the old city core (Fig. 10).

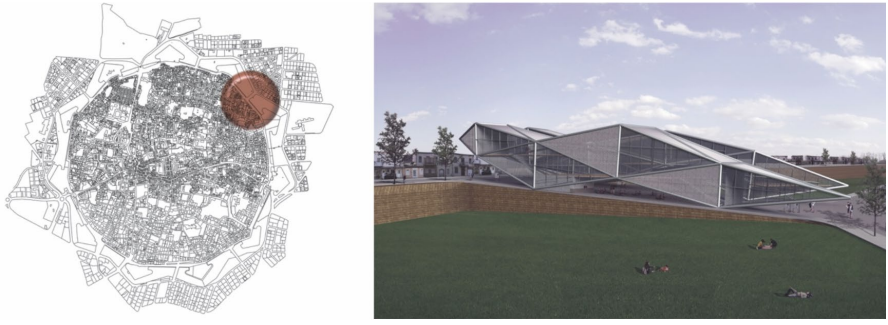

Figure 9. Building unit at Sehit Huseyin Ruso

Figure 10. Building unit at King George B

2.1. Urban activation scenarios

The development of the building units has been based on modularity, light-weight and mass-fabrication to -customization of the components. The buildings' articulation derives from the context of the site and favors a high degree of flexibility of the units' composition. At the same time, the proposals support sharing and networking of functions among different building units within the city grid and by extension, with local urban areas. Different urban activation scenarios may emerge according to the building units realized at different bridge connections to the old city. A case example is shown in Fig. 11, whereas four buildings are activated at a specific time, comprising further a corresponding urban network of research and development within the Nicosia city core. Based on such urban activation scenarios, the old city life and productivity are enhanced. In parallel respective circulation paths, labour, open space and green areas of the city are developed. Further related developments within the old city core are expected to arise due to further urban activations through different buildings' realization and interaction.

CONCLUSION

The current paper has presented design proposals of flexible building units of industrial research and technological development for the city core of Nicosia. In view of the current situation of the city centre, primarily characterized by a degradation of the quality of life and the urban environment, economic stagnation and population decrease, the units are envisioned to act as urban transformers and interaction nodes with the local and global communities of labour, research and production. At the building level, aspects of modularity, light-weight and mass-customization favor the achievement of flexibility for an effective time-dependent interaction of the units at a global and local level, especially within the specific urban context. The architecture developed, provides a particular vision of the future of the area while relying on contemporary technology, and supports flexibility, transformability and adaptability in macro and micro-scale. By extension, embedding research and development institutions within the walled city of Nicosia may further enhance its regeneration and sustainable development. Further investigations of the proposals refer to the socio-economic impact of mixed usages introduction at the urban scale and the application of technology for the achievement of a sustainable regeneration of the old city core.

PAPER #5.03

ARCHITECTURAL ROBOTS: RETHINKING THE MACHINE FOR LIVING IN

Rachel Dickey[a]
[a]University of North Carolina Charlotte

ABSTRACT

As the appearance of robots become more prominent in the built environment, architects face the challenge of exploring design opportunities for their integration. While such a synthesis involves an interest in technological systems and kinetics, it also importantly involves alternative ways of occupying space. This paper outlines the role architectural robotics play in the advancement of the human condition by proposing novel ways of living with and within the machine. Through a critical review of architecture's relationship to the machine paired with the outline of an experimental pedagogy, the intent is to uncover ways for equipping a future generation of architects, not only capable of realizing environments embedded with feedback and dynamism, but also adept in envisioning the design of a better world.

KEYWORDS

Robots; humanism; pedagogy; occupation; feedback.

INTRODUCTION

Like the language of machines that inspired Le Corbusier a century ago, advances in artificial intelligence and robotics have raised questions regarding how these technologies change the way we both design and inhabit space. Thus, contemporary architects are inevitably faced with the challenge of rethinking the creative and technological limits of the discipline. Greg Lynn stresses the need for such developments, when he writes:

> Rather than merely outfitting buildings with technology [and...] rather than implanting empty boxes with artificial intelligence or retrofitting our cities for driverless vehicles, architects should [...] integrate large scale robotics into buildings and urbanism at the very inception of their creative and critical processes [...] to realize not just dynamism and interactivity, but envision new kinds of spaces and structures with a technological integrity that challenges the static status quo. (Lynn 2016, 16).

From this provocation a set of key questions arise asking, how might we, as architects, become active participants in exploring ways robotic technologies are integrated into the built environment and what are the spatial implications and architectural ideas that might emerge from their integration?

The architectural robot legacy, in both its historical and contemporary context, provides a framework for the pedagogical experiment, outlined in this paper, entitled, the *Robot Project*. Taking heed to Beatriz Colomnia's call for radical pedagogies, which "shake foundations, disturbing assumptions rather than reinforcing and disseminating them," (2012) the *Robot Project* seeks to address transformations brought on by new technologies and an information culture. The project recognizes that emerging fields today are exploring the use computers and automation of robots in the home (domotics), in cities (urbotics), and on land (orbotics) (Somalvico 31). While Bill Gates forecasts "a robot in every home" (Somalvico 31), the former dean of architecture at MIT, William Mitchell, envisions homes not as "machines for living" but "as robots for living in" (Kapadia

2010, 48-53). It asks, will a future generation of practicing architects be prepared to address these emerging disciplinary concerns? Similarly to Walter Gropius's description of industrialization as a "'purifying agency' liberating architecture from outmoded technological as well as aesthetic values" (Picon 2014, 58-59) during modernism, the *Robot Project* recognizes that technological innovation can likewise be a driver for epistemological changes, which forces designers to think differently.

1. THE ARCHITECTURAL ROBOT LEGACY

1.1. A Machine for Living in

Importantly, the *Robot Project* is grounded in a much larger historical and contemporary context as defined through the longstanding relationship between architecture and the machine. In Le Corbusier's *Towards a New Architecture,* he envisioned a new world derived from industrialization and his infamous quote, "a house is a machine for living in" first appears. Corbusier situates the quote in the context of the airplane imploring that engineers define the problem of "wishing to fly like a bird" and in response "invent a flying machine" (1986, 113). He then questions how might we, as architects, define and solve the problem of the house. Despite the abundant reference to the machine, its application in modernism focused primarily on style rather than interest in the machine as an instrument. However, 1960's architectural discourse focused on the integration of the machine as way to explore how it might influence both the conceptualization and inhabitation of space from domestic to urban scale.

Post war thinkers like Reyner Banham called for "a restored interest in technology in terms of instrumentality" (Perry 2012, 74). For instance, in Banham's "Anatomy of Dwelling" in collaboration with François Dallegret, he exposes the relationship between technology and domestic life by pointing out that the house is so full of mechanical and electrical services that the instrumentation alone could provide shelter. These drawings acted as a provocation to architects to take a serious approach to technology. Banham also presented these ideas at the 1966 International Dialogue of Experimental Architecture (IDEA). *The Radical Pedagogy* archive describes Banham's talk stating:

> He concluded by asking whether the architect of the future would still find him or herself involved in the "enclosure business" or would instead have turned towards environmental conditioning systems of the type being developed for the space program, from life support suits, to telecommunications helmets and food "shots." (Buckley).

Banham's statement assumed that existing trends in technology would grow and urged architects to look at technological advancements as a precursor for working through the potential impacts on the discipline (Perry 2012, 74). Such early ideas of technological extrapolation focused on adaptable architecture and transformation of space as seen in the designs from many of those 1966 IDEA attendees such as Cedric Price, Archigram, and Yona Friedman. These key players conducted technological experiments that pushed boundaries in architecture and drove resultant ideas regarding ways of living.

Of course, the most notable project for the concept of a reconfiguring building embedded with responsivity was the Fun Palace (1959-1961) proposed by Cedric Price in collaboration with Joan Littlewood, John Frazer, and cyberneticist, Gordon Pask. The Fun Palace proposed a flexible and transformable building able to accommodate a variety of occupation possibilities. The building system included a user interface for reconfiguration along with the ability to autonomously suggest new spatial configurations whenever it would "get bored" with common arrangements. Price believed

providing spatial flexibility was the best way to consider a building's users and he argued that new technology "should both serve the public and further human freedom" (*Ways of Being Political* 2013).

1.2. Architectural Robots a Humanist Project

While the robot legacy in architecture reveals a trend, which exists primarily under a humanist agenda, by striving to explore alternative ways of occupying space in order to enhance the relationship between people and their environments. The exploration of technologically optimistic design practices suggest the line between social activism and a technological agenda is not so distinct. For instance, Buckminster Fuller, saw technology as "a means to redesign society" (Picon 2014, 56). His designs for the Dymaxion house and car "were not only […] meant to revolutionize the building industry, transportation and everyday life; they were also intended to pave the way for a radically different future in which men would roam free on the surface of the globe, live everywhere and fully take advantage of their intellectual capacities" (Picon 2014, 56). In the Potteries Thinkbelt project, Cedric price also appropriated mobility as a means to distribute knowledge. He proposed to occupy a railway system in order to transport and disperse knowledge with the cars behaving as mobile teaching units in addition to "inflatable lecture theaters, foldout desks, and information carrels" in order to provide a means of distributing, sharing, and cultivating knowledge outside of the static campus model (*Changing of the Avant-Garde* 2002).

Urban narratives for softer architecture of the 1960's suggested a liberation from the status quo through flexibility and choice as a means to facilitate density and the expansion of the city. Yona Friedman explored human centered design problems in his project Ville Spatiale, providing an urban infrastructure that supported flexible rearrangement, as a way of having occupants give meaning to their environment through the freedom of individual choice. While Friedman's proposal involved complexity of motion through reconfiguration, the project's focus was to promote the discussion of urban growth by providing the "fundamental right to self-expression of individuals" (*Ville Spatiale*).

Archigram's work provides multiple examples of the integration of various scale robots through the lens of fiction as a way to promote discussion that could lead to change especially different from the ever growing means of suburban life. For instance, their prototype for a house of the future in their exhibition titled, *Living 1990*, included a room with two robots to accommodate moveable services and change various states of walls, ceilings, floors, and furniture. Looking at an urban scale, Archigram's proposal for Walking City envisioned an intelligent infrastructure intended to freely roam the world making decisions about where to move based on resources and production capabilities. Such robotic interventions of the 60's from Friedman to Archigram suggest the capacity for resilient response to natural disaster and also promote an agenda for open boarders in which cities effectively relocate in support of vitality and equal access to resources for all of humanity. In response to skepticism about Archigram's ideas and their relationship to the "human factor," Hans Hollein describes both the social and political agenda behind the work when he writes, "Their ideas are always for people, for a better life for people" (Cook 1999, 6). As Hollein points out in Archigram's work, the architectural robot in its legacy interrogates both practice and culture by exploring novel ways of living with technology and each other.

While Archigram used fiction as a means to deflect questions of actualization, other key players like Nicholas Negroponte founder of the Architecture Machine Group (which later became the MIT Media Lab) sought to realize context responsive buildings.

Negroponte describes the group's vision of "a man-made environment that responds to and is 'meaningful' for him or her" (1975, ii), suggesting responsivity could provide additional significance to the built world. He also describes the goal of "humanism through intelligent machines" (1970, 7) and the desire to "conjure a world where buildings are […] animate, thinking, and emotive beings, which actively house and protect us physically as well as psychologically" (Beaumont 2015). Negroponte's experiments sought not only to promote alliances between architecture and computation, but also strove to find ways to advance the human condition by promoting a symbiosis between man, machine, and the built world.

1.3. The Speed of Society

In contemporary research and design practices, architects have been looking for ways to deal with dynamics and spatial reconfiguration. In projects such as, OMA's Maison Bordeaux in France (1998), Greg Lynn's RV Prototype House designed for the Bienniale Interieur (2012), Axel Kilian's Flexing Room exhibited at the Seoul Biennale of Architecture and Urbanism (2017), and the Hyberbody Group at the Delft University of Technology's projects Musclebody and Muscle Towers (2006), there is a commonality of exploring ways to reconfigure space based on the user needs and/or interaction. In fact, Michael Fox, author of Interactive Architecture, coined the term "robotecture", which explores "human and environmental interaction and behaviors, embedded computational infrastructures, kinetic and mechanical systems and physical control mechanisms" (2009).
Elizabeth Diller, in an interview about the use of moving parts in their practice, explains, "It's not the movement that is important. It's the speed of its responsiveness to the needs of the artist" (Davidson 2016, 59). In this statement she explains the necessity of the artist to not limit ideas or the actualization of ideas. Such freedom within architecture provides a means for the discipline to evolve to the growing needs of occupants within a digital age. In an interview with Sidewalk Lab regarding the development of the Shed along the High Line in New York, Diller describes that society is moving so quickly and it is essential that the architect's work try to respond to the shifting needs of society and the need to create an architecture which is both supple and distinct (Jaffe 2019).

2. ARCHITECTURAL ROBOT PEDAGOGY

2.1. Epistemological Change

Within the context of the historical and contemporary practices involving architectural robots comes a need for a complementary idea about robot pedagogies. Beatriz Colomnia urges for experimental pedagogies in architectural education when writes, "As schools appear to increasingly favor professionalization, they seem to drown in self-imposed bureaucratic oversight, suffocating any possibility for the emergence of experimental practices and failures" (Colomnia 2012). By looking back to the educational experiments of the 60's and 70's, she reminds us of the epistemological changes resulting from pedagogical practices that support a willingness to walk into the unknown. This kind of epistemological change, which forces designers to challenge, question, and rethink, is most important consequence of the subsequently outlined *Robot Project*, at least for now.

2.2. Methodology

Instead of amplifying anxieties about conditions of alienation produced by advanced technologies and machines, the *Robot Project* draws on the history of humanistic concerns seen in the architectural robot legacy and looks for ways that living with and within

the machine permits discovery of newfound intimacies between ourselves, each other, and the world around us. The *Robot Project* was part of a course, of approximately seventy architecture students, that aims to rethink current pedagogies for computational design. It imagines a space of learning that integrates craft and speculation, criticality and creativity, and innovation and social consciousness through production of architectural robots.

Drawing on the definition of a robot, which involves complexity of motion and programmability, paired with the essential qualities of architecture (i.e., space, occupation, light, experience, etc) the project asks students to combine these two characteristics in order to both design and build a working prototype of an architectural robot. Due to the scale and nature of the class (i.e., large scale and conducted outside of the studio setting), the project encouraged self-guided intellectual play through prototyping and workshops in physical computing. For instance, the first workshop was a two hour long design charrette in which the students, working in groups of two, were given a small DC motor and wired battery pack and told to make an object that propels itself forward with materials that are found, recycled, reappropriated, etc. Additional workshops topics included introduction to programming, the basics of physical computing, actuators, sensing, and mechanisms. The project methodology focused on hands on making and prototyping in parallel with modeling in order to see problems related to geometry, materiality, and fabrication. The students also explored historical and contemporary examples of architectural robots to help inform and promote discussion around their own creative narratives.

One of the resulting designs revisited Archigram's Walking City project through the lens of Theo Jasen's Strandbeast using a linkage configuration to both support and accentuate the performative nature of their robot's walking motion (Figure 1). Other student groups envisioned designs for the autonomous cars which separately housed a movie theater, gym, and library in order to provide programmatic amenities during the commute (Figure 2 and 3). Another group sought to explore the use of real time news data to filter out key terms related to gun

Source: (Rachel Dickey 2019)

violence such that their robot would change shape in order visualize conflict in public space and provide a place where conflict is exposed, debated, and transformed (Figure 3). Inspired by Bauhaus pedagogies which included event, performance, and cultural play space, and in lieu of traditional formal design review, the students organized a concluding event and performance of their thirty-nine uniquely designed, fabricated, and programmed robots that strut their computational prowess while walking, rolling, even dancing down a fifty foot long catwalk in their final exam time debut. Driven by Bluetooth technology, and designed and actualized through physical computing and digital fabrication, these robots dared to excite and challenge ideas about the contemporary discourse and discipline of architecture. Evolving from the inherent interest in objects that move, the event also acted as a way to invoke curiosity about the work from faculty and students alike.

Rethinking the culture of design, making, and presentation, the students organized the arrangement of the runway space, designated a DJ to play each robot's theme music during their runway walk, and nominated a series of commentators to actively describe each robot during the runway debut. Some of the descriptions, prepared by each group, read like a detailed high fashion garment summary, while others read like a World Wrestling Federation commencing narrative. Both the project and related event draw a finer line between rigor and play. Similar to the motivations of the Bauhaus, as described by teacher, Johannes Itten when he writes, "Play becomes celebration; celebration becomes work; work becomes play" (Loewenberg 2012, 22). Like Itten's desciption the *Robot Project* and corresponding event try to encourage a design culture of fostering both critical thinking and creativity and provide a play space for responding to a world embedded with technology.

2.3. Takeaways

While a primary objective for the *Robot Project* was to introduce students to computational thinking and adaptive architecture, other architectural problems arose during the project. Students had to consider how to integrate mechanical systems by including their micro-controller, network of motors, gears, power supply, etc. Many for the first time, were exposed to working with integrated systems and specifications in order to understand the basic information related to their actuators, such as ratings, voltages, torque, etc. Additionally the students directly engaged in fabrication problems through both physical and digital prototyping, in which they had to consider material tolerances and material properties such as bending radi, elasticity, and even the coefficient of friction in order to get enough resistance for movement. Thus, the project constraints stemmed from the design problem of making an operational robot relative to their larger narratives regarding transformation of space.

As growing emphasis on information and integrated technologies in the built environment place a new set of requirements on architects, the students were also provided with the opportunity to explore alternatives to previously determined conditions and embrace both quantitative and qualitative characteristics of dynamic systems. The explicit goals for the project seek to explore the boundary between robotics and architecture and promote creativity at their intersection by encouraging novelty with intention. It also strives to introduce students to critical ways of thinking about technological integration in architecture. While the project operated under these objectives, the course also took on a transformation from its traditional pedagogy which shifted focus from the application of computation in design for the generation of new formal languages to the appropriation of

computation as a means for thinking about integrating feedback in architecture.

The difference in shifting focus on computation as formal language to a means of understanding feedback relates to what Theo Spuyroploous, calls "the shift in preoccupation from building as object to building as system" (2011, 425). Early digital architects found interest in this notion of feedback not only related to production of design, but also integrated into the performance of architecture. For instance, Kas Oosterhuis explored shape changing structures using real time content to accommodate changing use over time in the Trans-Ports Multimodal Pavilion (2000). The nodes of the pavilion would change position to allow the overall surface to shift in form. Oosterhuis describes early revelations regarding an adaptable and shifting architecture when they were fabricating the Waterpavilion (1997) with NOX:

> We realized that CNC production machines do not read drawings but process data instead. So we decided to produce data which were directly used by the algorithms running the machines. It was the birth of deep parametric design to production. [….] This triggered me to think of architecture as a dynamic system, not only in the design phase where everything is still moldable, but also in its behavior as a built structure. (Oosterhuis 2017)

Through the lens of the parametric model, Oosterhuis suggested a mindset in which parametric animation does not stop, instead architecture itself could be set of parameters in motion guided by feedback. In other words there was an interest in not limiting architecture to "a static representation of a dynamic process" (Perry 2012, 73), but instead allowing the process to inform a flexible architecture. Thus early digital architects caught up in formal possibilities, like the modernist interest in the machine relative to stylistic concerns, lost sight of its origins, which Oosterhuis explains showed interest in the integration of contingency in architecture. Another important lesson from the class was the consideration of time and speed relative to the built environment. Most students chose to think of architectural robots purely as a means for producing dynamic buildings and spaces and few considered how their robots situated in space change human behavior and activate space differently which is also inherently architectural. Overall the course placed emphasis on design ideas actualized through prototyping rather than efficiency or optimization. Future development of the project and course could include interdisciplinary collaboration between engineers and architects in order to advance kinematic components, while also exploring ways to enhance, define, and accommodate spatial needs. The hope of the *Robot Project* is to generate a new generation of architects that are able to realize architecture as a system, but also equipped in conceiving of novel spaces, environments, and experiences.

CONCLUSION

> Skeptics may well wonder: Why complicate our buildings with robotics? We'd be the first to agree, for example, that buildings should employ windows, not air conditioning and artificial lighting, to make the most of daylight and natural heating and cooling. Still, who would deny that electric lighting and central heating extend the usability of our buildings? We see architectural robotics the same way, as potentially extending and enhancing the use and usability of our built environments. (Gross 2012, 32)

The rapid changes brought on by an information based society and the complexity that exists within negotiating systems and forms relative to varying needs of the occupant have generated a desire for

dynamism and indeterminacy which greatly contrasts with the traditional architectural ideals of determinacy and permanency (Bhatia 2012, 216). The architectural robot legacy and project outlined looks outside the "static status quo" and instead envisions the integration of computation in design as a means for examining feedback directly related to human factors, which could evolve to include flexibility of use and unique forms of experience.

While automation of robots in the built environment is already being discussed by engineers and specialist in human computer interaction, current trends sum up an automated architecture to no more than a "disembodied voice" with voice control systems or "a world of scaffolds and screens" (Kilian 2018, 233; Young 2016, 130). Conversely if we revisit Corbusier's expression and really explore what is might be like to live with or within the machine, opportunities arise for novel spaces and structures that address human needs and ways living, perhaps even needs we never even knew we had or ways of living we have yet to explore. If we, as architects want to be leaders in the discourse and practice of determining the advancement of the built world, then we must carefully reconsider the machine for living and imagine a new set of possibilities for exploring the integration of feedback and responsivity into the built world.

PAPER #5.04

THE CUTTING (ROUNDED) EDGE OF 3D-PRINTED ARCHITECTURE

Rodrigo García-Alvarado[a], Alejandro Martínez-Rocamora[b], Francisco Quitral-Zapata[c]
[a]Universidad del Bío-Bío, Concepción, Chile
[b]Universidad de Sevilla, Sevilla, Spain
[c] Universidad Federico Santa-María, Valparaíso, Chile

ABSTRACT

Digitally controlled machines and rapid solidification mixtures are allowing to execute buildings through 3D-printed construction with a reduction of resources, waste, time and manpower. Moreover, this technology provides a direct flow from design to execution. However, the general characteristics of buildings made with this technology have not been confirmed yet. This work aims to identify features of architectural design with 3D-printed construction through material tests, study of cases and digital models, with the purpose of guiding the building development. Printing proofs show the execution of elements with rough textures, rounded corners and limited ranges. The cases analyzed demonstrate the emergence of a variety of buildings executed with different equipment which share some construction conditions. Digital modeling of 3D-printed buildings offers opportunities of analysis and optimization, especially regarding curved walls, as well as the integration of fabrication design and control. The sinuosity of printed walls becomes a preview of the innovative spatial features that this technology is able to provide. This review reveals novel operational and perceptual conditions of 3D-printed architecture that indicate possible evolution in the roles of design and buildings in the city.

KEYWORDS

3D-printed construction; curved walls; additive manufacturing; architectural design; parametric programming.

INTRODUCTION

Digital control of machines and the fast hardening capacity of certain materials has promoted the emergence of new 3D-printing technologies. These technologies have allowed executing individual constructive elements or entire buildings (Labonnote et al. 2016; Delgado Camacho et al. 2018) that can reduce consumption of resources, waste, time and manpower in the construction industry, while providing higher accuracy and digital integration between design and execution. This leads to examine what would be the appropriate characteristics of buildings made with this technology. Therefore, this work aims to identify specific features of 3D-printed architectural design through the study of material tests, cases executed and digital models in order to boost the development and experimentation with this new technology.

3D-printed construction is an additive manufacturing (AM) process based on the deposition of a fast-solidifying fluid material that allows executing human-scaled elements (Craveiro et al. 2019). This deposition consists in the extrusion of a mixture pumped to reach a nozzle that is vertically attached whether to a 3 DoF gantry system or to a 6 DoF robotic arm. In some

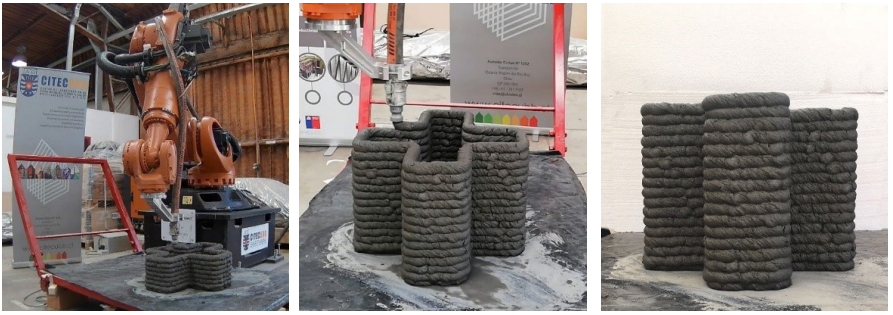

Figure 1. Printed construction experiments with a Kuka120 R2500 robot. Source (Authors 2020).

occasions, there is an additional control, feed or pushing device in the final section of this system. The material pumping must synchronize with the movement speed of the nozzle, which is controlled by the gantry system or the robotic arm through digital programming of the deposition trajectory. This trajectory is determined from a geometrical model and usually divided in horizontal paths that define successive layers of material extrusion.

At the Universidad del Bío-Bío (Concepción, Chile) initial printing proofs were first performed with a small experimental gantry system (1 x 0.6 x 1.2 m) and a mobile deposit of 9 liters. Nowadays, more advanced experiments are being carried out using a Kuka120 R2500 robot with an action radio of 2.5 m, along with a concrete pump of 120 liters to build wall sections, columns and free-form pieces (Fig. 1). These proofs have made it possible to test cementitious mixture, to define procedure for printing proofs, and to identify construction features that have been found to be coherent with other experiences worldwide (Bos et al. 2016; Ghaffar, Corker, and Fan 2018; Ma, Wang, and Ju 2018).

1. THE CORNER ISSUE AND OTHER PECULIARITIES OF 3D-PRINTED CONSTRUCTION

When using 3D printers with fused deposition modeling (FDM), extrusion feed rates are proportional to the lengths of linear segments usually employed. However, in Computational Numeric Control (CNC) machines velocities does not remain constant during the path defined. At the beginning of each segment, the devices must accelerate until a constant speed is reached, and then must decelerate when approaching a change of direction. As a result, an excess of material is deposited in those zones where the trajectory's geometry abruptly changes (Ertay, Yuen, and Altintas 2018). This issue is also known as 'overshot corners'. Through a correct calibration of the speed, acceleration and over-acceleration (jerk) parameters of each axis, the flow rate or extrusion multiplier, and other parameters that can be configured through software, clean edges can be achieved, but there are also machine vibration.

In 3D-printed construction, the Contour Crafting (CC) method incorporates 4 DoF (TX, TY, TZ and RZ), where controlling the rotation of the nozzle during the printing process, to keep a tangential direction. However, in certain moments, the nozzle must stop or slow down the extrusion while

rotates and pushes the material from the opposite edge and this technique tends to create bulges around the corners. Therefore, the nozzle must reduce the flow rate when approaching a corner, and that reduction depends on the corner's angle (Khoshnevis et al. 2006). In rectangular extrusion nozzles another known effect is the torsion of mortar cords in corners. To avoid this torsion, the nozzle's direction must remain tangent to the deposition trajectory in synchrony with the tangential speed and the material pumping pressure. These parameters are directly related to the viscosity of the cementitious mixture (Bos et al. 2016).

Other effects are attributable to the electromechanical configuration of 3D printers or 4 DoF machines. Acceleration and deceleration ramps are necessary to break the inertia of the motors that are part of the pumping and/or extrusion devices. These configurations do not allow printing right angles because of the deceleration of the printer before reaching the corner. This results in an enlargement of material in the outer part of the arc (gap) and an over-accumulation in the inner arc of the corner (Fig. 2). Therefore, it becomes necessary to use a curvature radio in the edges to achieve an homogenous deposition of material (Borg Costanzi et al. 2018). Similar than fillet procedure in digital drawing of corners to execute regular trajectories.

Another printing issue is the cumulative angular error in corners of CC systems with 4 DoF. The nozzle must reach the required rotation in the last segment of a line when it passes through a corner. When the nozzle's rotation speed is too low to finish the rotation within that segment, an angular error arises that the system tries to correct in the next corner. These errors accumulate layer after layer, especially in short segments with great curvature radios (Xu et al. 2019). More effects, such as the lack of material at the beginning of a deposition trajectory occur because of the delay between the start of material pumping, the material's inertia in the interior of the hose, and the deposition movement. The effect of this discoordination increases in trajectories starting and ending in an orthogonal vertex, where they produce whether an excess or a lack of material (i.e. bulge or gap).

A different approach to this 'corner issue' in 3D-printed construction is presented in the CONPrint3D® (Krause et al. 2018; Mechtcherine et al. 2019), which consists in the use of a nozzle especially designed to end straight trajectories with no direction changes, combined with the overlap of cords with a rectangular section. This approach implies a discrete cut (true-false) of the monolithic cords in an alternate way avoiding continuous control of the extrusion flow rate. When approaching a corner, the pumping is abruptly stopped, then the rotation and new

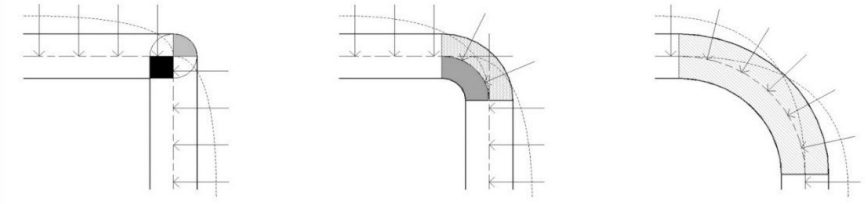

Figure 2. Material deposition in corners with different curvature radios. Source (Authors 2020).

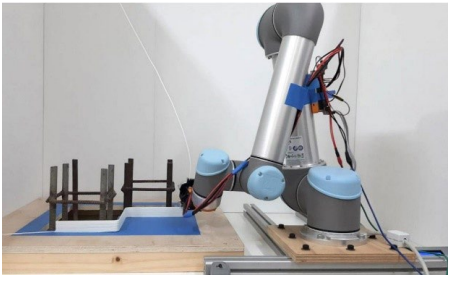
positioning is performed, and the pumping is started again to continue with the next straight segment. Thus, the overlap and gap effects in corners that arise from continuous rotation (RZ) in conventional CC systems with 4 DoF are avoided.

The use of robots with 6 DoF in 3D-printed construction can avoid the continuous flow rate and material pressure control in pumping equipment. The robot-based continuous welding technologies used in automotive industry allow the robot's end-effector to describe trajectories with continuous speed. This process only requires coordinating the start and stop via programming code. The use of conventional slicing programs for FDM that are usually applied in 3D-printed construction experiments to generate straight segments in G-code can be replaced with parametric control tools such asHAL or KUKA|prc , which already integrate continuous trajectories, lines, continuous arcs and splines.

Aside from the 'corner issue' here described, there are several phenomena that occur during the printing process. Since the printing material is deposited as a horizontal cord through the nozzle (which is usually circular), both a transversal expansion and a vertical reduction are produced because of the setting process and its own cumulative weight of material. As a consequence, an adjustment between the design dimensions, nozzle measurements and magnitudes of the deposited cord must be made, as well as a reduction in the horizontal joints between cords is produced making a rough texture in the elements' faces. The cord's dimensions depend on the nozzle's size, mixture density, air humidity, flow rate, print speed, opening time, and initial setting time. These dimensions must be supervised in the execution to estimate the modifications in the design to be printed and the trajectory that allow adapting to these phenomena.

When the printing path completes each lap, it is necessary to change the position of the nozzle in height, and this 'jump' produces a bulge similar to that of the aforementioned 'corner issue'. Thus, it becomes advisable to generate printing paths that follow a spiral form to avoid bulging when completing each lap. These spirals must grow the height of one cord in each lap minus the height adjustments due to the setting and cumulative weight effects. The early setting time of the mixture must be regulated to resist the weight of the subsequent layers without major dimensional alterations. The spiral trajectory, equipment range and material feeding establish maximum magnitudes for the printed elements to keep that slope progression. Therefore, sections and sequences of execution must be established according to the machines position and material load capacity.

The vertical sequence of cords is prone to overturn, especially in straight sections of



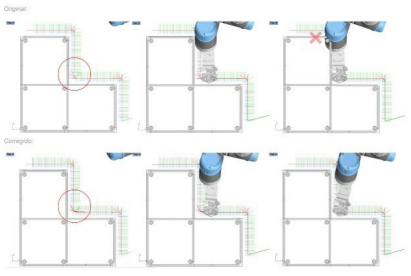


Figure 3. Perimeter printing proofs of a reinforced structural element. Source (Authors 2020).

the element, thereby making it advisable to use ample curves or transversal sections in the design. Interior reticulates also collaborate in supporting the element once executed and act as partial fillings. Additional proofs have been performed with an UR5 robot to print constructive elements with inner reinforcing steel bars (Fig. 3) aiming to determine strategies to move the robotic arm along the perimeter without interfering with them. However, this requires to apply the extruded mixture with an angle of the nozzle that allows avoiding clashes between the tool and the printed element, which can be predicted in the path programming using HAL, KUKA|prc or similar software. Also, this inclination of the nozzle generates greater accelerations both in concave and convex corners. These difficulties make also is preferable to design elements with rounded or curved edges.

2. ARCHITECTURAL EXAMPLES OF 3D-PRINTED CONSTRUCTION

The aforementioned preference of curved shapes has been also present in several examples of 3D-printed buildings worldwide (Perkins and Skitmore 2015; Hager, Golonka, and Putanowicz 2016; Tay et al. 2017). By September 2019, the authors identified 68 experiences in different countries, through a review of websites and scientific papers. These experiences were made by enterprises, universities and/or national programs, and mostly destined to experiment with this new technology and to present examples of what it has to offer. From a small refuge in Milano in 2010, a hotel in Philippines and an office in Dubai in 2016, a house in Russia in 2017, an emergency dwelling in Texas, an energy efficient house in Nantes and another one in Valencia in 2018, 3D-printed construction is spreading at a fast pace. In Latin America seven initiatives have been registered: a dwellings prefabrication company and three universities in Chile, and diverse enterprises in Colombia, Brazil and Argentina.

Most of these initiatives have appeared in the last four years, combining printed elements with other conventional components. 66% of them were executed with gantry systems and 18% with robots, and the vast majority with cementitious mixtures. The WinSun company in China exposed up this date fifteen buildings made with 3D-printed construction, some of them with several storeys, dwelling groups, or urban furniture, but without details on the components and processes used. Cybe (Netherlands), ApisCor (Russia), Printhuset (Denmark), and the Engineering Corps of the US Army presented printed buildings, and even designs, equipment and mixtures to sale. Besides, several institutions have participated in NASA competitions focused on extra-terrestrial construction.

The buildings presented are generally little houses or pavilions around 50 m2, with one floor and some common characteristics such as use of 3d-printed construction mostly in walls with rounded corners and ample curves. These designs use whether filled single-cord or hollow envelope with parallel cords. The visible texture is covered in some cases, and complemented with decorative vegetation, doors, windows and installations. Windows and doors are usually scarce and narrow, and roofs use a different constructive system, whether in wood, metal or concrete slabs. Speed and low cost are frequently highlighted as the main advantages, as well as waste reduction, higher safety and design versatility.

In the latest months, a big building printed in Dubai by ApisCor has been presented, using straight and circular walls. Also, the NASA contest for extra-terrestrial construction showed proposals based on vertical shapes with conical roofs and scarce openings (Fig. 4). Besides, a sinuous design for a dwelling has been executed in Morocco by the Spanish company BeMore3D in the Solar Decathlon Africa contest, as well as a second pavilion

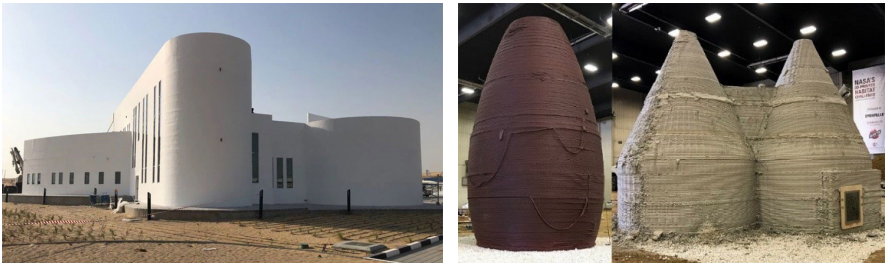

Figure 4. Examples of 3D-printed construction; office building in Dubai (left); constructions in NASA contest (right). Sources: (https://www.apis-cor.com/, https://spectrum.ieee.org/tech-talk/aerospace/space-flight/3d-printers-could-build-future-homes-on-mars, photographer Tracy Staedter)

by the US Army. The companies COBOD and Cybe are executing buildings in different cities of Europe and Asia, and developing equipment and commercial organizations. In their constructions, modular walls with inner reinforcements and services have been observed.

3. BIM MODELING OF 3D-PRINTED ARCHITECTURE

The control of 3D-printed construction requires digital modeling, then some studies have devoted on testing BIM for design and planning printed buildings (Lim et al. 2016; Davtalab, Kazemian, and Khoshnevis 2018). The digital management allows also to analysis constructive conditions like shape optimization. For example, curved partitions provides greater stability against lateral forces than straight (Kounadis and Papadopoulos 2016; Lagomarsino 2015; Liu et al. 2018). Like 3D-printed construction can execute any shape, and in particular curved envelopes, this attribute can reduce material consumption, as well as to decrease environmental impact, manpower needs, waste and transport.

A geometrical analysis was developed by the authors through parametric programming in BIM for the configuration of a 40x20m rectangular enclosure by generating 1,600 randomized alternative solutions of straight and curved walls (Martinez-Rocamora et al, 2020). Considering similar overturning limit force for a straight wall 30cm-thick, and different curved walls with the same projected length but lower thickness depending on the curvature angle. However, it is worth noticing that using curved walls modifies the built-up surface of the enclosure, reducing it with an inner arc and increasing with an outer arc, besides increasing the effective length. In contrast, highly reduced thicknesses are not buildable and do not provide the required noise and thermal insulation. Thus, several factors must be compensated by combining several wall types in a same enclosure or building. Based on the estimation of volume, time and cost as resources for the execution of each solution, it was possible to evaluate their cost-efficiency. The programming allows identifying the most efficient designs to reduce the options that the architect should evaluate from an aesthetic viewpoint according to the spatial and formal expressiveness (Fig. 5). In the shown example, the design with the lowest time of construction presents more pronounced curvatures, while the solution with lowest consumption of material shows soft curves in all its sides. The combined analysis throws a solution with strong curvatures in the extreme sides and soft curves in its long sides. Thus, the architectural solution can

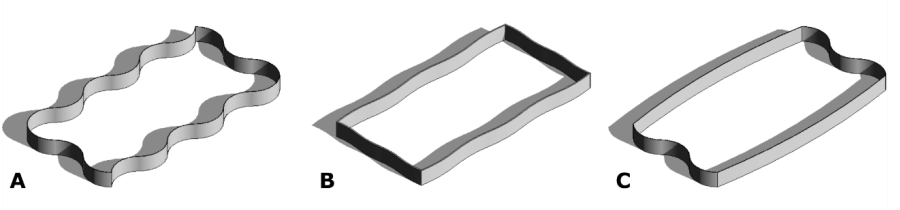

Figure 5. Renders of the best solutions in BIM analysis of envelope with 3D-printed walls in terms of material consumption (A), execution time (B), and economic cost (C). Source (Authors 2020).

consider whether an operational efficiency or economic reduction, with a more functional or expressive design, according to the activity or the building location.

Another initiative derived from the study of 3d-printed curved walls was a practical exercise in BIM with architecture, civil engineering and building engineering students. It was an intensive and collaborative work of integrated design where the students develop a project for an automotive exhibition hall in a site next to a main road with 3d-printed curved walls (Fig. 6, left). This work included building design, budget and energy consumption estimations, as well as architectural visualization, structural and construction details (García-Alvarado et al, 2020). The project was developed during two meetings and four collaborative work sessions of three hours each. Despite some differences among the participants occurred during collective work, it was possible to complete the design with the proper documentation and relevant architectural proposal consistent with 3D printing of curved walls.

In addition, experimentation with definition of 3D printing elements like families in BIM has been carried out. These elements were parameterized according to the analysis conditions, and exporting code for 3D printing through KUKA|prc in Dynamo (Fig.

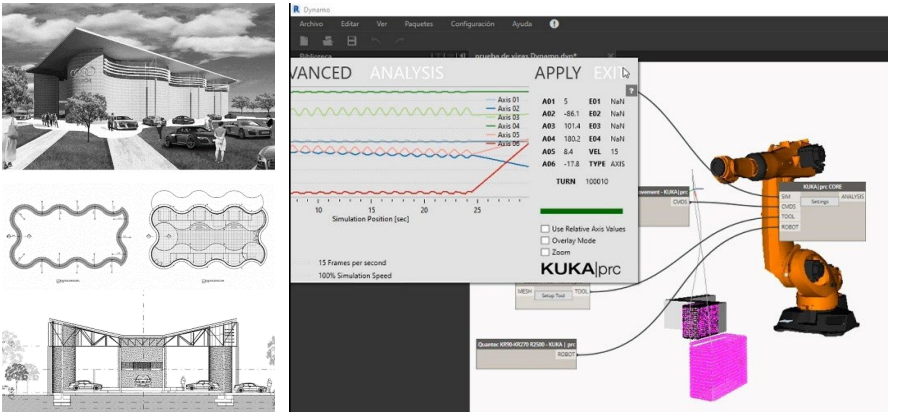

Figure 6. Excerpts of Design Exercise (left), 3D-printing programming in BIM (right). Source (Authors 2020).

6, right). In this case, families were defined for the repertoire of curved walls with angle and thickness variations, as well as material consumption. Also execution toolpaths were defined according to the equipment and concrete pump ranges, thus allowing to program printing trajectories for 80x40x20cm elements. These trajectories follow a helical tour adapted to the estimated dimensions for the printing cord, its vertical setting, and lateral displacement. The programming is usually generated from the volume section of the element by controlling the parameters of the trajectory according to the total length, corners' radio and the available volume of material, and subsequently the G-code for the robot is exported by KUKA|prc. With the robotic arm's control panel, the position of the element, direction of the trajectory, height adjustments and stops of the printing process are calibrated.

These experiences demonstrate the potential that BIM modeling offers for managing an architectural project based on 3D-printed construction, regarding the study and development of technological features with greater effectiveness. It also shows the singular expressiveness of 3D-printed architecture through the use of sinuous forms to accommodate interior spaces and innovative exterior appearance.

4. DISCUSSION

Printing constructive elements requires planning and executing a trajectory of deposition considering the machine capacity, range and constraints in corners. This technique produces rounded edges and textured surfaces. Besides, the building procedure promote curved walls, which can be optimized, integrated and controlled through digital modeling and fabrication. Thus, the design of 3D-printed buildings requires establishing sizes of rooms according to the central measurements of the spaces (see Fig. 7, left) and subsequently determine detailed tool-paths for walls and corners, which must be preferably rounded. Therefore, architectural work must establish the occupation and magnitude of spaces within an integrated analysis and management of construction process, apart from to establish the envelope according the equipment available and deposition strategy, with convex edges that could difficult the fitting of furniture but promote the interiority of activities and a fluid perception of surfaces.

The horizontal and sinuous configuration of 3D-printed buildings also provides a combined appearance of technological innovation and ancestral stability (Fig. 7, right), with curve walls and rounded corners that dilute the visual awareness of edges,

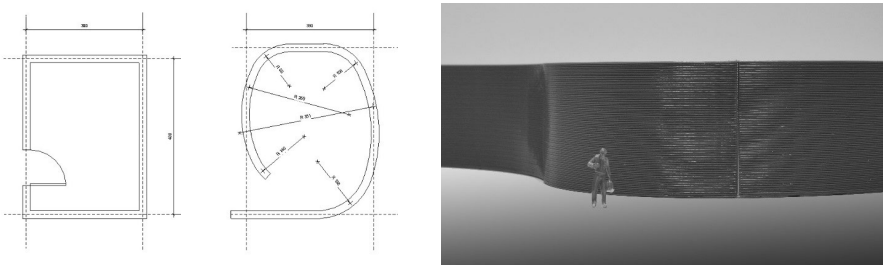

Figure 7. Drawing of conventional and 3D-printed buildings (left) and 3d-printed models (right). Source (Authors 2020).

thus privileging the expression of settled and continuous volumes. The perceptual extension of the faces prolongs the contours and dissolves limits, linking adjacent spaces and activities. Combined with technological and cultural meanings, architecture associated to 3D-printed construction promotes new social relationships, and the design are pushed to functional organization that must articulate technical procedures and expressive capacities of buildings and their urban possibilities.

CONCLUSION

The various proofs, designs and examples built with 3d-printed construction to date present novel architectural features. Material deposition produces rough textures in the building elements, with rounded corners and limited sections. Digital modeling allows integrating and optimizing construction, especially with varied and curved shapes. Buildings executed mostly have 3d-printed long and winding walls combined with conventional roofing elements, windows, installations and coverings. These conditions express an incipient architectural development oriented to an integrated management of design and execution focused on operational control and functional organization. But also, sinuous forms in buildings allow dedicating inner spaces to diverse activities and new expressions. Hence, this work provides a novel and initial review of architectural design with 3d-printed construction that suggests an emerging landscape of the architectural work and the cities' built tissue.

PAPER #5.05

THE CITY AFTER THE CATASTROPHE. DILIGENT STRUCTURES

Raquel Martínez Cuenca[a], Ricardo Perelló Roso[a]
[a] Universitat Politècnica de València, Valencia, Spain

ABSTRACT

In the last twenty years, society has witnessed complex humanitarian emergencies caused by radical atmospheric phenomena or sudden political changes with warlike consequences that have produced exceptional movements and resettlement of affected citizens. These emerging circumstances have hit especially hard the most disadvantaged sectors of the population. Needs for land preparation and fast small and large scale housing construction have emerged in order to accommodate those affected in the short or medium term.
In adverse environments, these needs require the generation of diligent architectural structures. In order to fulfill their objectives, these agile and versatile skeletons must be executed at local level, involving the citizenry and using as much autochtonous materials as posible. Capacities ans skills of the locals must be focused on four fundamental concepts: self-construction, portability, sustainability and reuse.
This study traces an introduction to the state of play regarding these diligent architectural studies. It exposes the problem of creating a model which responds by means of folding structures or dismountable ones, to the needs of each emergeny situation. Qualities such as versatility, adaptability to the problem, basic functionalities and conditioning factors are analyzed.

KEYWORDS

Deployable structures; removable structures; sustainability; self-construction; reuse.

INTRODUCTION

Since the 1990s there has been a growing interest not only in providing rapid accommodation for people who lose or have to leave their homes for a variety of reasons. But there is also an interest in making these habitats as safe, useful, flexible, reusable and sustainable as possible. Each location and each town has a certain and very specific idiosyncrasy which makes it unique. The shelter models implemented must be capable of responding to these needs with structural systems that are flexible enough to be able to adapt to different lifestyles, multiple locations and climatic conditions, with the use of sustainable and reusable materials. The present study aims to establish an approach to the needs that each emergency situation requires, the most appropriate type of accommodation in each case and which models of structure can offer a better response, without forgetting the needs of the individual and the sustainability of the system, i.e. its life cycle.

1. SUSTAINABILITY OF COLOR

After the Second World War, due to advances in technology, improved infrastructure and new communication systems at a global level, a movement of aid and collaboration among countries in case of humanitarian disasters and war began to be generated. After the Rwandan genocide in 1994, one of the largest population migrations of that decade took place and ths Sphere Project emerged. During that conflict, significant coordination failures among the different humanitarian

organizations that went to the area to help were observed and the success of those missions was meaningfully reduced. The aforementioned project was launched in 1997 with the aim of improving coordination among humanitarian organizations and of establishing common operating protocols for them all. The goal of the Sphere Project is to establish common principles and minimum quality standards in the event of having to act in any type of humanitarian emergency. These minimum standards are reflected in its "Humanitarian Charter and Minimum Standards in Humanitarian Response", which is regularly updated and revised. As the fundamental philosophy of the project, we can read in its Humanitarian Charter "[...] the right to live with dignity: the right to receive humanitarian aid and the right to protection and security." These rights are complemented by minimum standards covering the needs for: water, sanitation and hygiene promotion; food security and nutrition; shelter, settlements and non-food items; and health services. The present work will focus on this need for shelter and settlement. Two of the main causes behind the need of generating new housing are natural disasters and warlike conflicts, and both cases have different origins and needs that condition the type of response. Aspects such as the volume of population to be rehoused, the urgency with which the accommodation is needed, the assembly times, the duration of the stay, the model of population to be housed (family or individual nuclei), the lifestyle in the area (more or less rural), the climatic conditions of the area and the natural resources of the area determine the shelter model. Broadly speaking, we can establish two strategies that will condition the model of refuge to be implemented as a response to this need for new accommodation. The first one would consist of trying to maintain and respect the existing housing model by readapting it, reconstructing it and improving it and the second one would consist of standardized models or exported from other areas (Davis, 1978). Another important aspect to take into account when considering an efficient shelter design is the time factor. Up to 6 months we talk about emergency aid or what we could call immediate survival; after that time we find ourselves with humanitarian aid or post-disaster rehabilitation; and if the situation lasts for years we are facing a humanitarian action that would imply the reconstruction of the area (Ros García 2015). Any analysis of these issues shows that immediate relief, rehabilitation and reconstruction, although they are distinct phases, constantly interfere with each other, and immediate decisions taken a few days after the disaster usually influence long-term events (Davis, 1978).

2. METHODOLOGY

The bibliographical references shown in part 6 have been used for the drafting of this article, as well as consultations on specialized websites and search engines. Internet searches have been used mainly to extend and update the information on those interesting projects described in the books and whose description was too short, but interesting to extend in order to be able to go deeper into the subject.

3. DISCUSSION

In order to draw conclusions about the best shelters for each context, it is necessary to know which emergency accommodation solutions can be considered. The goal of the current work is, firstly, to analyse as many different models as possible from different points of view, namely: type of assembly, compactness of the system, reuse possibilities and structural system; and, secondly, to establish a classification of the different models employed in order to analyuse pros and cons, establishing then the suitability of each system

in each situation. For this reason, models implemented since the 1970s to the present have been studied, both used in the field and in the prototype phase or still under study. After the analysis a classification according to the constructive and structural features of the shelter models studied will be established.

3.1. Compact units

Compact units are already manufactured products, completely autonomous which do need no or very little assembly. They do not respond to any specific structural system. These models of refuge usually respond to rigid configurations that clash with the forms of traditional architecture of the place and use materials not always available in the area. Hence, it is a kind of model that has some acceptance as immediate accommodation but little success as a habitat in the medium or long term.

Dymaxion deployment unit

The Dymaxion Deployment Unit (DDU), or Dymaxion House, was created by Buckminster Fuller in 1940 to house American soldiers deployed around the world during World War II. It is a circular structure of about 6 m in diameter made of corrugated steel that resembles a silo. The dome shaped roof has perforations acting as windows and an upper ventilation hole. The interior is insulated and finished with wooden panels (fig. 1). This structural model was the germ of the "modern igloos", minimal constructions intended for housing and, later, of the geodesic dome (1948). The "modern igloos" were domes with an octagonal structural matrix that provided stability to the whole using a minimum amount of material. However, they were barely accepted as a shelter due to the rigidity of their shape.

Figure 1. Dymaxion deployment unit. Library of Congress: U.S. Farm Security Administration (Daderot 2011)

Western Germany Red Cross polyurethane igloo

Polyurethane igloos were used by the Western Germany Red Cross in 1972 as shelters after the Masaya earthquake in Nicaragua. It could be assembled in two hours, but it took more than 148 hours to occupy the first one as the right location could not be found. Of the 500 units assembled, only 30% were finally occupied because the model did not meet the living needs of the population.

CMAX System

The CMAX System is a prototype designed by Nicolás García Mayor in 2001 (fig. 2) which, according to the official website, consists of a housing module with a rigid central structure, built in polypropylene, aluminium and polyester fabric; and two wings made with a flexible material that, when unfolded, quadruple their size. This kind of shelter can

Figure 2. Cmax System housing shelter (García Mayor 2013)

withstand strong winds, is waterproof and easy to transport, as it is light and foldable and can be raised above the ground on a set of legs. It can host up to ten peoplele. With the adequate tools it can be assembled and secured in about eleven minutes.

3.2. Deployable structures

Deployable structures usually involve some mechanization and the use of their own materials. These structures are quick to assemble since joints are scare because the whole model is frequently solvid with membranes, curved sheets, domes or vaults. Models based on deployable structures display many possibilities for configuring the space beneath and around them. They are easy to be transported because of their reduced weight. They can be expanded or contracted because of their geometric, material and mechanical properties, turning them into meaningfully changeable elements with the possibility of constantly evolving and adapting to the architecture of the area where they are implemented (Rivas, 2015).

UNHCR Lightweight emergency tent

Tents are the most widely used system when it comes to generating new emergency accommodation. That fact responds to their economy, speed of assembly and versatility. On the contrary, these models do not always respond correctly to the climatic conditions of the area and have a very limited durability without the possibility of reuse after their lifespan. The most basic model consists of a double-flight tent with a central support and side braces that provide rigidity to the canvas. There are multiple variations and extensions of this model which even considers a model resolved with a dome. As a remarkable example, the UNHCR model was initially used in 2002 and is still in service.

Concrete Canvas Shelter

Commonly known with their acronym CCS, Concrete Canvas Shelters are constructed with CC13 concrete canvas, bonded to the outer surface of a plastic interior. The first step of the building process consists of inflating it. Once it has reached its final size and shape, it is hydrated with water and after twenty-four hours, it becomes a rigid structure ready for use. This typology generates curved structures of thin concrete wals which are both robust and lightweight. Concrete canvas shelter units can be coupled and arranged in series to generate sets of structures. The first prototype was developed in 2003 and is currently a registered system.

Weaving home

This prototype designed in 2013 by the architect Abeer Seikaly, re-examines the traditional architectural concept of field shelters by creating a technical, structural fabric which expands to protect but also contracts for later mobility while providing the comforts of contemporary living such as heat, running water, electricity, storage and many other.

3.3. Detachable structures

Detachable structures encompass all those structures which must be mounted entirely on site and require a much longer and demanding process to be finally assembled. In turn, this system has greater versatility making possible the use of local materials. Detachable structures display a much larger variety of structural models which range from framed systems with gabled or curved roofs to systems based on vaults or domes. The main purpose of a detachable structure is to be able to achieve more and better results with the smallest amount of resources as possible. This cathegory also aims to adapt the system proposed to provide answers to the specific needs of the area to be

intervened considering local resources and means. Therefore, detachable structures will be built with the minimum amount of what is available at a certain moments and by means of self-constructing, generating a universal system which allows new constructions to be adapted to the traditional models of existing housing (Ban, 2011).

Paper-Log-House

This currently used model was designed by Shigeru Ban in 1995. It is a temporary shelter made of cardboard tubes waterproofed by means of transparent polyurethane and filled with newspaper sheets. The plywood floor is supported by sand-loaded beer crates, while walls and roof posts are formed by the aforementioned assembled tubes, thus securing the canvas roof (fig. 3). The constructions is quickly recyclable, easy to transport and store, and quick and easy to assemble by the future occupants. Actually a unit can be built within ten hours, being fully reusable after its lifespan. It is a system which has been widely accepted and used in various emergencies, adapting it to the specific climate and materials of each area (fig. 4).

Figure 3. Paper-Log-House in Kobe

Figure 4. Paper-Log-House in Cebu

House elemental tecnopanel

This prototype designed by Chilean architect Alejandro Arevena in 2010 consists of a modular, mountable housing unit designed to meet housing needs during the floods which in that period affected his country. Its most remarkable characteristic is that, once assembled by three people in just one day, it can be both used as a permanent housing or as a temporary dwelling and then reused. It is based on an elemental prefabricated kit mostly based on structural insulated panels, SIP, which are self-supporting and made with a high-density polystyrene rigid foam core. More information on this system can be found in its official website: www.elementalchile.cl.

Superadobe sandbag shelters

Sandbag shelters are dome and vault shaped constructions which combine traditional architecture with new materials. Designed by Nader Khalili in 1995 they are still in use. Sacks filled with soil are compressed with a hand rammer and distributed following a circular pattern. A barbed wire is placed in the joints to prevent sandbags from moving and to provide stiffness to earthquakes (fig. 5). The system is completed with cement, lime or asht to add even more stability (Rivas 2015). This system was used for the fist time as a shelter in 1995 at the Baninajar Camp in Khuzestan, Iran. It was one of the results of applied research at the California Institute for Architecture and Earth Art, also know as the Cal-Earth Institute, founded by Nader Khalili in 1991.

Project VEM

This prototype was produced in 2017 by the Rebirth Inhabit Research Group of the CEU San Pablo University in Madrid, Spain. Architectural models builf after the VEM prototype can be completely dismantled. They are formed by a tubular structure in metallic allow, a light panelling on its horizontal base and a reinforced double layer textile envelope. It presents important architectural advantages when comparent to other current types of emergency housing, such as assembly easiness since it can be assembled by just two people in two hours, airborne, greater adaptability of seating and an extendable capacity system. VEM prototype versatility makes possible to adapt each unit to new locations and materials.

Figure 5. Figure 5: Superadobe sandbag shelters in Djibouti in 2012

CONCLUSION

When we are faced with a natural disaster, we are dealing with a population that is deeply rooted in the area and reluctant to leave their home no matter how destroyed it is, who prefer emergency accommodation in locations close to where they live rather than in remote camps, as all their possessions are there. In these cases, where what is lost is the home they live in, they look for a temporary shelter that can provide and allow for the lifestyle they are used to, a refuge that, if necessary, can end up becoming their permanent home. On the other hand, when we are facing migration due to war, the needs are different. People leave their homes and there is no feeling of attachment to the area. The new accommodation is seen as something temporary. The main purpose will be to return to the original home or find a new one. In these cases there is more freedom to establish the location of the shelters, it is possible to make a better forecast of the volume of people to be housed and the system does not need to be based so much on local models and allows the use of materials from the area. From this we conclude that any study on the provision of housing, shelter or new habitat should start with an analysis of what is needed in that particular community, to make housing that has a relationship to local cultural patterns and not consider it as a minor issue (Davis, 1978). Therefore, in many cases the success of the model to be used depends, not so much on the goodness of the model itself, but on an adequate tuning between the model and the concrete use it is intended for. Thus, we see that forms of housing or shelters that completely ignore the cultural customs of the occupants can become a failure. And the same goes for universal solutions if they are not used in the right context. On the other hand, providing a shelter while recognizing cultural issues and trying to use appropriate

and safe construction techniques has been more widely accepted (Davis, 1978). Analyzing different systems used as emergency accommodation in recent years we can establish a classification of them from a constructive and structural point of view and assess in which situations each model has been more appropriate. We find compact units, completely autonomous and ready to start working immediately as they do not require assembly; but with little capacity for modification and adaptation to different locations. So a priori it is a model suitable for short stays, emergency aid, and in temporary locations with no intention of becoming permanent. Secondly, we have the models of deployable structures, quick to assemble and with a greater flexibility, which allow the intervention of the users as regards their final shape and the use of materials to adapt it to their needs. Finally, we have the case of dismountable structures which need a longer execution time as they have to be assembled entirely on site, which in turn gives the system greater versatility, allowing the use of materials from the area and facilitating self-construction and reuse of the system. Deployable structures and dismountable or detachable structures, due to their versatility, are more suitable solutions for location in areas where there is a strong tradition and which are considered as long term stays, humanitarian aid or post- disaster, and which can end up becoming definitive as they are adaptable, reusable and self- constructed.

PAPER #5.06

CONSTRUCTABILITY CRITERION FOR STRUCTURAL OPTIMIZATION IN BIM AND HYBRID DIGITAL TWINS

Víctor Fernández-Mora[a], Víctor Yepes[b]
[a] Universitat Politècnica de València, Valencia, Spain
[b] ICITECH (Instituto de Ciencia y Tecnología del Hormigón), Universitat Politècnica de València, Valencia, Spain

ABSTRACT

The introduction of Lean Construction standards into the AEC Industry has changed the way that the professional approach the different problems. BIM and Hybrid Digital Twins are new high demanded technologies that improve the efficiency of the industry's procedures as they allow new and faster methodologies. Optimization algorithms are often used in combination with these techniques to improve the result at several points of the design phase, including the structural project. The optimization can be done using different criteria, like the economy, sustainability, energy consumption or constructability or a combination among them. While there exist exact formulas to quantify some of these criteria there is not a universal one to quantify the constructability. In this article, we establish the key points to create a constructability criterion for each structural project and explore its efficiency. The way to quantify the constructability depends on the structural design and element to be optimized and as there is not an exact formula to quantify the different factors that influence it have been defined and their combinations explored for a certain structural problem: optimization of a concrete beam. With this, we are able to quantify the easiness to build a certain structural project and reduce the building time and crew cost and create a way to improve the structural design. This exposed method can then be expanded to different structural elements.

KEYWORDS

BIM; digital twins; constructability; optimization algorithms.

INTRODUCTION

The Architecture, Engineering and Construction Industry (AEC Industry) has been one of the most static industries in the world and has been reluctant to changes, in the last years this tendency is starting to change. The introduction of powerful informatic tools creates a new environment where automatized tools can be developed for several tasks (Eastman et al. 2011). These tools allow the professionals to improve their productivity and quality of the project and at the same time have more control over it and are based upon management improvements. Some of the management improvements to the industry are led by the increase in the usage of Building Information Modelling (BIM) Environments (Volk, Stengel, y Schultmann 2014) and Digital Twins (Chinesta et al. 2019). Both provide great advantages for the professionals as they are able to handle a lot of parameters and work with them simultaneously. Allowing the AEC Industry to introduce the different Lean Construction (LC) precepts effectively and improve the sustainability of the project. The adoption of the two different environments is an evolution to traditional methodologies and by using them the professionals are able to reduce the risk of errors during the project, achieve

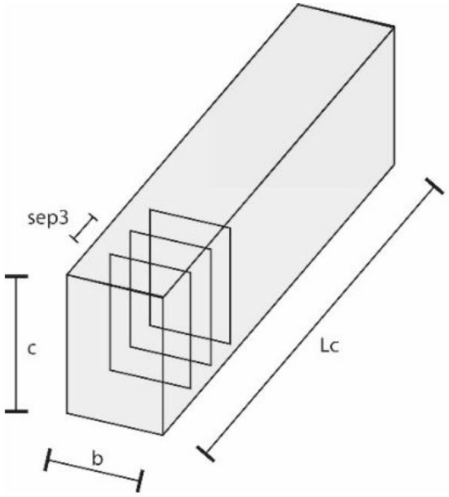
better accuracy through the design phase or their management capabilities. There is also utility when working in cloud-based servers (Jiao et al. 2013) with several people operating at the same time in the same model with coordinated modifications and improvements which are natural in both of them. There are a lot of differences among both of the previously stated environments. On one side, BIM is hard to define term as it includes three concepts: a product, the digital file where the model of the project is stored, the specific type of software and the methodology used to create the model (Eastman et al. 2011) («Frequently Asked Questions About the National BIM Standard-United States™ | National BIM Standard - United States» 2016). BIM, in reality, is a mix between the three concepts is an n-dimensional matrix of the project's data where the user can define and relate new dimensions and variables between them, this set of dimensions is the digital model of the project that is developed on a BIM software and to properly use it the methodology has to be used. On the other side, Digital Twins are one step ahead of the BIM environments in terms of project management. They do not only work during the design phase but also during the life cycle of the building. A Digital Twin is a virtual model for a certain procedure, product or service which is continuously being updated with new input from the real object on the world. For the AEC Industry, it consists of a digital model of the building itself which is being updated through sensors from the building. This model can be used to visualize, analyze, simulate and plan everything on the building (Chinesta et al. 2019). As seen each one of them has its advantages and its uses. BIM works better in the design and construction phase allowing the professionals to optimize results and procedures and Digital Twins are better managing variations and modifications through the life cycle of the building. The environments by themselves are only a framework to control the project and visualize its different aspects simultaneously. They are a completely new methodology that is starting to change the way that the AEC is working. But by themselves, they are only able to control, show and manage parameters. To fully take advantage of the environments these parameters have to be analyzed in conjunction with each other. For this purpose, the Building Performance Tools (BPS Tools) are used, as they are able to take the parameters stored in the digital environments and use them for several tasks. A lot of BPS Tools have been developed through the last ten years to improve sustainability (Chong, Lee, y Wang 2017) (Lu et al. 2017), reduce CO_2 emissions (Chen y Luo 2014), waste reduction (Akinade et al. 2015), optimize structural design (Fernández-Mora y Yepes 2017), among other purposes. A large group pf BPS Tools are focused on the design aspect of the project, helping the professionals to make decisions or even designing some elements by themselves, like structural elements. These design tools are based upon design restrictions (structural analysis and requirements) and design criteria like economy, sustainability, energy consumption or others. These design restrictions or directives can also be introduced into an optimization algorithm that is able to find an optimal design for the problem. In (Diao, Kato, y Hiyama 2011) we can find an example that uses a BPS Tool to optimize the CO_2 emissions for structural design. One of these criteria that can influence the design of a structural element and improve it is the constructability. The constructability or buildability of a certain structural element measures its aptitude to be built. So, it is a measure of the easiness to build a certain element. Lower constructability

measurements allow easier structures to be built and easier structures are more economical. It also reduces the number of mistakes occurring during the execution, because error appearance is directly related to the complexity of the element (Shrivastava, Chaurasia, y Saxena 2017). The term constructability is usually referred to several aspects at the same time. First, the extent to which the design parameters facilitate the construction of the element while achieving the building requirements. Second, the effective and time integration of construction knowledge into the conceptual planning and field operations. Third, to balance the different environmental constraints, project goals and building performance. It is not an universally measurable criteria as different factor interact in a different way for each case. In this paper, we aim to define a way to measure the constructability of an element and be able to compare it among other similar ones. This mathematical model to measure the constructability can then be used in a multicriteria optimization algorithm complementing other criteria and help the professionals to achieve an overall better design.

1. METHODOLOGY

1.1. Case Study

Per the definition above, the constructability is a criterion that has to be defined for each specific problem. So, in this problem, we will not find a universal definition to measure it, but a methodology to define it for every structural case, which will need further study. In this paper, the case study is a concrete beam with rebars on both faces and transversal reinforcement. We use a fixed span of five meters and loads according to residential use, without any particularity that may alter the design there are constraints for both, bending and movements at each ending. We assume that when measuring the constructability the design has been already validated and it is enough to resist the efforts on the beam. The constructability criteria will



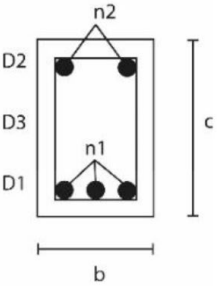


Figure 1. Geometrical parameters of a concrete beam

not check any design restriction, including those regarding the buildability itself as rebar disposition, assuming that they are sufficient for their structural requirements.

1.2. Parameter Definition

Fig. 1 contains the geometrical parameters of the beam. Its dimension is defined by two parameters, width (w) and height (h), in combination with the fixed span they define the external dimensions of the element. The distance between the face of the element and the rebar is defined by the cover (c) parameter. To define the rebar a total of six parameters have been used, three for the diameter of the different rebars: one for the diameter of the rebar in the bottom side of the beam (D1), a second for the diameter of the rebar in the top side (D2) and a third one (D3) for the transversal rebar. And three more to determine the number for each of the reinforcements: bottom rebar (n1), top rebar (n2) and the distance between the transversal rebars (sep3). Constructability is not only related to the geometrical definition of the beam, but there are also other factors that can affect it. The weight of the different materials has to be taken into account through its density with two more parameters also the relationship with the other elements in

Table of parameters	
Parameter	Measurement
Geometrical parameters	
Width (w)	Centimeters
Height (h)	Centimeters
Cover (c)	Centimeters
Bottom-side diameter (D1)	Millimeters
Top-side diameter (D2)	Milimeters
Transversal diameter (D3)	Millimeters
Number of bars in the bottom (n1)	Direct amount
Number of bars in the top (n2)	Direct amount
Spacing between transversal bars (sep3)	Centimeters

Non-geometrical parameters	
Concrete density	Kilonewton per cubic meter
Steel density	Kilonewton per cubic meter
Concrete consistency	Slump test
Rebar homogeneity	Mean value of the rebar diameter
Type of beam	h equal/greater than span thickness
Formwork	Square meters
Type of construction	On-site/Precast

Table 1. Parameters defining the case study

contact and if it is needed the formwork and its size. The consistency of the concrete is another factor directly related. On-site or precast construction can also be a key factor because the parameters interact differently between them. Or the homogeneity of the rebar reinforcement understood as the use of rebars of similar sizes. There are also factors external to the element itself such as the experience of the working crew, time of the day or weather that can affect the constructability of the element. In this paper, this is not taken into account, as our goal is to create a mathematical model able to handle the criteria for further use in the design stage. These parameters can't be known prior to the execution and are independent of design changes and they can introduce noise in the model that will not improve it as they are nor design dependants. A total of 16 parameters have been used to define the constructability of a beam. Table 1 summarizes the different parameters and the units utilized to measure them. Some parameters are not measurable and describe certain characteristics of the element. To be able to compare and combine the factors into one criterion it is necessary to unify and categorize them. For this, a survey has been conducted among several AEC professionals, including architects, engineers and constructors asking for a hierarchy among the parameters.

2. RESULTS

2.1. Parameter Definition

The survey asked different professionals to sort the parameters in order of relevance for the constructability of a beam. With this approach, we can create a hierarchy for the parameters and determine their importance. The results of the survey are shown in Figures 1 and 2. The first one shows box-plots of the results showing the dispersion in the importance of the parameter for the different professionals tend to prioritize different variables when designing the structural elements, this dispersion has to be taken into account to weigh the importance of each parameter. From Figure 2 we can gather the parameters into three different main groups regarding the importance. These clusters have been shown in the figure with the colored lines. The first group consists of two parameters, height and type of construction, both of them are related to the relationship of the beam with their environment, their mean values oscillate between one and four. The second group contains all the parameters regarding both rebars and type of beam. The third and last group covers the rest of the parameters, these group also has the biggest deviations in the box-plot diagram, so different professionals give different attention to them. During the survey, the professionals were also asked about other parameters that were not taken into account in the research. Some of the professionals suggested the size of the arid as a parameter to be added. After further study, this has been discarded, as its effects are taken into account considering the number of rebars and the consistency of the concrete. There is also the fact that in some areas the size of the arid is determined by the availability and not chosen by the professional, so it can be considered an external factor instead of a parameter. From this survey, we can extract a hierarchy based upon the experience of the professionals and how they evaluate the constructability in a concrete beam and then establish a way to measure it. Figure 3 shows the correspondence between the mean value and the standard deviation for each parameter. A parameter with lower mean has been given more importance by the respondents and a lower standard deviation implies more agreement among the professionals in the importance of a certain parameter.

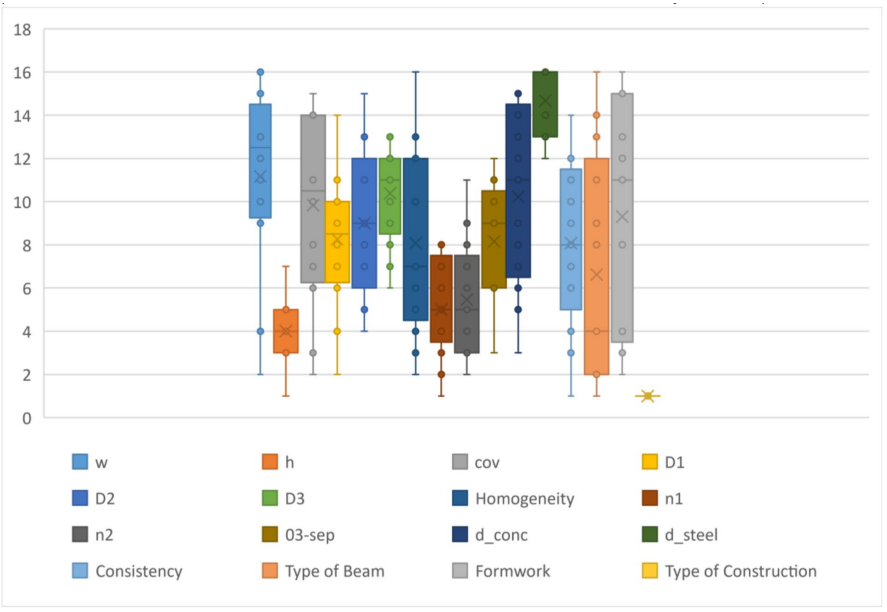

Figure 2. Box-plot diagram with the results of the survey

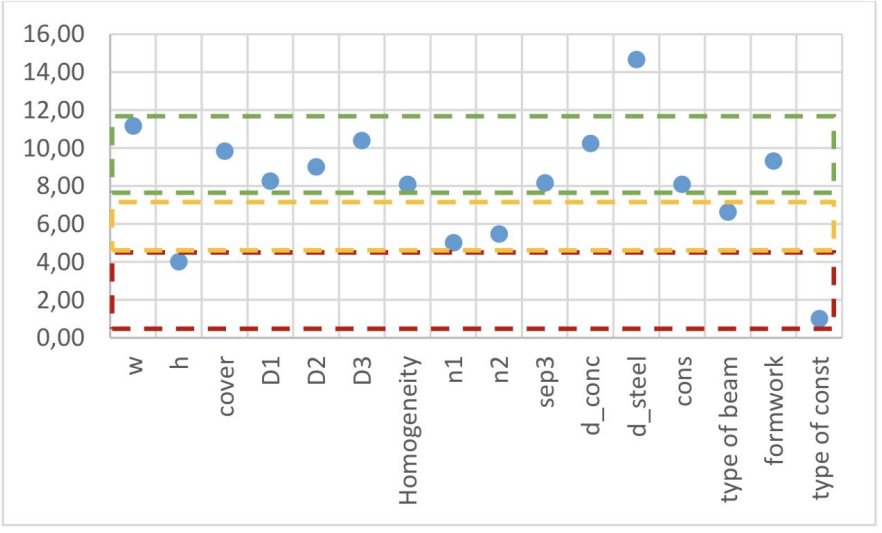

Figure 3. Mean value for each parameter

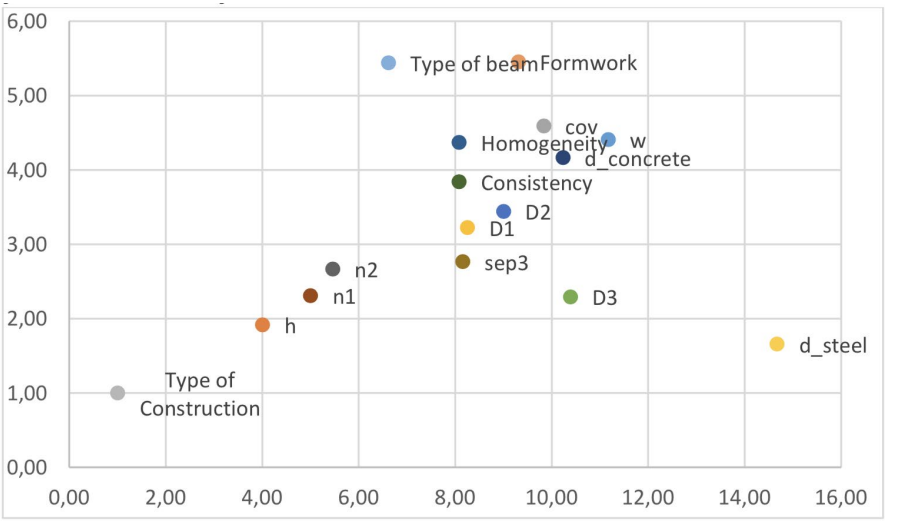

Figure 4. Cluster analysis of the mean and standard deviation for each parameter

2.2. Hierarchy for constructability

From the figure, we can see a tendency between the mean and the deviation, parameters with more importance are also important for most of the interviewees in almost a linear regression. This phenomenon is more accused in the first group of parameters and defines two sets of clusters encircled in the figure, there is a parameter outside of this phenomenon "steel density" which has been considered by most of professionals as the least valuable one. The parameter which has been given more importance is the "type of construction". The first cluster is the one with higher importance and it will be considered in that way when considering the constructability analysis, either way, the second cluster is also relevant and influential even if it has less impact on the criterion. The "steel density" parameter has been unfavored by most of the professionals given its position, for this reason, we are going to discard it as its influence can be explained through other parameters that have a bigger impact on the whole environment. The "type of construction" parameter has been proved to have a lot of influence on the constructability and after analyzing the data its two values cannot be compared between them, so it is going to be considered as an external factor to achieve a more accurate result.

3. DISCUSSION

3.1. Units of measurement

After sorting the parameters and weighing them we are in need to establish a measurement system. Typically, an optimization criterion can be quantified using a certain unit, like currency when studying the economic aspect, the mass of carbon dioxide emitted during production

or watts consumed among others for sustainability, but this cannot be done with the constructability as different units are taken into account. When assessing the constructability every parameter has its own unit and some of them are discrete variables dependent on the amount of something, like rebars placed. These quantifications cannot be mixed in a direct way as it will create inconsistency in the measurement. There are two possibilities to unify the parameters in an indirect way: currency value and working time, both related to the efficiency of the working crew. Both of them can assess constructability in an indirect way. The economic value is usually also taken into account when using a multicriteria optimization algorithm, but it is hard to completely take into account the prize for the working crew exactly as can overload the computer with data or create inaccuracies due to too many factors taken into account. Other possibilities based on discrete quantitative indirect approaches can be used to evaluate the constructability as working crew time but it is hard to define.

3.2. Quantifying the constructability

From the survey results and the cluster analysis, we can confirm that there are factors which influence more than others The hierarchy shows which of them need more weight than the rest, we can also estimate that the first cluster is roughly twice as important as the second, because their total mean values differ in that proportion. Optimization algorithms tend to overload the computer creating a huge population that must be handled and analyzed at the same time. Computational time is a determining factor in them and adjusting the methodology to evaluate the criteria is crucial. Depending on the research it is possible that it is beneficial to reduce the accuracy to favor the computational time. Through this paper, we have seen that constructability is not universal, either by the perception of the professionals or the units that can be measured. We are going to define several methods to quantify the constructability in a concrete beam, allowing us to adjust the computational cost to the necessities. The different proposed methods are sorted from lower to higher computational cost and data needed to perform the analysis.

- Number of rebar reinforcements: The most influential parameters in the constructability are the rebars. The raw number of them is directly related to its constructability. An element with more rebars will need a bigger resource investment to be built as it gains complexity. So, the element with fewer rebars has more constructability than the rest. This criterion can be exposed by the following formula:

$$C_1 = n1 + n2 + \frac{sep3}{l}$$

-Number of rebar reinforcements modified: Considering not only the rebar number but the difference in diameter among them creating and adding the height of the element into the criteria a more accurate scale can be obtained. This takes into account all the parameters existent in the first cluster and weighs them based upon its importance. The formula is the following:

$$C_2 = h \cdot (n1 \cdot D1 + n2 \cdot D2 + \frac{sep3}{l} \cdot D3)$$

This formula does not have any direct physical meaning but weighs the criteria following the intended parameters. Larger values for the parameters reduce the constructability of the element. Each rebar is weighed by its diameter, as thicker rebars are harder to be placed, in the same way, the height increases

the constructability as it lowers showing the negative effect of it. It is also low in computational cost and considers the most influential parameters.

-Working time invested

As previously discussed, one of the most accurate values for the constructability is the time spent by the working crew to build the element. This criterion quantifies the number of hours needed to accomplish it and takes into account the different considered factors and interactions between the defined parameters. The standard amount of time for each of the considered operations differs from country to country, but there are databases where an accurate estimation can be obtained. This criterion is split into different sections.

$$C_{3a} = [(h \cdot w + cov)] \cdot t_{3a}$$

The first section takes into account the time spent in shaping the element or how its external shape and contour factors affects the time spent. The parameter t3a measures the time spent to position the element in the building measures in m^2/h.

$$C_{3b} = [\sigma_{hom} \cdot \left(n1 \cdot D1 + n2 \cdot D2 + \frac{sep3}{l} \cdot D3\right) \cdot (con.)] \cdot t_{3b}$$

$$Homogeneity\ (\sigma_{hom}) = \sqrt{\frac{1}{n-1}\sum_{i=1}^{n}(D_i - \bar{D})^2}$$

$$Values\ for\ consistency\ (con):\ (based\ on\ the\ slump\ test\ results) \begin{cases} (0-2)cm. \rightarrow 1.1 \\ (3-5)cm. \rightarrow 1.05 \\ (6-9)cm. \rightarrow 1.00 \\ (10-15)cm. \rightarrow 0.95 \\ (16-20)cm. \rightarrow 0.90 \end{cases}$$

The second section quantifies the amount of time spent to put the rebars into the right place and distribute them consistently. It takes into account the loss of time due to using different rebar sizes and its difficulty in a placement through the homogeneity of them and also the amount of time spent when dumping the concrete in the cast and its interaction with the rebars. The parameter t3b considers the time spent to develop all these tasks.

$$if\ h = slab\ height$$
$$C_{3c} = (l \cdot w) \cdot t_{3c}$$

$$if\ h > slab\ height$$
$$C_{3c} = [(l \cdot w) + 2 \cdot (l \cdot (h - slab\ height))] \cdot t_{3c}$$

The third and last section takes into account the time spent in the construction of the formwork and it varies depending on if the element has a higher height than the one in the slab that it is in. The parameter t_{3c} measures the hours spent to build the formwork expressed in m^2/h. With these three sections we can define the constructability criterion like the following:

$$C_3 = C_{3a} + C_{3b} + C_{3c}$$

-Working time simplified

A simplified version to quantify the working crew time can be done assuming a relationship between the steel weight in the section of the element. The parameter t4 measures the mean value to build a certain section based on this assumption and is obtained through databases and increased gradually as the amount of steel increases. With this simplification, we can quantify the constructability with the following formula.

$$C_4 = \left[\left(\left(\sum_{i=1}^{n} n_n \cdot [\left(\frac{D_n}{2}\right)^2 \cdot \pi]\right) \cdot \gamma_{steel}\right)/(h \cdot w)\right] \cdot t_4$$

CONCLUSION

The AEC Industry has a tendency to automation and improving the procedures by using digital tools such as BIM environments and Digital Twins. For this several BPS Tools are in development to analyze the building requirements and improve, and optimization algorithms are being used in connection with them to help the professionals to achieve better designs.

In this paper, we have explored the parameters necessary to define a new criterion, the constructability for a specific structural problem, a concrete beam. By using a survey a hierarchy among the different parameters has been created and discovered two sets of parameters This methodology can be used to define the same criterion for a different structural element.

Using this previous survey, four distinct ways to measure the constructability have been defined and their strong and weak points explored to adjust the accuracy of the criterion to the optimization purpose where it is going to be used.

Future Research

The model presented in this paper is not a fully developed model, as we have assumed some simplifications. The different mathematical models for the constructability that have been proposed can be refined taking into account more parameters and will achieve a more accurate result, probably at the cost of more computation time. Further research is required to create a mathematical model able to handle a discrete approach for the rebar disposition, including the analysis of each diameter and position individually.

A comparison among the results obtained with the four definitions for constructability in this paper can be done and tested with real results to properly adjust the mathematical models. This comparison of results will show the ideal cases of optimization for each of the four models.

Also, the movement of the crew along the whole building site and the position of the element itself can be taken into account, to assist the constructability for the complete structure and not to each of the elements or the reduction of trims in the rebars to optimize not only the working time but also to reduce the waste. Further study is required to be able to mix both types of construction, usually, precast elements tend to have better constructability because the process has a higher level of automation, but this is not always true for simpler elements and the different interaction between the parameters has to be taken into account.

PAPER #5.07

THE SUSTAINABLE WHITE CITY

Paolo De Marco[a]
[a] Universitat Politècnica de València, Valencia, Spain

ABSTRACT

The history of architecture and urban planning tells of white cities, whose chromatic characteristic derives from the use of local resources (stone, lime) and which unconsciously responded to principles of environmental sustainability. During the first half of the twentieth century, some European countries undertook economic and social policies aimed at the agricultural development of the territories and a consequent repopulation of the countryside. Especially in the south of Spain, numerous white-colored cities were founded.
Global warming issues call into question the current organization of the city, which must renew itself and create comfortable and compatible living conditions with long-term development. Today the importance of color is reaffirmed in the possibility of re-establishing the contemporary city according to principles of environmental and economic sustainability. In the field of architectural design, one of the central aspects to consider is the amount of energy that buildings need to cool down, and the amount of heat they emit into the atmosphere. Especially in areas with warm climates, the energy consumption of a building is determined by its thermal insulation properties, which mainly depend on the material and color of the external surfaces. The use of white color allows to reduce the heat absorbed by buildings, with lower energy consumption and emissions; furthermore, the amount of heat re-emitted in the atmosphere is reduced, with the possibility of decrease the urban heat island effect.
This simple chromatic principle of architecture can be extended to the urban scale thanks to a wide range of products and technologies, so that some cities have already undertaken a chromatic conversion.
The contribution tells the idea of a sustainable white city and, starting from examples of built architecture, it defines the possible principles, materials, techniques and technologies available for the design of architecture and the contemporary city.

KEYWORDS

Architecture; design; tradition; innovation; color.

1. TRADITION AND CONTINUITY OF THE WHITE COLOR

The origins of the use of white in architecture and the arts are distant and difficult to trace, related to primordial values and ancient ideals such as the sacred and purity, which give this particular color an almost universal meaning (Zammerini 2014). The history of architecture and urban planning tells of ancient white cities, whose chromatic characteristic derives from the use of local resources (stone, lime), a traditional practice that has above all hygienic reasons but which, almost unconsciously, responds to principles of environmental sustainability. In fact, in the thinking of vernacular architects, the holistic conception of the project is completely synergistic with the methods and materials available. The practice of whitewashing the walls of buildings spread throughout the Mediterranean area mainly during the eighteenth century, thanks to the hygienic properties of lime; at the same time, the white coating protects the masonry, decreases

solar radiation and improves the thermal conditions of the buildings. For these reasons, for centuries white color can be considered one of the characteristics of Mediterranean architecture and cities, which also corresponds to a spatial principle based on the construction of elementary and compact volumes - another principle of economy that also has the effect of reducing the exposed surfaces - the adoption of shaded patios and courtyards, and the creation of a few and measured openings, which allow lighting without heating. But the color white is also strongly linked to classical culture: for many centuries (and until the early 19th) the idea that Greek sculpture and architecture were white, idealized in the monochrome of Parian marble, resisted. In the eighteenth century, the tales of the *Grand Tours* and the passion for antiquities emphasize a mythical ideal of Greek art that Johann Joachim Winckelmann encoded in "noble simplicity and quiet grandeur" in which white enhances the beauty and perfection of forms (Winckelmann 1994, 117). Despite Winckelmann's historical reconstructions then turn out to be erroneous, these aesthetic theories are followed by most of the neoclassicals, influencing the plastic arts and architecture for a long time up to the present day (Collins 1970, 111-116). In the revolution wrought by the Modern Movement, white is the background of a page on which to write a new story: it expresses the cleanliness of the surfaces (to which the absence of ornament and the need for hygiene refer), the purity of forms and principles, the concepts of abstraction and denaturalization of volumes and materials[1]. Subsequently, the events of white in some cases are directly linked to the nationalist ideals of the ideologically similar governments of Italy, Spain and Portugal, where a new trend arises that leads to the study and recovery of popular building traditions, to the interest in spontaneous and anonymous architecture. This trend will have its peak, at the height of its diffusion, in the famous Bernard Rudofsky's *Architecture Without Architects* exhibition at the MoMA in New York and in the homonymous book published in 1964. In Spain, during the first half of the twentieth century, as part of a program for the repopulation of rural areas (initiative common to many nations), the color white asserted itself as a particular character in the architecture of newly founded cities. In this context, white experiences a great diffusion as a common feature of the various colonizations, predominant in these neo-popular architectures, which certainly refer to the elements of traditional architecture of southern Spain, but which starting from these introduce interesting linguistic innovations, so much so that it can be considered a pioneering experience on the theme of the rural house and on urban planning (Centellas Soler 2009). Among the many works of interest, those by José Luis Fernández del Amo and Alejandro De la Sota stand out. The projects of the *pueblos* extend the chromatic principle of white to the entire new settlement and, thanks to the sensitivity of their designers, they become bearers of the architectural concerns of the time, certainly extendable to the rest of European culture but, by their nature, referable to the specificity of contexts. This architecture built with reduced economic resources, with essential and humble tools (both design and technical-construction), rediscovers the true *spirit of necessity* that guides the *highest* forms of the art of building. A pioneering and experimental experience, capable of influencing the development of architectural and urban research from the twentieth century up to contemporaneity. So, the history of the white color in architecture is clearly linked to the history of construction materials, techniques and technologies that, as they evolve, contribute to the creation of forms, styles, movements and trends. The events of white architecture - and not only of it - cannot

[1] On the issues of color in modern architecture, a relevant contribution is that of Cramer Ned, "It was never white, anyway", in Architecture n. 88, 88-91. On the same theme, an analysis of the context of modernity is provided by Juan Serra Lluch, "Il mito del colore bianco nel Movimento Moderno", in Disegnare: Idee Immagini n. 41, 66-77.

be separated from the cultural evolution in the succession of the epochs, from the specificity of the places, from the psychological meaning, as they cannot be understood without considering the technological progress of the architecture. Today, new materials and innovative techniques allow to think about further applications of the color white in architecture - combining spatial research and sustainable thinking - potentially extendable, thanks to a wide variety of solutions, to the entire city.

2. SUSTAINABILITY OF COLOR

2.1. Physical factors

Global warming issues call into question the current organization of the city, which must renew itself and create comfortable and compatible living conditions with long-term development. Today the importance of color is reaffirmed in the possibility of re-establishing the contemporary city according to principles of environmental and economic sustainability (De Marco, Margagliotta 2018). In the field of architectural design, one of the central aspects to consider is the amount of energy that buildings need to cool down, and the amount of heat they emit into the atmosphere. Especially in areas with warm climates, the energy consumption of a building is determined by its thermal insulation properties, which also depend on the material and color of the external surfaces. The use of white color allows to reduce the heat absorbed by buildings, with lower energy consumption and emissions; furthermore, the amount of heat re-emitted in the atmosphere is reduced, with the possibility of decrease the *urban heat island* effect. In fact, regardless of the material and construction technique chosen for each architecture, the use of white offers some advantages for the sustainability of buildings. It can be said, in fact, that white is the greenest color in architecture, both for the exterior and the interior of the building (Lechner 2015, 120).

The physical properties of the color white make it particularly efficient from an energy point of view and therefore sustainable. If we are to consider temperatures, the most sensitive surfaces to the absorption of sunlight are the ceilings. The greater reflection of light rays causes, for example, that white ceilings heat half of black ones. This characteristic is quantifiable through solar reflection, also known as albedo, that is, a parameter that measures the capacity of a surface to reflect solar radiation. An albedo equal to 0 (zero) indicates a surface that does not reflect sunlight and, therefore, absorbs it in its entirety, with a consequent increase in temperature; conversely, an albedo value of 1 (one) indicates that sunlight is fully reflected. Table 1 indicates the albedo values for some surfaces commonly used in construction, of which it is observed that the white color has an albedo that varies from 0.5 to 0.9 (50% - 90% solar reflection), depending on the roughness surface and cleanliness. The so-called cool roofs are precisely the roofs that remain cool, or rather less warm, than traditional roofs. Especially in hot climates, paying attention to these aspects of construction can significantly reduce building overheating, resulting in lower costs to cool it down. At the same time, the widespread use of cool roofs can affect the urban scale for the reduction of the already mentioned *heat island* effect. Even on vertical surfaces, the white color reduces heat, two-thirds less compared to a black wall. If applied in buildings arranged in narrow streets, the white color increases the diffusion of natural light on the lower floors. In general, opaque white surfaces can be considered more sustainable than glazed ones, even if they are protected with sunscreens or shading elements. These briefly enumerated principles could be applied to the project of architectures more suitable to the climate and, ultimately, more sustainable; In any case, to more accurately quantify the reduction in temperatures, it is necessary to evaluate not only the color of the material, but also its thermal transmittance properties.

Building surface	% Albedo
White paint	50-90
Highly reflective roof	60-70
Colored paint	10-40
Brick and stone	10-40
Concrete	10-40
Red/brown tile roof	10-40
Grass	20-30
Trees	10-20
Corrugated roof	10-20
Tar and gravel roof	5-20
Asphalt paving	5-20

Table 1. Albedo of typical building surfaces (Lechner 2015)

2.2. Space and perception

According to some studies on human response to the color of its environment, white should not be chosen as the color of a space where people stay for a long time, such as offices or classrooms (Birren 1978; Mahnke 1996). This observation is not based on aesthetic but ergonomic reasons: the use of white - which has the highest light reflection factor of all other colors - associated with high levels of illumination (natural or artificial) and glossy and reflective finishes, it can produce glare and, consequently, a decrease in environmental comfort, causing visual, mental and emotional fatigue. In fact, to adapt to very bright environments, the eye muscles continuously act to reduce the opening of the pupil, with the consequent rapid tiredness. If the chromatic component confers a particular dimension in the architecture, this is even more true if the color is white (Cage 1993). In fact, white has the ability to minimize solar radiation (with the clear advantages previously described), improve the perception of shapes, expand spaces, enhance the play of light and shadow; in contemporary architecture, the use of white can refer to ideologies and specific spatial and linguistic investigations. According to design choices, today more than ever materials are projects in themselves (Deplazes 2013); in addition to building the architecture, the material qualify the space with its perceptual qualities (opacity-transparency, smoothness-porosity, temperature), so that even color must be considered an architectural material. The higher performance demands in contemporary buildings determine a constant drive to implement product quality and improve traditional techniques. These requests also lead to the adoption of materials that have been tested in other scientific fields and then, in some cases, conduce to the definition of exclusive materials for a special work, which can then be extended for a wider production. But the sustainability of architecture does not only concern the energy performance of a building or a set of these. A profoundly sustainable thought must also consider the influence of the project on the landscape (urban and otherwise), its correspondence to the cultural context and the relationship with the construction and living traditions. White architecture, in this sense, refers to universal values capable of adapting to the different conditions of the places.

3. APPLICATIONS FOR ARCHITECTURE AND THE CITY

This simple chromatic principle very present in the architecture of individual buildings may be extended to the urban scale thanks to a wide range of products and technologies, so much so that some cities have already undertaken a chromatic reconversion, intervening on the space and on the existing buildings, as a first step towards a profound change in the paradigms of building and urban design. Below some realizations are analyzed, chosen to represent the principles of white in architecture and which, thanks

to the qualities they emanate, allow the specification of the range of products available for the sustainability of white, by relating their uses and the possibilities they offer to the different design purposes of architectures. It is then made up of a catalog of solutions, materials, techniques and technologies available for the architectural project and the contemporary city.

3.1. Conversion of existing places

For the intervention on existing buildings (especially for refurbishment and renovation of buildings with shape constraints) an important contribution to the use of white in architecture comes from water-repellent and self-cleaning paints, which can also have insulating properties. A particular case is that of the liquid ceramic insulation that Elisa Valero Ramos has used for the construction of her own studio on a small plot in the center of Granada (Fig. 1). The availability of only 3.60 meters of depth, has led to reduce the thickness of the wall towards the street through the use of this special insulation, put into work as a simple painting. Composed of spherical microgranules of special ceramic, the liquid insulation uniformly covers any surface, forming a continuous, flexible and crack-free layer, which in a thickness of less than 1 mm provides insulation equivalent to 10 centimeters of polystyrene. From the point of view of the project, the use of white inserts the building into the chromatic and material continuity of its surroundings and, in other respects, adequately insulates it. As for the sustainable conversion of horizontal surfaces, flat or sloping roofs, the aforementioned cool roof technology includes a wide range of high solar reflectance paints that can reduce the surface temperature up to 30 °C. With regard to circulation spaces, however, the market offers a range of high-performance water-based sealants, directly applicable to existing surfaces (including asphalt) as a normal waterproofing product. The white color and the high reflectivity - although they reduce their effectiveness if not cleaned - allow to significantly reduce the surface temperature and consequently that of the environment, also increasing the night visibility of the streets without producing glare[2].

Figure 1. Elisa Valero Ramos studio in Calle Belén, Granada.

[2] In 2019, the city of Los Angeles began testing this particular technology on 15 stretches of road.

3.2. Design of new spaces

For the external horizontal surfaces (car parks, secondary roads, paths and pedestrian areas or green ways), there are interesting applications of white draining concrete, as in the case of Italcementi i.lab center in Bergamo, designed by Richard Meier (Fig. 2). The building - also entirely white thanks to the use of a special photocatalytic concrete - is part of a large natural park, accessible by walkways, ramps and outdoor spaces made of white draining concrete. This technology, thanks to the special mix-design, allows to safeguard the aquifers and, thanks to a high albedo, reach significantly lower temperatures than asphaltic floors, with the possibility of reducing the heat island effect typical of metropolitan areas. Regarding the building envelope, plaster still represents the most widespread technique for white architecture, due to its low costs and ease of application, especially for small-scale interventions (Reichel, Hochberg, Köpke 2007). However, to achieve the performance required for current architecture, the plasters acquire increasingly high insulating and breathable properties, obtaining interesting characteristics of durability and sustainability. One of the most interesting technologies applied to renderings is photocatalytic, which today is also being used in other finishing materials for architecture (such as the previously mentioned white concrete). In fact, the photocatalytic plaster is particularly white and shiny due to the presence of titanium dioxide (TiO_2); This chemical compound makes the plaster active, decomposing the microorganisms present in the air: with a process similar to the chlorophyll photosynthesis, air and light oxidize polluting substances and fine particles, forming harmless residues. These compounds are washed away by the rain, thus obtaining anti-pollutant, antibacterial and self-cleaning properties. With a greater durability, the photocatalytic plaster also allows to prolong its chromatic characteristics and consequently the physical effectiveness of its whiteness. The use of ceramics in architecture dates back to an ancient tradition, particularly widespread in countries and cultures with Arab influence. In its contemporary use, the ceramic material is renewed, so that some elements - today available in large sizes and reduced thicknesses - can be designed according to specific needs. Some producers also manufacture ceramic pieces with photocatalytic characteristics (also in this case with the use of titanium dioxide) that endow the surfaces with antibacterial, anti-pollution, anti-odor and self-cleaning properties. Among the examples of contemporary applications, always in the context of white architecture, the rental housing building in Gójar designed by Elisa Valero stands out (Fig. 3), which on the exterior, both on the facades and on the roof, is clad with alveolar ceramic: stoneware pieces traversed inside by alveoli that improve insulation; Research for sustainability has also led to the use of an enamel that is characterized by its capacity to capture CO_2.

Figure 2. Italcementi i.lab in Begamo, by Richard Meier.

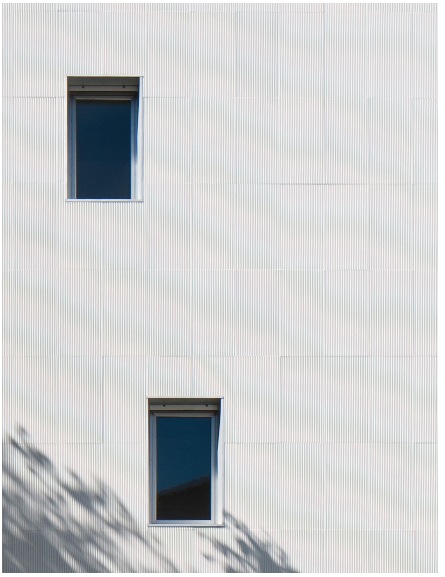

Figure 3. Housing building in Gójar, by Elisa Valero.

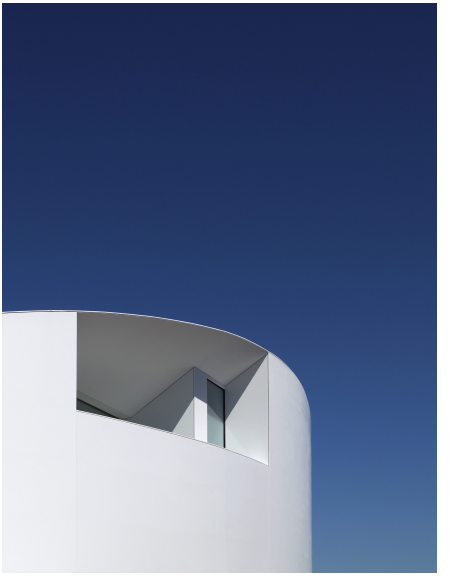

Figure 4. Balint house in Valencia, by Fran Silvestre.

Figure 5. EDP Headquarters in Lisbon, by Aires Mateus.

To remain in the context of Mediterranean architecture, the *Balint house* project by Fran Silvestre Arquitectos studio in Valencia is also interesting (Fig. 4). The white cladding of the unusual curvilinear geometry is made with *solid surface* - a technology widely used for the construction of countertops and sanitary accessories, due to its hygienic properties and the absence of joints. The elliptical and shiny house appears as a monolithic sculptural piece, endowed with a continuous ventilated façade, which also covers the curved roof in continuity. Among the contemporary applications of white concrete coatings, the technology of glass fiber reinforced panels (*Glassfiber Reinforced Concrete - GRC*) is widespread. Present in the architectural field for decades, recent research has improved the characteristics of GRC - greater mechanical resistance and extreme lightness - and has acquired the possibility of prefabricating elements with different shapes and sizes. These technical characteristics, together with the aesthetic qualities, have made GRC panels widely used in white architecture, especially in large-scale projects with complex geometry. The architects Aires Mateus Associados, who often render their small houses white, also used GRC technology in the project of the new headquarters of the electric company EDP in Lisbon, on the banks of the Tagus (Fig. 5): the large building consists of two tall glass blocks whose steel structure is clad with special GRC elements. Oriented to the southwest, these white ribbons run along the facades and cover the square between the blocks, setting the rhythm of the entire composition and solving, with a single expressive gesture, the entire project. The GRC elements act as sunscreens and protect spaces from excessive radiation, varying their size according to the internals, while the diagonal orientation generates a transparency effect that changes in relation to the position of the observer. White, often conceived as an opaque, full and static material, thanks to GRC panels, can express dynamic shapes and combine in an innovative way with transparency and light.

In the historical context of Berlin's Museum Island, David Chipperfield has recently completed a long series of interventions with the James Simon Galerie (Fig. 6). While exposed concrete is widely used in the interiors of the building, the exterior parts are characterized by architectural elements deduced by the neighboring constructions of Schinkel and Stüler, made of *Engineered stone*, a composite material made of stone fragments (in this case limestone and sandstone) joined by a resin. This technology - used above all for the construction of kitchen and bathroom countertops - makes it possible to use the residues from stone treatment and produce elements of large sizes and limited thickness. Finally, some less common materials in contemporary construction are mentioned, which are nevertheless the object of interesting research: fabrics, membranes and translucent polycarbonates, which come to architecture through technological transfer (as in the case of polytetrafluoroethylene, commercially known as *Teflon*) and they come to define new poetics that no longer root the building to the earth (and to history) but are projected towards new concepts of duration and dissolving forms. An example is the *experimental house* at Meme Meadows Center, built by Kengo Kuma, which uses a layer of transparent membranes to provide thermal insulation suitable for the harsh winters of northern Japan (Fig. 7). If the large sloping roof, as well as the larch wood structure, is derived from the traditional constructions of the region (the *chise*, home of the Ainu population), the construction is completed with the use of technologically advanced materials. The outer membrane is a polyester cloth painted with fluorocarbon (colorless substance with high hydrophobic properties), the inner thermal insulation is made of polyester fiber obtained from recycled polyethylene (PET) bottles, while the removable inner membrane is made of polyester cloth. fiberglass. Therefore, the use of transparent plastic materials defines a semi-opaque white volume, capable of being passed through by light.

CONCLUSION

Today, also due to the recent vicissitudes linked to the pandemic unfortunately still underway, culture, economy and society have returned to discuss the city, its population density, its morphological characteristics and the quality of life of its inhabitants: in other words, we have returned to talk about the sustainability of urban living. The proposal for the displacement of the population from the city for the rediscovery of life in the countryside, supported by some internationally renowned designers, nevertheless appears as an initiative which, if not controlled, could have disastrous effects on the territory. It is useful, however, to return to reflect on the city, first of all on how to intervene on the existing, to make it more responsive to the future vision of living; secondly, on the design of new buildings, public and private spaces. It is from this perspective that color can be rediscovered as an elementary principle of sustainability, as the constructive wisdom of traditional Mediterranean architecture reminds us. Nevertheless, the sustainability of white does not only concern the surface (or the *skin*) of the city, but implicitly includes principles of essentiality and economy for the living space which, consequently, influence people's lifestyles. The sustainable principle of white would thus represent an initiative of rapid feasibility and immediate results, albeit aware that probably, a sustainable model for the city of the future must address much more complex problems. Extending these principles to the urban scale, then, does not mean wrapping the metropolis with a veil of homogeneous, indifferent candor; on the contrary, as demonstrated by the different architectural solutions mentioned above, there are different ways in which white can be used, in the most suitable forms also in relation to particular contexts. From this point of view, white in architecture is not a simple color but instead represents a spatial principle, with technical and technological implications. "Sustainable design has also become a new marketing strategy both among designers and developers" - claims Juhani Pallasmaa (2010, 34) - describing the trend that favors the proliferation of projects that superficially tackle the issue of sustainability, for example, by adorning condominiums with vegetation but without actually intervening on the quality of the living space. A risk, that of *decorativism*, which in some cases also affects white architecture since, unfortunately, the current sustainability assessment system does not promote environmental policies and truly ecological thoughts. In any case, the search for sustainability must be approached from a holistic point of view, which cannot ignore formal qualities: "aesthetics is the mother of ethics", argues the poet and Nobel Joseph Brodsky, for which sustainability in architecture it will find, together with its own aesthetic, its ethical principles.

PAPER #5.08

MACROCRITERIA FOR COMPILING DATA ON CO2 EMISSIONS IN BUILDING MATERIALS UNDER EPD, EN, ISO; CATALOG -IVE.

Begoña Serrano Lanzarote[a], César Emmanuel Arguedas Garro[a,b]
[a]Instituto Valenciano de la Edificación, Valencia, Spain
[b]Universitat Politècnica de València, Valencia, Spain

ABSTRACT

The objective is to carry out a macro-classification and qualification criteria for the selection of useful data on CO2 emissions in building materials, to be compiled in material databases. It is determined that CO2 emission data are necessary in building technology when selecting a material in relation to environmental impact (Hypothesis 1), the classification of emission data is useful for retrofitting, designing or building systems, for example in facades (Hypothesis 2).
Methodology. The data on CO2 emissions were classified in a representative sample of 829 materials studied from the Catalogue of building solutions, from the Construction Database of the *Instituto Valenciano de Edificación*-IVE, Annex I: Thermal and acoustic insulation (2019), Valencia, Spain ; Analyzing the environmental statements of existing products (EPD) with data on the global warming potential GWP [kg CO2 eq], the information was qualified with 3 evaluation points: 1) use of UNE-EN 15804: 1.00 point, 2) use of EN ISO 14025: 1.00 point, 3) EPD and data on current dates: 1.00 point; being for the IVE catalogue: 0.00 to <2.00 (Not useful); > 3.00 (Useful). The results of the qualification and the obtaining of 3 points provided useful emissions data according to: a) GWP [kg CO2 eq], b) EPD, Standard and ISO, c) current public data.
Conclusions. From the sample of 829 materials in the IVE's catalogue database, about 214 EPD of materials were found in the market, with useful data of CO2 emissions according to European Union regulations; information to be compiled regarding the environmental impact of the material.

KEYWORDS

Emissions; materials; embedded; carbon; energy.

INTRODUCTION

The scope of this study is to identify the criteria for compiling data on CO2 emissions, to be considered within the information of the catalogue of constructive solutions *(Construction Database 2019)* developed by the Valencia Institute of Building-IVE and successive editions (2020), providing specific data, in the building materials applicable in facades, envelopes, thermal capacity and their impact at the time of selecting the material, in relation to nearly zero-energy buildings and knowledge of embodied carbon. The purpose is to establish criteria for the evaluation of GHG data in relation to building material databases.
The comparison and selection of the data is obtained from specific criteria of Environmental Product Declarations- EPD(s), according of the ISO regulations *(ISO, I. 14020 2000)*, the data of CO2 emissions, were identified according to the standard *(UNE-EN 15804 2012)* and *(EN ISO 14025 2010),* through which data were obtained, coming from processes of calculation of emissions, in which the organizations or product companies, indicate data of GHG, according to the global warming potential GWP [kg CO2

eq]. The data of CO2 emissions reported in the EPD(s), are varied, so the classification and qualification of the information was established, to determine its usefulness for the *(Construction Database 2019)* of the Valencia Institute of Building - IVE.
This study is based on a compilation of CO2 data developed in the Environmental Product Declarations; the EPD(s) are regulated from the International Organization for Standardization -ISO(s) (Murphy, Yates 2009), European Union standards and technical sheets; the research defined the hypothesis in the use of a macro-compilation criterion, to demonstrate the usefulness of the data based on the calculations of GHG emissions.

1. DESCRIPTION OF THE CASE STUDY IN CONTEXT

1.1. Embodied carbon and CO2 emissions (energy matrix, production of EPD(s))

The life cycle of materials, as well as embedded energy, identifies the relationship between the energy production matrix and the production process of a material, where the impact of the carbon emissions of a material is also related to the energy matrix on which its production system is based. In the case of countries where the energy matrix is based on fossil fuel sources, the result not only implies a building material based on fossil fuels, but also a production of this material with high CO2 emissions, also establishing an increase in the embodied energy. The energy matrix on which the industry depends on a building material and the use of materials, links it to low or high emissions, the data on energy consumption in the process of producing a material, are reflected in the cycle of the embedded energy and identified in the EPD(s) according to *(ISO, I. 14020 2000), (UNE-EN 15804 2012)* and *(EN ISO 14025 2010)*.

In the international sphere, countries such as Costa Rica *(ICE Group promotes national electromobility with the presentation of a new fleet, consulted on May 1, 2019, https:// presidencia.go.cr),* Iceland, Norway, Portugal, identify successful cases in which the energy matrix is reaching 99% or 100% of production based on renewable energy, it is an achievement of locally produced stationary energy where the objective of carbon neutrality is a success. Another similar case occurs with Uruguay and Lesotho, which also have around 100% of energy production based on renewable energies; according to (Clarke 2017), the case of Iceland is also identified, as an example for the industrialized countries of the planet, for producing clean energy, where stationary energy is 99% renewable energy.
The energy consumption for the elaboration of a building product evidenced in the EPD(s) *(ISO, I. 14020 2000),* is associated with the energy matrix on which its production depends, it implies emissions according to the energy used and the Life Cycle. Building materials have CO2 data, which in the case of Spain are in turn equivalent in emissions from energy use, such as Natural Gas, Diesel emissions, G. Generator, Diesel and Gasoline emissions, Fugitive and Process Emissions, Emissions from Electrical Energy, according to *(Greenhouse Gas Emissions Report 2016)*. The knowledge of CO2 data is related to sustainable design, the lack of production of materials with emissions data generates a problem in contemporary design that aims to reduce the environmental impact of a construction.

1.2. Standard(s) and ISO(s), GHG emissions and criteria for the calculation of CO2 eq

The objective of a low-carbon global economy, seeks to establish criteria and methods for the analysis of the carbon footprint, which allows to establish common policies and regulations that are unified in a homogeneous way,

standards in the European Union establish unified criteria *(UNE-EN 15804 2012)*; in the case of Spain, some management policies were those of the Royal Decree 163/2014, of March 14, relating to the registration of the carbon footprint, compensation and absorption of carbon dioxide projects, published in the BOE on 29 March 2014 *(Royal Decree-Law 2014)*.

The calculation of the carbon footprint after the effect of greenhouse gases has involved both organizations and the building sector, in the case of the European Union, the standards *(UNE-EN ISO 14064-1 2012), (UNE-EN ISO 14064-2 2012), (UNE-EN ISO 14064-3 2012),* have evolved towards an improvement in the calculation of greenhouse gases. According to the standard *(UNE-EN ISO 14064-2 2012)* GHG are understood to be gaseous compounds in the atmosphere, both natural and anthropogenic, that retain and emit radiation at wavelengths, which occur in the spectrum of infrared radiation emitted by the planet's surface, clouds and atmospheric layer *(UNE-EN ISO 14064-2 2012)*.

According to the standard *(UNE-EN ISO 14064-2 2012)*, in point "5.8 Quantification of emissions reduction - increase in GHG absorption", the ton is used as a unit of measurement, converted into the amount of each type of GHG in tons of carbon equivalent -CO2e, using the global warming potentials (PCG). The global warming potentials of PCG greenhouse gases, for a 100 year projection, published by the Intergovernmental Panel on Climate Change *(IPCC guidelines for national greenhouse gas inventories: reporting instruction, 1997)*, are the basis for the current calculation of CO2 equivalent GHG emissions. The standards *(UNE-EN ISO 14064-1 2012), (UNE-EN ISO 14064-2 2012), (UNE-EN ISO 14064-3 2012),* have been part of a standardized evolution for the quantification of greenhouse gases and carbon footprint, during production processes or activities; as of 2019, these standards have been replaced by the standards *(UNE-EN ISO 14064-1 2019), (UNE-EN ISO 14064-2 2019), (UNE-EN ISO 14064-3 2019)*.

The calculation of GHGs is carried out in two stages *(UNE-ISO / TR 14069 2015);* the first stage consists of converting activity data into GHG emissions: GHG emissions or removals = activity data x emission or removal factor. The second stage considers the Global Warming Potential (GWP) of each GHG and allows calculating the conservation of GHG emissions or removals in the climate impact, identified in tons of CO2 equivalent (tCO2-e):

$$\text{GHG emissions} = \sum_{\text{gas}} \text{emissions} \times \text{PCG}_{\text{gas}}$$

Calculation of GHG emissions; Definition of the symbols: GHG, CO2 equivalent: Σ, sum of gas emissions; PCG, to the potential of global warming. *(UNE-ISO / TR 14069 2015).* Equation (1). Source: *(UNE-ISO / TR 14069 2015).*

The basis for calculating carbon emissions in a building material is defined from the sum of the GHGs provided by the chemical components that make up a material; within the EPD(s) and *(ISO, I. 14020 2000)*, in many cases the content of the sum of GHGs can be seen, data that as a whole will be understood as CO2 emissions and that are indicated according to the ISO *(EN ISO 14025 2010)* and the standard UNE-EN *(UNE-EN 15804 2012),* in which the current foundations are determined, both for the calculation of the life cycle inventory and for the life cycle impact evaluated of an EPD, being verified and validated in the European Unión.

A product is defined as a good or service, or a group of goods or services in relation to the life cycle of the product in which the environmental aspect implies activities, with environmental impact *(EN ISO 14025 2010)*. According to *(EN ISO 14025 2010)* an environmental declaration (type III) -EPD the production of a product implies the acquisition of the raw material, the Industrialization, the use, the end of the useful life (life cycle).

According to the standards *(UNE-EN 15804 2012), (UNE-EN 15804 2012+ A1 2014)*, the stages and modules included in the life cycle are: 6.2.2, A1-A3: Product stage, modules and information, 6.2.3, A4-A5: Stage in process, construction, modules and information, 6.2.4, B1-B5: Stage and use, information modules referring to the building structure, 6.2. 5, B6-B7: Stage of use, modules and information concerning the operation of the building, 6.2.6, C1-C4: End of life stage, information module, 6.2.7, D: Benefits and burdens occurring after the limits of the material's use (potential for reuse, recovery). These described stages are part of the content of an EPD *(ISO, I. 14020 2000)* and constitute the data of embodied carbon in the materials.

The Building Services Research and Information Association- BRISA, indicates that in order to calculate the embodied carbon in the building, it is necessary to: a- Identify the type of material to be used in a project or design, b- establish the amount of materials to be used , c- make use of the Carbon and Energy Inventory, developed by the University of Bath, UK, d- Multiply each weight of each material by the CO2 emission factor, obtaining the CO2 emissions of each material that has been used in the building, e- finally add up all the CO2 emissions obtained from each material used to see the total impact of the embodied carbon. *(BRSRIA Measuring embedded carbon - the next indicator of sustainability, consulted on August 10, 2020, https://www.bsria.com/)*.

In the research presented in this article, an evolution in the procedure for calculating embodied carbon is demonstrated, as more accurate CO2 data is used in this case: a-Identify the data of the declared functional unit of the material according to the EPD based on the European Union standards *(UNE-EN 15804 2012), (EN ISO 14025 2010),* b-Identify the area in m2 of the surface to be intervened with the material(s) to be used, c-Multiply the data provided by the GWP in the EPD, of the CO2 emissions declared in each material by the surface in m2 to intervene, d- Add up the emissions obtained by each material to be used to define the total carbon embodied in the proposed building or design.

A1-A2 kg CO2 equiv/UF x A.m2 = kg CO2 equiv/UF

Calculation of Embodied Carbon (materials for architectural design); Definition of the symbols: A1-A2: modules (data in EPD), Finished product stage. 2. METHODOLOGY (DESCRIPTION)

2.1. Criteria for compiling CO2 emission data according to DAP(s), UNE, ISO standards

According to the Catalogue of building solutions *(Construction Database 2019)*, of the Catalogue of constructive retrofitting solutions of the Valencia Institute of Building and the classification of products and materials, depending on the properties of thermal insulators for energy retrofitting IVE- Generalitat Valenciana *(P1 Products and Materials: Properties of thermal insulators for energy retrofitting 2014)*, (Serrano, García, Ortega 2011), the following materials have been classified: Mineral wool (MW) - rock wool (SW) of mineral origin, Mineral wool (MW) - glass wool (GW) of mineral origin, Expanded polystyrene (EPS) of synthetic origin, Extruded polystyrene (XPS) of synthetic origin, Polyurethane or Polyisocyanurat or (PUR) of synthetic origin, Expanded Perlite (EPB) of mineral origin, Cellular glass (CG) of mineral origin, Sheep wool (SHW) of animal origin, Cotton (CO) of plant origin, Hemp (HM) of plant origin, Cellulose (CL) of plant origin, Cork (ICB) of plant origin, Coconut fiber (CF) of plant origin, Flax (FLX) of plant origin, Wood fibers (WF) of plant origin.

From the Catalogue of building solutions *(Construction Database 2019)*, the equivalent materials in the construction market were studied, in relation to building products or materials with environmental declarations of EPD product(s), environmental self-declarations, material data sheets according to the producing company; also analyzed data from the Eduardo Torroja Institute of Construction Sciences (IETCC), *(Opendap 2013)*, all according to the standards *(EN ISO 14025 2010), (UNE-EN 15804 2012), (UNE-EN 15804 2012+ A1 2014)*.

The analysis of the data was based on the content of the Environmental Product Declarations -EPD(s), taking into account the data of the global warming potential GWP [kg CO2 eq], and the calculations of the greenhouse gas emissions -GHG, related to the definition of CO2 according to the time horizon of 100 years by the IPCC, Table. A.1 *(IPCC guidelines for national greenhouse gas inventories: reporting instructions 1997),* and the updated data in the ISO 14067 *(UNE-CEN ISO / TS 14067 2015)* replaced in 2019 *(UNE-EN ISO 14067 2019)*.

The process and criteria of the study are described in Table 1; the objective of the analysis of the EPD information was to establish a macro-criteria of information selection to compile the GWP emission data [kg CO2 eq], in the materials indicated in the construction database *(Construction Database 2019).* The content to be evaluated and compiled after the classification of the data was: Product stage: A1-A3, Construction process: A4, A5, Use stage: B1-B7, End of life stage: C1-C4, and reuse: D, indicated in the information, of the EPD according to the standards *(ISO, I. 14020 2000), (UNE-EN 15804 2012+ A1 2014)*.

Table 2 shows two cases of materials with information on CO2 emissions, according to the parameters of the stages (A1-A5, B1- B7, C1- C4, D); the data were compiled after being classified and evaluated. Case 1: mineral wool (MW); case 2: glass wool (GW).

Table 2 shows two cases of materials: Mineral wool (MW) - rock wool (SW) of ROCKWOOL *(Thermal Insulation of Rock Wool for Buildings 2015)* and Mineral wool (MW) - glass wool (GW), from Isover saint gobain *(ECOVENT 35 2017)*; the EPD information of each material - product, in this case of thermal insulators, identifies the CO2 emission values to be compiled in the Construction Database *(Construction Database 2019)* of the Catalogue of constructive retrofitting solutions of the Valencia Institute of Building.

Graph 1 identifies the analysis performed in the Catalogue of building solutions of the Construction Database of the Valencia Institute of Building-IVE *(Construction Database 2019),* after entering the data of the compilation according to the EPD(s) of the products. From a total of 829 materials, the data of GHG emissions (kg CO2 eq) were introduced, in 214 materials that complied with EPD(s) and the standards *(EN ISO 14025 2010), (UNE-EN 15804 2012+ A1 2014)*; of the total of 829 materials studied, no specific emission data was found in some 615, due to Lambda (Λ λ) and the specificity of the material, it was not always possible to find data to compile the information to the catalogue, although this does not rule out the relationship of emissions, with the denominations or origins of some others materials.

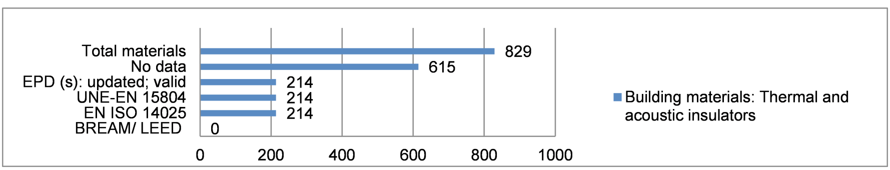
Table 2. Detailed value, according to the Environmental product declaration –EPD, and the Global warming potential -GWP [kg CO2 eq] - Products: ROCKWOOL, Isover, saint gobain. Source: (own elaboration)

Graph 1 shows that the information of the environmental statements of product(s) EPD, were decisive because they are data developed based on compliance with ISO(s) and standards *(EN ISO 14025 2010), (UNE -EN 15804 2012+ A1 2014)*, in this case the regulatory compliance of the European community in terms of environmental product declarations, was the determining aspect to find data to qualify and proceed to compile the information.

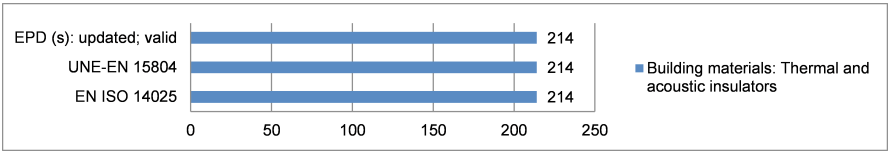
Graph 2 identifies that of the total data analyzed for 829 materials in the catalogue of the Construction Database, of the Valencia Institute of Building-IVE *(Construction Database 2019)*, about 214 comply with the standards *(EN ISO 14025 2010), (UNE-EN 15804 2012+ A1 2014)*. This information was evaluated with the aim of indexing the data to the database *(Construction Database 2019)*, following a criterion of qualification of the information according to the fulfillment of the 3 Points evaluated.

2.2. Qualification according to the macro-criteria for the compilation of CO2 emission data

Graph 3 identifies the 3 qualification criteria, which allowed establishing the classification of the data information in the macro compilation criterion applied to the rest of the 829 materials; the qualification was based on the data of the EPD(s) of the consulted materials, the material designation and the origin in relation to the materials in the catalogue *(Construction Database 2019)*. The macro criteria for the compilation of the emission data was: comply with 1- Environmental Product Declaration- EPD according to: Standard *(UNE-EN 15804 2012+ A1 2014)*, 2- Environmental Product Declaration - EPD according to: ISO *(EN ISO 14025 2010)*, 3- Environmental product declaration - EPD, according to: EPD (s) with the most up-to-date information.



Graph 1. Data to be compiled in the database (Construction database 2019), of the Valencia Institute of Building - IVE, according to the EPD(S), and the standards (EN ISO 14025 2010), (UNE-EN 15804 2012+ A1 2014). Source: (own elaboration)

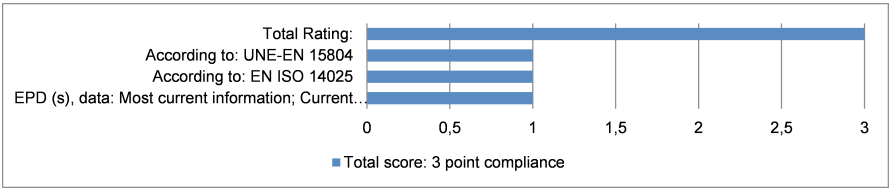


Graph 2. Useful CO2 emissions data for compilation in the database (Construction Database 2019), according to EPD(S). Source: (own elaboration)

By complying with a 3-point rating, the data to be compiled has provided information on the CO2 emissions according to: a-global warming potential (GWP) [kg CO2 eq], environmental impact *parameters (Summary for Policymakers and Technical Summary of Working Group I Report 1995)*, b- EPD according to standard(s), and ISO(s) according to standards *(AENOR, search for 2020 standards),* c-public data, for Spain with information according to standards *(UNE-EN 15804 2012+ A1 2014),* useful information from other data sources, e.g. Eduardo Torroja Institute of Construction Sciences-Spain *(Opendap 2013),* d- EPD from the public website - international information (other media), e - EPD(s) verified with current European Union standards *(AENOR, 2020 standards search),* f- EPD independent data from: BREEAM / LEED / VERDE, g- data supplemented with self-declarations of environmental products.

3. RESULTS

The 3 points obtained in 214 cases of compiled materials, implies that the information on the emissions of the materials comply with the regulations *(UNE-EN 15804 2012+ A1 2014), (EN ISO 14025 2010),* and valid information. In 15% there were two or more EPD(s) to compare from which emission data compiled only obtained the 3-points, for the other cases there was only one EPD source that in turn met the 3 points. In other cases the only information about the CO2 emission data of a material was based on the web data *(Opendap 2013)* according to the standards *(UNE-EN 15804 2012+ A1 2014), (EN ISO 14025 2010)*.
The evaluation of the 3 points qualified was of the following scale: 0.00 to <2.00 (Not useful); 3.00 (Useful), being the qualification (useful), the one of importance for the compilation. This procedure established the selection criteria for the data to be compiled in the database (Construction Database 2019), see the example in Table 3. From the sample of 15 cases of materials, taken based on the



Graph 3. Criteria for data qualification, for compilation to the database (Construction database 2019), (P1 Products and Materials: Properties of thermal insulators for energy rehabilitation 2014). Source: (own elaboration)

information of the EPD according to (ISO, I. 14020 2000) are useful for compiling 14 data from 15 samples, obtaining in these 14 samples the three points.

3.1. Tested hypotheses, criteria for data compilation

Table 3 shows the compilation criteria before including any type of emission data [kg CO2-eq.]. At this stage it was proposed to compare the qualifications obtained among 4 cases of the same type of Rock Wool material, according to the content of 4 EPD(s) case1: *(Acustilaine 70 2013),* case 2: *(Thermal Insulation of Rock Wool for Buildings 2015),* case 3 *(DP-3 Multipurpose Rock Mineral Wool insulation, Knauf Insulation, doo, Skofja Loka 2013)*, case 4 (Rock Mineral Wool Insulation 33 - 45 kg / cu.m 2016) all with market emission data; where the second case of rock wool (SW), went on to have a rating of 3 points, since it obtained the maximum value in each of the criteria evaluated, obtaining the values assigned on the use of *(UNE-EN 15804 2012+ A1 2014)*: 1.00 (point), *(EN ISO 14025 2010)*: 1.00 (point), and EPD, with data on current dates: 1.00 (point); 3 points.
The materials in which it is not possible to find a minimum of 4 EPD(s) to compare them, because they are materials with few data in the market and whose rating in one or two EPD is 3.00 (Useful), which is useful information for the catalog; all cases with ratings> 2.00 (> 3.00) are doubtful.

3.2. Tested hypotheses, classification, and qualification of data usefulness

Table 4 explains the data classification ratings: 0.00 to <2.00 points (Not useful); 3.00 points (Useful); where most of the samples based on EPD(s), obtained useful scores (3 points), i.e. CO2 emissions data are useful for the Database, from the Valencia Institute of Building-IVE *(Database of construction 2019)*. Of the 15 samples, only one case (without data) had a data rating: 0.00 to <2.00 (Not useful).
The demonstration of the usefulness of the qualified data of emissions, with 3 points obtained (compiled in the IVE catalog), applying Equation (2) (A1-A2 kg CO2 equiv/ UF x A.m2 = kg CO2 equiv/UF), in the case of 2 materials in an example of retrofitting of a façade of 83 m2, demonstrated the importance of using CO2 qualified data to calculate the embodied carbon of a building. Case of 2 materials compared: A- Expanded polystyrene (EPS) of synthetic origin: A1-A3: 9,76E+00kg *(GlobalEPD-RCP-007 2018),* (table 4). Apply the material in the retrofitting of the façade: build 83 m2 of facade surface to intervene. 9,76E+00kg x 83 m2= 810, 08 CO2 equiv/UF in façade. B-Mineral wool (MW): A1/ A2/A3: 2.1E+00 *(ECOVENT 35 2017)*, (table

	Qualification for compilation of emission data of [kg CO2-Eq.] (catalog of materials of the Valencian Institute of Building - IVE) according to the content of the "Environmental Product Declaration" -EPD							
	Material designation	Origin	Material Name in the market	EPD according to: EN ISO 14025 (European Union)	EPD according to: Standard, UNE-EN 15804 (European Union)	EPD, data: effective dates	Sum of qualification: utility of emission data, for compilation in catalog IVE: 0.00 to <2.00 (Not useful); > 3.00 (Useful)	Highest Rating: Index to the catalog of materials of the Valencian Institute of Building - IVE
Case 1	Mineral wool (MW) - rock wool (SW)	Mineral	Rigid rock wool panel ISOVER, non hydrophilic, uncoated (0.034 W / (m · K))	1,00	1,00	0,00	2,00

Case 3	Mineral wool (MW) - rock wool (SW)	Mineral	Multipurpose rock mineral wool insulation (0.039 W / (mK))	1,00	1,00	0,00	2,00	
Case 4	Mineral wool (MW) - rock wool (SW)	Mineral	Insulation of mineral rock wool 33 - 45 kg / cu.m (0.035 - 0.037 W / mK)	1,00	1,00	0,00	2,00	
				EVALUATION CRITERIA	EVALUATION CRITERIA	EVALUATION CRITERIA		

Table 3. Comparison of ratings after evaluating the content of 4 EPD(s), case: Mineral wool (MW) - rock wool (SW), according to the grade obtained 3.00 points (Useful); based on the indexation of CO2 emissions data to the database (Construction database 2019) Valencia Institute of Building - IVE. Source: (own elaboration)

4). Apply the material in the retrofitting of the façade: build 83 m2 of facade surface to intervene. 2.1E+00 kg x 83 m2= 174, 3 CO2 equiv/UF.
A- Expanded polystyrene (EPS)= 810, 08 CO2 equiv/UF of Embodied Carbon in façade; B-Mineral wool (MW)= 174, 3 CO2 equiv/UF of Embodied Carbon in façade. In case of using both materials (EPS and MW) in the façade, the total of Embodied Carbon is: 984, 38 equiv/UF. It includes Stages A1-A3 of the EPD(s) including the transport. The calculations in the cases A and B show the importance of the qualified data.

CONCLUSION

The macro-criteria for the compilation of CO2 emissions data proposed in this research, for the database *(Construction Database 2019)*, are defined in the classification and qualification of the information of the EPD(s), the technical sheets, the investigations, according to the data of GHG emissions, based on the standards and ISO(s), *(EN ISO 14025 2010), (UNE-EN 15804 2012+ A1 2014)*. The current European Union regulations on GHG emissions include global warming potentials (GWP) as a function of CO2 over the 100-year, IPCC *(2006 IIPCC guidelines for national inventories of greenhouse gases, IIPCC 2006)*.
The contents that most contribute to a process of compiling emissions data of the global warming potential GWP [kg CO2 eq], are: Product stage: A1-A3 (including transport),

Qualification based in data of GHG emissions (15 cases of thermal materials)

Bullet point list	Material name	Material name in data source	STAGE A1- A3, GWP [kg CO2 eq]	Qualification
1	**Mineral wool (MW)**	rock wool (SW) of mineral origin, rock wool ROCKWOOL (37 mm; density of 30 kg / m3) *(Thermal Insulation of Rock Wool for Buildings 2015)*	A1-A3: 1.2E+00	**rating: 3 (Useful)**
2	**Mineral wool (MW)**	glass wool (GW) of mineral origin (Air chamber factory facade (Glass Wool, 35 mm) Isover- insulators) *(ECOVENT 35 2017)*	A1A2/A3: 2.1E+00	**rating: 3 (Useful)**
3	**Expanded polystyrene (EPS) of synthetic origin**	Stabilized expanded polystyrene insulator (EPS) <0.065 W/ m • K (Traditerm System)*(GlobalEPD-RCP-007 2018)*	A1-A3: 9,76E+00	**rating: 3 (Useful)**
4	**Extruded polystyrene (XPS) of synthetic origin**	Extruded Polystyrene Foam (thickness 5 cm) *(Extruded Polystyrene Foam Thermal Insulation Sheet XPS -DANOPREN 2016)*	3,98E+00	**rating: 3 (Useful)**
5	**Polyurethane or Polyisocyanurat or (PUR) of synthetic origin**	Thermal insulated projected polyurethane foam (projected polyisocyanurate) *(Thermal insulated projected polyurethane foam, closed cells; density 40 kg / m3 2014)*	A1-A3: 15.6	**rating: 3 (Useful)**
6	**Expanded Perlite (EPB) of mineral origin**	Expanded Perlite *(" Databases: Building", Opendap, accessed May 1, 2019, https://www.opendap.es/)*	A1-A3: 0,14	**rating: 3 (Useful)**
7	**Cellular glass (CG) of mineral origin)**	Cellular glass *(FOAMGLAS® T4 +2014)*	A1-A3: 1.3E+0	**rating: 3 (Useful)**
8	**Sheep wool (SHW) of animal origin**	Sheep wool *(" Databases: Building", Opendap, accessed May 1, 2019, https://www.opendap.es/)*	A1-A3: 5,53	**rating: 3 (Useful)**
9	**Cotton (Insulating, not hydrophilic)**	Cotton *(" Databases: Building", Opendap, accessed May 1, 2019, https://www.opendap.es/)*	A1-A3: 5,53	**rating: 3 (Useful)**
10	**Hemp (Aislatne, not hydrophilic)**	Aislatne, not hydrophilic *(" Databases: Building", Opendap, accessed May 1, 2019, https://www.opendap.es/)*	A1-A3: 17	**rating: 3 (Useful)**
11	**Cellulose (CL) of vegetable origin**	Cellulose (Cl) cellulose insulator- AislaNat *(Loose fill cellulose insulation 2018)*	A1 7,15E-02 / A2 2,10E-02 / A3: 6,49E-02	**rating: 3 (Useful)**
12	**Cork (Wood, compressed)**	Wood, compressed *(" Databases: Building", Opendap, accessed May 1, 2019, https://www.opendap.es/)*	A1-A3: 1.1	**rating: 3 (Useful)**
13	**Coconut Fiber**	Coconut Fiber *(Carabaño, Bedoya, Ruiz 2014)*	no data	**rating: no data (Not useful)**
14	**Linen (FLX) of plant origin**	Flax fiber *(" Databases: Building", Opendap, accessed May 1, 2019, https://www.opendap.es/)*	A1-A3: 17	**rating: 3 (Useful)**
15	**Wood chips (WF) of vegetable origin**	Fiber: Wood, M DF Melamine *(Medium density fibreboard (MDF), both raw as well as melamine faced medium density fibreboards 2017)*	A1-A3: 0,74	**rating 3 (Useful)**

Table 4. Data-based qualification (EPD) of GHG emissions, in 15 cases of thermal materials. Source: (own elaboration)

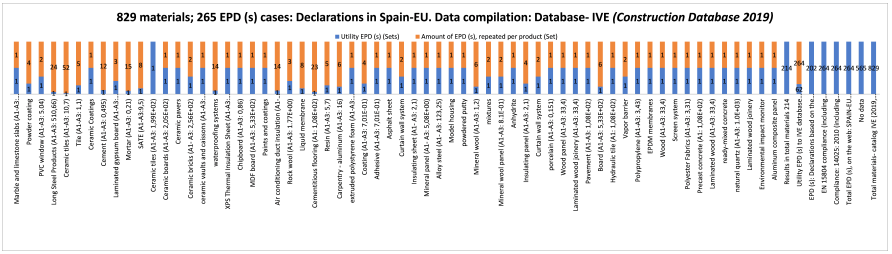

Table 5. Table with 214 materials that have reached 3 points; including data of equivalent CO2 emissions, according to qualified data of the EPD(s), according to the regulation. Source: (own elaboration)

Construction process: A4, A5, Use stage: B1-B7, End-of-life stage: C1-C4, D: reuse, according to the EPD(s), with stage A1-A3 being the one with the most information as it is mandatory.

The macro-criteria used in this research defines a logical procedure for the usefulness of the CO2 emissions data, when compiling the information for the Construction Database, of the Valencia Institute of Building-IVE *(Construction Database 2019)*. From the sample of 829 materials indicated in the catalogue database, about 214 materials whit EPD(s) have been found in the market, which mainly comply with the standards *(EN ISO 14025 2010), (UNE-EN 15804 2012+ A1 2014),* according to the calculation procedures of CO2 emissions established in the European Union standards.

Table 5 identifies a summary with 214 materials with useful data for the materials catalogue, including data on CO2 emissions, according to the EPD regulations. 264 materials include EPD data for repeated materials. Of the 829 materials in the catalogue *(Construction Database 2019)*, no emission data was found according to EM 565 regulations. The usefulness of GHG emissions data in the life cycle of 214 materials for compilation in the construction base *(Construction Database 2019)*, identifies the current status of materials in the building products industry in Spain and its relationship with technological innovation and environmental impact analysis, the choice of materials in the construction of sustainable designs in Spain and the European Union, can be justified in the comparison of CO2 emissions.

The usefulness of the data of the emissions in the EPD(s), is related to the total of the life cycle stages, calculating the emissions for each of the material stages (Product stage: A1-A3, Construction process: A4, A5, Use stage : B1-B7, End-of-life stage: C1-C4, D: reuse; this allows to identify the impact of the embodied carbon from the use of a material in a building, to the possibility of reusing the material; The calculation method for each stage can be carried out with equation (2), which allows to calculate the impact of the emissions even at the time of reuse of the material at the end of the life cycle.

PAPER #5.09

MASS TIMBER CONSTRUCTION FOR MULTI-FAMILY URBAN HOUSING: CARBON12 AND THE CANYONS

Edward Becker[a], Kevin Lee[b]
[a]Virginia Tech, Blacksburg, Virginia
[b]StudioMB, Washington D.C.

ABSTRACT

By the year 2050, an additional 2.5 billion people are expected to inhabit urban areas. In addition, cities across the globe face the challenge of aging housing stocks coupled with the necessity to decrease carbon emissions from building construction and use. Such challenges suggest that data-driven design solutions that prioritize fast and efficient construction with sustainably harvested, low-carbon materials such as cross-laminated timber (CLT), a mass timber product, may be best suited to address the housing needs engendered by the aforementioned macro factors. Considering that CLT construction is nascent in many regions of the world other than some timber-dominant countries in the European Union, this document explores how effective information exchange among project constituencies can help CLT-based mass timber projects overcome the unique barriers to construction that exist in regions without well-established mass timber industries, the United States being of particular focus. Two innovative case study projects, Carbon12 (2018) and The Canyons (2020), are unpacked by the authors in regard to both analog and digital information transfer. Both multi-family housing projects were designed and developed by Kaiser+Path in Portland, Oregon and are two of the first examples of high-rise, multi-family mass timber construction with CLT in the United States. The authors draw upon first-hand CLT design experience with one author being an architectural designer for Kaiser+Path's The Canyons. A primary conclusion of this case study document suggests that a close integration between project team members early in the design process is critical to successful project completion. The authors also highlight specific design-to-construction situations where more advanced digital workflows could be particularly beneficial. Based upon the authors' knowledge, this is the first peer-reviewed case study publication to document either building.

KEYWORDS

Low-carbon construction; multi-family housing; cross-laminated timber.

INTRODUCTION

Low-carbon construction technologies including cross-laminated timber (CLT), a mass timber product, have proven to lower carbon emissions from construction and lower construction costs while increasing construction speed and construction site safety in Europe and Australia where a majority of CLT-based buildings have been built (Mayo 2015). Underpinning each of the aforementioned CLT-related construction benefits are integrated workflows, or data flows, that allow project teams to collectively coordinate nearly every aspect of the design-to-construction process. Data-driven design solutions that prioritize fast and efficient construction with low-carbon materials like CLT may provide a solution for the architecture, engineering, and construction (AEC) industries over the coming decades

as they attempt to overcome the inverse, "wicked," challenge of significant urban growth and provision of housing on one hand, and the need to lower greenhouse gas emissions from construction on the other (Boyer Cook 2013). Despite the recognized benefits of mass timber construction in the AEC fields, only a few European countries have mass timber industries that are well-developed enough to facilitate fast, efficient construction of low-carbon multi-family urban housing on a large scale. For many other countries globally including the United States, the infancy of the mass timber industry - including the relatively slow adoption of building codes that permit high-rise mass timber buildings - hinders overall construction efficacy.

This case study research provides a roadmap for AEC professionals regarding two of the first large-scale, CLT, multi-family housing projects developed in the United States: Carbon12 and The Canyons. Carbon12 was completed in 2018, becoming the tallest CLT building in the United States, whereas The Canyons is scheduled to complete construction in Summer 2020. Located in Northeast Portland, Oregon, both projects were designed and developed by Kaiser+Path, a Portland-based company composed of Kaiser Development, Inc. and PATH Architecture, Inc. Similar to other CLT-based mass timber projects in the United States and in countries around the globe with nascent mass timber industries, the projects faced a number of unique process barriers due to the novelty of CLT use among project constituencies and the size of the projects for which the material system was employed. Such barriers challenged the Kaiser+Path project team, and despite the successful completion of Carbon12 and the expected successful completion of The Canyons, could, if improperly handled by a project team, lead to undesirable project results or cancelled projects.

Carbon12 and The Canyons are uniquely innovative in the context of American housing and employ construction methods not found in other buildings of similar type and scale. As such, this case study document provides novel intellectual content to the AEC industries as the projects have not been the subject of peer-reviewed documentation previously. This case study document of Carbon12 and The Canyons will begin with a background description of the global macro factors that have engendered the mass timber movement with CLT. The background description frames two primary challenges to the city of the future, the ability to provide enough equitable housing and the ability to provide that housing in a low-carbon manner. Using Carbon12 and The Canyons as examples for high-quality, innovative construction technologies/practices - quick to build with low-embodied carbon - the case study then focuses on the barriers to CLT construction in regions of the world like the United States with nascent mass timber construction industries. Barriers to successful project completion include the difficulty to accurately cost estimate a project under evolving financing conditions, the difficulty to achieve code compliance when local jurisdictions are unfamiliar with mass timber construction, and the difficulty to coordinate construction when few of the project constituencies have experience with mass timber products and the related logistical demands they entail.

Through a particular focus on the aforementioned project barriers, each of which relate to data management and interchange, the authors seek to provide a resource for related CLT-based projects in urban areas globally as a means to support the increased provision of mass timber housing and the successful completion of buildings with low embodied carbon. The innovative building technologies and practices explored in the following sections

are relevant due to their ability to enhance urban quality of life and urban social and environmental sustainability through high-quality, high-tech construction.

1. INTELLECTUAL CONTEXT

1.1. Case study background

According to research from the European Commission, the world's urban population is expected to nearly double by year 2050 from the 4.2 billion people in cities in 2018. "By 2100, some 85% of the population will live in cities, with urban population increasing from under 1 billion in 1950 to 9 billion by 2100" (European Commission, n.d.). To support urban population growth globally and the related provision of adequate housing in cities by 2025, construction spending alone is expected to cost $9-$11 trillion (Woetzel et al 2014). In the United States, "the baseline demand for new housing units between 2015 and 2025 will range from 16.0 to 18.2 million units" as a short-term forecast (McCue 2017). A vast majority of these homes are expected to be built in urbanized areas.

Inversely, the building sector must significantly reduce greenhouse gas emissions from building construction and operation to align with the climate goals set forth by a number of leading global organizations including the World Green Building Council and the United Nations. It is widely recognized in the architecture, engineering, and construction (AEC) industries that lowering the embodied carbon in building materials is one of the key avenues to achieve global climate goals. As embodied carbon in building materials accounts for 28% of total greenhouse emissions from construction globally, the utilization of low-carbon or carbon-negative building materials can be particularly significant for lowering total expenditure (Cramer 2020).

Wood is widely recognized for its carbon sequestration benefits and its potential to assist in the lowering of embodied carbon in construction. As such, global demand for wood products is expected to double in the next 15 years and global wood industries

Figure 1. Mass Timber Code (IBC 2021). Source: (Atelier Jones, LLC n.d.). "CLT is a large-scale, prefabricated, solid engineered wood panel. Lightweight yet very strong, with superior acoustic, fire, seismic, and thermal performance, CLT is also fast and easy to install, generating almost no waste onsite. CLT offers design flexibility and low environmental impacts" (APA 2018).

are experiencing the highest growth since the 2008 economic crash (Laguarda-Mallo Espinoza 2018). In the United States, the increased demand is coupled with changing building codes, sustainable forest management policies, and the expanding demand for low-carbon construction solutions. The increased demand for wood is largely in opposition to concerns over global deforestation, only recently in decline due to emerging forest management practices such as FSC certification in the United States. Additionally, the International Building Code recently adopted new terminology and height protocols for heavy timber material use after an internal committee focused on tall wood buildings conducted over two years of extensive interdisciplinary debate, research, and testing including, but not limited to, structural studies and fire performance testing. Although the new Type IV codes (Fig. 1) have yet to be fully implemented within individual American states, such legislative adjustments present new opportunities for the utilization of technologically advanced wood products such as cross-laminated timber (CLT).

CLT in combination with other mass timber technologies has been heralded as the first new way to build skyscrapers and related multi-story construction in over 100 years. Despite the expanded use of cross-laminated timber (CLT) for structural applications, timber-dominant countries in the European Union are the only countries globally with matured mass timber markets/industries. For much of the rest of the world, CLT is a nascent technology. The infancy of mass timber markets/industries in many countries, including the United States, injects certain use barriers to mass timber construction that may limit the potential for such low-carbon construction solutions to be used on a large scale in response to housing needs for increasing urban populations. Thus, a key objective for AEC professionals with successful CLT-based design and construction experience should be to disseminate knowledge to lower such use barriers for future projects. The following two case study projects are a direct attempt to disseminate such knowledge as it pertains to the information exchange or "dataflows" found within the two projects' design-to-construction processes.

1.2. Novelty of case study buildings in non-European contexts

Carbon12 is the first - and tallest - CLT-based mass timber structure to be built in the United States. It is also the only high-rise residential building to be permitted and completed in the U.S. The Canyons is a furtherance of the mass timber construction ideas and processes developed for Carbon12. It is the first and only CLT project in the U.S. to use a hybrid, light timber frame and CLT structural construction system. Both projects provide novel information for the subject area of this study. Brock Commons is the only related non-European CLT-based high rise project globally. It was permitted and built in Canada with construction completing in 2017.

2. METHODOLOGY

As presented in the forthcoming sections, the extracted information from both case study projects is drawn from the authors' first-hand experiences with mass timber construction in both Europe and the United States, as well as relevant project references. One author of the paper was an Architectural Designer for Kaiser+Path who was intimately involved in the design development, permitting, and construction administration process for The Canyons. The author also has experienced-based knowledge of Carbon12 through the direct exchange of project insight from colleagues who designed Carbon12 – e.g., the project owner, architects, and builders who sought to facilitate a dissemination

of mass timber education as well as to further prepare the author for their design/construction role within The Canyons project. All case study information was acquired through first-hand experience with the project team and on the project site unless otherwise noted. This information was also corroborated with multiple project team members for the writing of this document. The authors' objective to provide uncompromised information directly from the source and the lack of available project-specific data elsewhere about The Canyons are both rationales for using the direct-knowledge, experienced-based approach for this document.

3. EXTRACTED INFORMATION FROM CASE STUDY PROJECTS

3.1. Carbon12

At the time of this writing, Carbon12 is the tallest mass timber building in the United States. The eight-story urban multi-family housing project was completed in 2018 in Portland, Oregon and was designed and built by Kaiser+Path: an integrated design, development, construction firm led by Owner and Principal Benjamin Kaiser (Fig. 2, 3). Carbon12 set multiple key benchmarks for high-rise, multi-family mass timber construction in the United States. As stated by Kaiser+Path, the firm "set a new standard for what's possible in sustainable development in the United States … [by working] with city and state officials to waive restrictive codes limiting the height of wood buildings, making Carbon12 and future tall wood buildings in the US possible" (Kaiser+Path, n.d.). The 95-foot tall, 38,000 square foot building features a German-developed, mechanized underground parking system, first floor commercial space, and 14 multi-family residential units above. Structurally, the project utilizes a hybrid system composed of steel buckling restrained brace (BRB) frames paired with glulam columns and beams. Carbon12 uses "Douglas fir lumber in its columns, beams and the bottom layer of the exposed CLT" (Kaiser+Path, n.d.). The interior of the CLT panel uses spruce-pine-fir (SPF). The wood is sourced from British Columbia and uses wood killed by the Mountain Pine Beetle. Exemplifying the multifaceted

Figure 2. Carbon12 by Kaiser+Path. Source: (Kaiser+Path n.d.)

benefits of tall wood construction, the project overcame legal and logistical barriers to construction and provided new insight into the potential benefits of dataflow optimization to enhance future mass timber construction and project team coordination. The project also illustrates the importance CLT-related design teams should place on manufacturer engagement and coordination even within early design phases.

3.2. The Canyons

Following the successful completion of Carbon12, Kaiser+Path designed and developed The Canyons, a six-story, multi-family mixed-use project located directly adjacent to Carbon12 in Portland, Oregon (Fig. 3). The Canyons is a 65-foot tall, 110,000 square foot building that uniquely utilizes a combination structural system pairing lightframe timber bearing and shear walls with CLT floor panels. It has 70 market-rate residential units in the main building with a pedestrian alley, located on a North-South axis, that separates 11 micro-retail work-units from additional ground floor retail within the main building. Unlike Carbon12, Kaiser+Path collaborated with local builder R&H Construction as their general contractor while working directly with Catena Consulting Engineers to develop the structural strategy. Similar to Carbon12, Structurelam was the mass timber manufacturer/supplier and a critical project partner for both buildings. The Canyons is currently under construction with completion expected during Summer 2020. While the project is considered by Kaiser+Path to be a direct furtherance of Carbon12 regarding the pioneering of low-carbon construction techniques and methods in the United States, The Canyons' hybrid timber structural system, unique atrium design, and construction interfacing and logistic strategies are each unique to the project.

Both projects contain valuable process-knowledge for the AEC industry globally, particularly in regions of the world with nascent mass timber industries. The projects are presented in a back-and-forth manner over the following paragraphs with case-study knowledge being disseminated through the following two sections: (1) project funding and code compliance; and (2) project construction. The authors focus on specific instances in the design-to-construction process for both projects that are intended to provide the best use-value information for AEC professionals to positively influence future, urban, multi-family construction with CLT.

Figure 3. The Canyons by Kaiser+Path. Source: (Kaiser+Path n.d.)

3.3. Project funding

"As part of the Obama administration's commitment to mitigate climate change," the USDA launched the U.S. Tall Wood Building Prize Competition in 2014 (McKalip 2014). As engineering cost factors and code-related variances were deemed as key limitations to the expansion of tall wood construction in the US, the $2 million in USDA funds were targeted to specifically address both issues through the selection and subsequent financial support of winning projects. Having just independently developed, designed, and constructed a commercial mass timber

(glulam) project, Kaiser+Path shifted their focus and entered the competition with six weeks before the deadline. Due to their unique internal composition of "trained architects, contractors, and developers... [that also] already owned the proposed building site," they submitted a proposal for Carbon12 but were not ultimately selected (Kaiser+Path, n.d.)(Fig. 4). Despite the setback, the team decided to move forward with the design anyway. Kaiser+Path's office composition as owner/developer, architect, and general contractor will reappear throughout the case study as a key strategic advantage for successful project completion. In this case, the team was able to pivot financially and fund the project without USDA money, although there was a significantly smaller amount of US Forest Service Wood Innovation Grant money supporting engineering and permitting. The project's integrated, architect-as-developer funding model allowed greater flexibility with design and construction logistics than would otherwise be available if the project were reliant upon other funding means or an alternative team composition. This is one key reason the project was ultimately constructed successfully whereas other related projects by other offices were cancelled (Njus 2019). Throughout the project period, the team was able to adjust hard and soft project costs on-the-fly in coordination with the digital models and project affiliates. This was particularly important for a CLT-based project as the unique, hybrid structural system and novel wood use added additional complications to the standard methods of costing and construction. The ability to pivot design-wise to adapt to changing cost conditions and project constraints was time efficient in the small office where the owner/developer-architect-builder team consisted of approximately seven persons - depending upon the project stage - unlike related situations in larger, less-centralized companies. The project was planned as a condominium project with two ground floor commercial tenants and 14 potential residential owners. The high upfront project costs of using new CLT construction methods were able to be handled through the condo financing model. The premium price for high-end condo units in the up-and-coming Williams Avenue, Portland neighborhood was able to offset the uniquely high development costs for the project in terms of its special underground parking system and CLT expenses as compared to other non-CLT projects of a related size.

Figure 4. C12 Render 1, Tallwood Competition Proposal by Kaiser+Path. Source: (Kaiser+Path n.d.)

Kaiser+Path relied on the same architectural and general contracting Revit model for Carbon12 and separate Revit models for The Canyons. Structurelam, the mass timber supplier for both projects, produced a CLT package and project-specific glulam package that included handling and assembly notes, tolerance specifications, CLT panel data charts, and construction sheet sets in coordination with the general contractor. This information was not cohesively imbedded in a singular BIM model with linked data flows between project teams. As Carbon12 was the first project for which Kaiser+Path had utilized CLT at this scale of building, the project team held weekly meetings regularly to manage the complexity of design, construction, and CLT-specific material challenges. The project team was proactive and intentional in regard to predesign work

and coordination. For The Canyons, close coordination within the design development phase between architect, general contractor (GC), and mass timber supplier led to cost savings through the reduction of CLT panel thicknesses which then led to decreased concrete foundations.

3.4. Building code compliance

The challenge of building code compliance is one of the key factors that may impact design-to-cost decision making by CLT-related project teams. In world regions with less developed mass timber industries and relatedly less mass timber use, the work to overcome building code compliance challenges can cause significant financial problems due to project delays, unexpected fees, or further required research to gain approval by local governing bodies. The process for Carbon12 was no exception.

> Initially, the City of Portland required that Carbon12 go through an extensive third-party review process similar to a concrete building over 240 feet tall. The city had never reviewed a CLT project before, so it was clear that this route would take significant time and cost. However, at the state level, the Oregon Building Codes Division was launching a pilot program to establish a method for reviewing CLT buildings for local jurisdictions (Kaiser+Path, n.d.).

Ultimately, the city and state partnered on the review effort for Carbon12 after multiple city entities were consulted, and project data from Carbon12 was shared with the state to enhance its review process for future CLT buildings. The sharing of Carbon12's data with the state directly benefited The Canyons project by Kaiser+Path, which was designed a few years later, and it is likely to have lasting benefits for future CLT buildings even outside of Oregon's jurisdiction. This is not only due to the establishment of a baseline code review process for Oregon mass timber structures, but also due to the impact Carbon12 has had as a direct reference for the ICC Ad Hoc Committee on Tall Wood Buildings in their "review and approval of new building types to the 2021 International Building Code" (Kaiser+Path, n.d.).For both Carbon12 and The Canyons, challenges to overcome building code restrictions impacted the project timelines and had the potential to significantly disrupt cost estimates. The developer-architect-builder model at Kaiser+Path provided flexibility to overcome cost barriers and the small project team size helped to expedite project workflows. Each Kaiser+Path building also illustrates from a cost and code perspective how beneficial pilot-type buildings can be to pave the way for a further streamlining and optimization of related projects.

3.5. Project Construction

Above and beyond the required planning for a typical multi-family housing project, CLT-based mass timber projects require extensive pre-planning and project coordination. In regions of the world with nascent mass timber industries, the administrative hierarchy and coordination methods between the architect, general contractor (GC), and product manufacturers is particularly important to determine early in the process as working relationships and the division of labor may be different than in typical project delivery models. Additionally, the digital model, or building information model (BIM), may be developed and utilized differently than in standard - non-CLT - practice. For CLT-based projects, the tolerances between various building materials must be considered early in the design process and reflected in the method of BIM model development and utilization due to the high-level of mass timber precision from the factory, often 1/32 inch, as compared to steel and concrete which are considerably less precise.

The following paragraphs present specific aspects of the construction process for both Carbon12 and The Canyons. Through the following examples, tradeoffs are introduced between the utilization of integrated digital models for construction sequencing and coordination versus the less digitized methods of direct manufacturer interfacing and in-the-field construction workflow improvements. When novel material systems for construction such as CLT are adopted by the project team, key questions must be answered regarding the reliance on digital planning tools like BIM versus more traditional forms of project team communication, and at what point may more traditional methods of project team communication need to evolve into more advanced digitally-integrated workflows.

3.6. Carbon12: Material tolerance and coordination

If low-carbon construction using CLT-based mass timber elements is to provide a widespread, scalable solution for urban housing construction, the precision-based benefits of CLT's manufacturing process likely will need to be maximized, namely construction speed. As construction speed increases, project costs are lowered. Carbon12 was faced with a dual challenge, the need for construction speed to lower project costs on one hand and the inability to use CLT for the building's elevator cores on the other - a result of local seismic code limitations. As concrete construction for the building's structural core would have been schedule inhibiting due to time-intensive formwork construction and cure time, increased trade coordination on a limited site, and potential context-specific winter weather hindrances, the team chose to use a buckling restrained-braced (BRB) frame system. The steel-brace system was designed to work in conjunction with the CLT floor slab and glulam post-beam arrangement. The steel for the frame was sourced specifically for the project due to the engineers concerns that the typical steel-brace components were designed for much heavier types of the buildings (Forest Business Network 2018). The team also directly coordinated with Timberland, the framing subcontractor with an internal steel division, so that Timberland would directly fabricate and install the BRB system in conjunction with the timber package. Thus, the assembly of the entire structural system was optimized as a singular subcontractor would conduct not only 3D clash detection between the two material systems, but they would also facilitate efficient labor scheduling resulting from the same crew erecting the building's whole structure. The BRB frame system was constructed in three-story high increments so that the CLT could be threaded by a crane through the steel frame for fast assembly. After the CLT floors were completed to the required height, the next three stories of BRB framing were added. Uniquely, the CLT was prefinished in the factory by Structurlam which further enhanced the project's onsite construction schedule and proved be particularly critical through a historically wet and snowy Oregon winter. The factory-finished panels were directly lifted into place from arriving trucks, minimizing potential damage and staining while also eliminating the need for additional weather protection or finish work onsite. The factory pre-finishing by Structurlam is unique because it went beyond typical means of service for a mass timber company and required a significant amount of labor and space investment by the manufacturer. However, the intensive process directly facilitated onsite success as it not only minimized onsite panel labor but also allowed the construction team to continue structural assembly through inclement weather conditions without costly setbacks.

As new forms of advanced fabrication engender the creation of increasingly high-

precision building products such as CLT, a key concern for project teams is how to best coordinate the precision of such building systems with other project systems of significantly lower precision. The CLT elements for Carbon12 were significantly more precise than the steel frame and concrete foundation - the CLT precision being approximately 1/8" while acceptable tolerances for concrete could range from 1/2" to 1". As such, the project team coordinated with the structural engineer to fabricate steel 'buckets' (Fig. 5,6) that allowed the high-precision wooden elements to rest on the less-precise steel. The glulam beams were adjusted - trimmed to fit if necessary - to accommodate fluctuations in the steel and then bolted to the buckets to tie back to the primary steel structure.

This particular design solution is important to recognize for its key benefits to the construction coordination and assembly process. The project team recognized in advance that the steel, despite its factory fabrication, may not perfectly meet the wooden elements in the field due to factors such as creep, thermal expansion/contraction, and human assembly imprecision. Therefore, the intentional design of steel bucket joints allowed the element-to-element connections to be slightly adjusted on site. Such a process questions the utility of highly precise digital models that cannot simulate the human error or climatic factors that may influence material performance/accuracy on site. In this case, direct manufacturer interfacing regarding assembly logistics, detailed logistical planning for assembly, and in-the-field construction workflow improvements provided a streamlined construction process. For Kaiser+Path, extensive weekly pre-design meetings between the architect, builder, mass timber manufacturer, and framing subcontractor were necessary to coordinate the successful design, integration, and assembly of the BRB & CLT hybrid system of Carbon12.

Figure 5,6. Carbon12 Detail, Beam - Steel Core Connection with adjusted glulams. Source: (Kaiser+Path n.d.)

3.7. The Canyons: Construction speed and logistics

As a direct evolution of the ideas and processes that drove the design and construction of Carbon12, The Canyons was also designed with a CLT-based structural system. Construction speed and precision with low-carbon materials were each important drivers for the project team. Unlike Carbon12 that employed a hybrid mass timber and BRB-frame structural system, The Canyons is constructed of a unique combination of light-frame wood and CLT floor slabs. The hybrid wood assembly with light-frame structural walls - bearing and shear - and CLT floor slabs was chosen due to cost concerns and code-related obstacles. The concrete foundation, housing underground parking and topped with light-gauge metal framing for ground floor retail, is superimposed with light-frame timber walls and CLT floor panels from levels two through six. A multi-story exposed CLT atrium spanning nearly the entire length of the building, approximately 120 feet, and bisecting the main building mass down its North-South centerline, was a particularly challenging spatial element to permit and to construct. Excluding the exterior work-units, which are constructed with traditional building strategies, the project is in essence a double-loaded corridor arrangement with the timber corridor/atrium being an experiential focal point for the occupants.

As noted previously, integrated workflows between project team members that optimize on-site construction logistics are key to the success of fast-build, CLT-based mass timber construction systems. In response to this necessity, the multi-disciplinary project team spent a substantial amount of effort early in the project planning process to achieve a rapid construction timetable while also maintaining a comprehensive moisture mitigation plan. Unique to the project, the light-frame wood walls were originally designed to be prefabricated for fast, modular onsite installation. The team recognized from their experience on Carbon12 that the CLT assemblies could be constructed on site very quickly compared to other building systems. Thus, a clear challenge for the project team was to match the construction speed of CLT with that of the structural light-frame walls to keep the project on schedule, to minimize onsite CLT storage time, and to reach topout as fast as possible. The original intent was to have simple prefabricated walls, including wall frames and rough sheathing, "chase" or rapidly be constructed after CLT panel installation for assembly and schedule efficiencies. Assembly of the residential floors would occur sequentially beginning with the units east of the atrium after the atrium panels were completed. CLT panels would be installed from south-to-north on the east units with the prefabricated wood frames being craned into place immediately afterwards, just as CLT panels would begin to be installed simultaneously on the west units. Trade crews would then be coordinated to follow closely afterwards to create MEP penetrations, etc. in a fluid sequence.

However, during the design development project phase, the prefabricated nature of the light-frame wall elements were

Figure 7. The Canyons CLT and light frame integration. Source: (Marcus Kauffman, Oregon Dept. of Forestry n.d.)

changed due to project cost implications and means and methods complications. Without affecting the overall design intent or drawings, the construction strategy was shifted to traditional onsite timber framing, with the added consideration that light-frame studs would be precut for faster onsite assembly. This strategy facilitated faster assembly times than could be accomplished with traditional wood framing, but ultimately the light-frame wall construction method slowed the structure's overall construction speed as this framing strategy required an entire floor's wall assembly to be completed before the subsequent level of CLT could be craned into place (Fig. 7). As a result, onsite labor efficiency was significantly reduced and potential weather damage to stored and installed CLT panels onsite increased. An intensive amount of pre-construction coordination and review was also required by relevant parties due to the nature of pre-cutting the studs, similar to other types of prefabrication. In addition to a construction sequence plan for the structure, R&H had a predetermined internal strategy for panel shipment and laydown that they directly coordinated with Structurlam. Key project documents related to the CLT shipment and assembly included the following: (1) CLT shop drawings complete with handling instructions, panel identification, panel schedules, plan sheets, specifications, a tolerance listing, and a responsibility statement that included panel unloading guidance; and (2) elevation drawings of the shipment trucks loaded with panels and number coordinated to corresponding shops. The construction crew averaged approximately three days per floor for CLT assembly and six days per floor for light-frame wood construction. The project has already set a number of benchmarks for innovative wood construction (Fig. 8 and 9) in the United States and is on schedule for successful completion in Summer 2020.

In summary, the early coordination between Kaiser+Path, Structurelam, and the other project team members was highly desirable to develop a successful approach to panel fabrication and construction logistics. The Canyons was a direct furtherance of the design and construction intelligence utilized on Carbon12, yet was unique in a number of its challenges. The digital technology workflows for the project were defined less

Figure 8,9. The Canyons CLT and light frame integration. Source: (Marcus Kauffman, Oregon Dept. of Forestry n.d.)

by high-tech uses of simulation and analysis software, but rather the diversity of file types and multiple team members through which the information had to flow. An emphasis was placed on direct person-to-person coordination.

4. DISCUSSION

4.1. Opportunities for off-site fabrication and integration

Relative to The Canyon's prefabricated wall assemblies, the construction speed challenges that the project team experienced may be mitigated through higher-end workflows that pair Revit data with advanced robotic manufacturing. If the team continues to refine the hybrid-timber construction logistics and costs for advanced fabrication are managed, technologies such as the robot-based fabrication of timber-frame modules pioneered by the ETH's Gramazio Kohler Research Lab may be of particular utility (Gramazio Kohler, n.d.). Additionally, relative to factors that are unpredictable on site such as human construction error and weather, integrated cloud-based models across the project team that allow for construction changes to be quickly coordinated could be particularly useful. For example, with integrated digital tools, the construction team can use mixed-reality overlays, site scans, and shared digital models across the construction team to account for, and subsequently fix, construction inconsistencies.

4.2. Opportunities to enhance design-cost modeling

Based upon the authors' experiences designing mass timber buildings in Europe and the United States, including The Canyons, a further integration of cost and design models could be beneficial across the mass timber industry to help streamline the design-to-construction process, specifically after initial project bidding. The aforementioned lack of Revit model integration between the architects and contractors on The Canyons presents an opportunity to link decision making with real-time design-to-cost updates. After initial project bidding is typically completed and the general contractor and primary subcontracting teams have been selected, BIM design data could be linked to cost calculations in real-time for major project components. Such a linking of information is uniquely relevant to large prefabricated buildings like The Canyons due to the extreme degree of pre-project coordination necessary. Architectural offices have shown an interest in such streamlining through projects such as Model-C by Generate and B2 by SHoP.

CONCLUSION

Effective information exchange among project constituencies can help CLT-based mass timber projects overcome the unique barriers to construction that exist in regions of the world without well-established mass timber industries. Additionally, a close integration between project team members early in the design process is critical to successful project completion in such contexts. Both Carbon12 and The Canyons have overcome design, permitting, and construction barriers, many of which stem from the lack of experience with CLT construction in the United States and the general infancy of the mass timber construction industry at a global scale. If urban populations increase globally as projected, case study projects such as Carbon12 and The Canyons can provide valuable information for AEC professionals in support of the widespread construction of new, low-carbon, multi-family urban housing.

PAPER #5.10

A PARAMETRIC STUDY OF DAYLIGHTING IN HIGH-RISE RESIDENTIAL BUILDINGS IN DHAKA, BANGLADESH

Sumaiya Mehjabeen[a], Ute Poerschke[a], Lisa Domenica Iulo[a]
[a]The Pennsylvania State University, State College, PA, USA

ABSTRACT

Daylighting has gained significant attention in the contemporary building industry to support a sustainable living environment. This is a challenge in the ever-increasing density of urban contexts. Empirical research shows that daylighting needs to be incorporated in regularly occupied spaces, including residential buildings. Surprisingly, residential buildings are designed largely ignoring daylighting necessity in compact urban contexts in developing countries. It is imperative to ensure enough daylighting ingress in residential buildings for improved health outcomes and comfort conditions. Daylighting in high-rise residential buildings in a dense urban context is still a less explored field in empirical research. This research presents an analysis of daylighting ingress relating to urban street canyon configurations of high-rise residential buildings in the dense urban context of Dhaka, Bangladesh. A parametric study is used to investigate the impact of building and street canyon geometry on daylight autonomy in high-rise residential buildings. Six residential building typologies are analyzed concerning how varied geometry of these typologies and the width of urban street canyons impact daylight ingress. The key aspects to analyze daylight autonomy in this study are building geometry, surrounding obstructions, orientation, and urban street configurations. These are computationally analyzed and visualized utilizing software, such as Rhinoceros, Grasshopper, and environmental plug-ins such as Honeybee and Ladybug. Observations from the study are used to understand how the geometric aspects of street canyons impact daylight autonomy in high-rise residential buildings in the dense urban context of Dhaka.

KEYWORDS

Daylighting; density; urban; high-rise; residential.

INTRODUCTION

Daylighting is as old as architecture itself and has a significant influence on building design. Before artificial lighting replaced natural light, the provision of daylight in every space was a necessity. Throughout history, daylight has influenced the building forms in numerous ways. The interaction between building design and daylighting depends on the importance of the availability of daylight in the building. The required illuminance quantity and quality are defined by the typology of a building. Building form determines the possibilities of daylight utilization and illuminance distribution patterns (Nancy et al. 2000). The factors related to building forms that influence daylighting design are - the ratio between exterior façade area and total floor area, building height, floor depth, floor-to-floor height, interior walls, and other obstructions (Compagnon 2004; Mayhoub and Carter 2010). Moreover, designing for daylight in a dense urban context asks for external urban factors, such as external obstructions, height and width of urban canyons, and other geometric aspects of the buildings (Cheng et al. 2006; Compagnon 2004).

Problem Statement

Urban densification and the construction of high-rise buildings are very specific problems related to daylighting in urban environments. In dense urban areas, the tall buildings that are built in direct proximity to each other, cover part of the sky, shade the windows from daylight and therefore, reduce daylight ingress and duration of sunlight. Moreover, tall buildings form street canyons, and these canyons reduce daylighting ingress inside the buildings. The use of artificial lighting is the only substitute in these cases. The negative psychophysical impacts of artificial lighting are well researched and proven (Boubekri 2008). Moreover, dependence on artificial lighting accounts for a substantial amount of energy use.

The development of high-rise buildings is a consequence of urban densification, expanding urban population, and economic growth. This is an ongoing issue, particularly countries in Southeast Asia. In many Southeast Asian cities, such as Dhaka, Mumbai, Hong Kong, Kuala Lumpur, high-rise residential buildings are abundant (Farea et al. 2012). According to Ahsan et al. (2016), the number of high-rise buildings has increased by three times between 2010 and 2016, whereas in Bangkok and Kuala Lumpur, the number has doubled over the same time (Ahsan 2016). Thirty percent of these high-rise buildings in Dhaka is of the residential type, and this number is increasing (Ahsan et al. 2014). The current number of high-rise housing may be much higher.

The Context of Dhaka

Dhaka, the capital of Bangladesh, is a fast-growing metropolis in south Asia and the 9th most densely populated cities in the world (United Nations Department of Economic and Social Affairs 2016). An influx of internal migration and spontaneous growth of population turned Dhaka into a densely built populous city with a demographic of 8.5 million people as of 2016 ("Atlas of Urban Expansion - Dhaka" n.d.). The built-up area density was 552 persons per hectare in 2014, and it is increasing every year ("Atlas of Urban Expansion - Dhaka," n.d.). The city suffers from extensive uncontrolled densification horizontally, and very recently, vertically in both planned and unplanned developments, resulting in a very compact urban form. The growing trend of constructing taller buildings is creating the problem of very dark and narrow urban street canyons (height: width aspect ratio 8:1 – 10:1). The two-way urban sprawl with no consideration of livable environmental factors, such as daylighting, etc. and proper infrastructure, including housing, has made Dhaka one of the unlivable cities of the world ("Global Liveability Ranking," n.d.).

It is a matter of concern that a majority of the existing residential buildings in Dhaka are built neglecting the adverse effect on occupant's psychophysical well-being, comfort, and overall urban environment (Ahsan, 2016). The high-rise buildings take advantage of the setback rules that require the buildings to have a minimum distance from the site-lines. These buildings obstruct admission of daylight forcing the occupants to rely on artificial means of lighting (Ahsan et al. 2014). This creates the problem of very dark interior living spaces in these buildings and the increased use of artificial lighting (Ahsan et al. 2014). This poses the following research question: How do building and related street canyon geometry affect daylighting in high-rise buildings in a dense urban context such as Dhaka, Bangladesh?

Review of Scientific Research and Recommendations on Daylighting

Parametric methods have been utilized in many pieces of research that intend to solve the complex problem of daylighting design utilizing available data and taking advantage of the flexibility of user manipulation (Eltaweel

and Su 2017). Daylighting design is dependent on many divergent criteria such as the latitude, longitude, sun-path, sun angles, dynamic sky conditions, solar irradiations, which makes the task complex and challenging. The parametric method can provide the utility of processing and connecting all the relevant data using specific software, which makes the process of analysis and decision making easier.

Over the past couple of decades, several studies have been undertaken to evaluate daylight ingress using parametric methods. Compagnon (2004) proposed a method to evaluate daylighting in urban areas by looking at irradiance values on building roofs and facades. This method has limitations as it does not consider the fact that daylight ingress is dependent on the depth of the building. In another research by Strømann-Andersen and Sattrup (2011), building depth and related urban canyons were analyzed. Their correlational study investigated building scale, urban density, and passive energy factors and established a relation between urban geometry and building operational energy, assuming a homogeneous urban setting. In PLEA 2006, Cheng et al. (2006) introduced another approach to investigate daylight availability by looking into daylight factors and urban density. This study presented the potential of daylighting simulations for urban design. However, the daylight factor approach is not a climate-based daylighting metric.

In recent years, climate-based daylighting metrics based on annual hourly indoor illuminance data are repeatedly investigated, promoted, and validated by researchers (Mardaljevic, Heschong, and Lee 2009) (Reinhart, Mardaljevic, and Rogers 2006). The Illuminating Engineering Society (IES) introduced Lighting Measurement protocol LM-83 that provides recommendations for using spatial daylight autonomy metric (sDA) to evaluate daylight availability in buildings. According to the IES recommendation, if a point in the work plane of an interior space receives daylight above 300lux at least 50% of the occupied time ($sDA_{300,50\%}$), it is considered 'daylit' ("Illuminating Engineering Society – The Lighting Authority" n.d.). According to LEED V4, the recommended $sDA_{300,50\%}$ level for an interior living space is at least 55% of a regularly occupied floor area ("LEED Green Building Certification | USGBC" n.d.). This is also adopted by the WELL building standard ("Light | WELL Standard," n.d.).

Research overview

This research intends to investigate the existing daylighting situation in a dense urban residential context of Dhaka, Bangladesh. The study is done first, at the building level, and then extended to the urban level. Six types of building geometry are tested at a building level to see the effect of building geometry. Then, the author investigated five rectangular building types at an urban level study. The urban level study focused on urban canyon configurations such as the width of streets, street adjacency to the longer side of building façade, and orientation. The research employs specific parameters to simulate hypothetical urban scenarios. This investigation helps to understand and identify the effects of building geometries and urban street canyons on daylighting in a dense city. Consequently, building orientations are also studied to understand how the buildings and urban canyons relate to each other. From this investigation, it is to be determined what geometric aspects of buildings and urban street canyons affect daylighting ingress in heavily obstructed high-rise residential buildings and whether a parametric exploration can help designers understand how daylighting ingress in densely built cities can be improved.

1. METHODOLOGY

1.1. The Climate and the Sun

The tropical city of Dhaka has a mainly direct sunlight climate. Conventionally, the principal daylighting strategy is window design with considerations for visual and thermal comfort. In dense areas with high-rise development, overshadowing cuts down a significant amount of incident daylight, and window design becomes a secondary concern. In such cases, urban street canyons and the shape of the buildings can be strategic areas for daylighting design. This research explored these specific strategies concerning daylighting in Dhaka. For this exploration, it is crucial to understand the sun's positions and angles throughout the year concerning the location of Dhaka.

The latitude of Dhaka is 23.8° North, and the longitude is 90.4° East. The Sun path diagram and solar chart presented in Figure 1 graphically show the year-round solar positions. These diagrams indicate that the sun altitude angles are high. The altitude angles for Summer and Winter solstices are 89.64° and 42.76°, respectively (calculated by the SunAngle program - https://susdesign.com/sunangle/). The sun path and solar chart diagrams are intended to show how the sun's position throughout the year affects the facades facing the west, southwest, south, southeast, and east, while the north facades have diffused daylight. The solar position is a critical factor for the daylighting design in Dhaka because of the high solar angles.

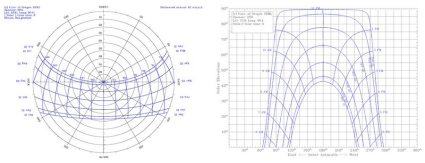

Figure 1. Sun path diagram and solar chart for Dhaka. (Source: http://solardat.uoregon.edu/unChartProgram.php).

1.2. The workflow

This research adopts a computational approach to analyze daylight availability in Dhaka. A parametric workflow is created based on existing scientific research. To calculate the sDA at a building level, the Radiance-DAYSIM approach is used and validated in many research (Saratsis, Dogan, and Reinhart 2017; Reinhart and Wienold 2011). Ladybug and honeybee plug-ins for rhinoceros-grasshopper use the Radiance engine to simulate daylight availability. The parametric workflow shown in Figure 2 is used to model, simulate, and evaluate building geometry and related urban street canyons. The workflow is divided into four sequential phases: (1) modeling the geometries and environment, (2) define and iterate the geometries which include defining the analysis geometry, creation of windows, walls, floors and ceiling, (3) annual daylight simulation, and (4) evaluation based on dynamic daylight availability metrics.

Typical meteorological year (TMY) weather data for Dhaka, Bangladesh, is used for the dynamic sky and daylight conditions.

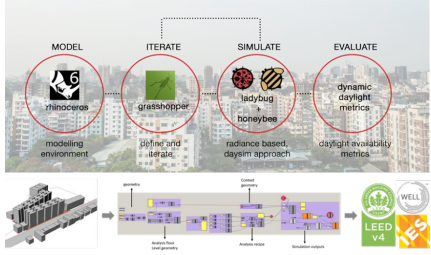

Figure 2. The computational workflow. (Author 2019)

1.3. Urban Geometry

The characteristics and form of urban residential buildings are a result of ever-evolving codes and regulations as well as climatic, socio-cultural, political, and technological factors. Dhaka's urban housing scenario is not any different from that. In this research, urban geometry is analyzed at the building level and the urban level. Several residential building form typologies are seen in Dhaka. Some typologies are adapted from the old courtyard houses with living spaces in the perimeters of the buildings with a central courtyard. Other typologies are variations and combinations of the central courtyard and vertical shafts at the outer shell of the buildings. The author identified six common residential buildings form typologies based on their geometry, which is shown in Figure 3. These are simplified massing diagrams for the typologies of residential building forms. The primary geometric types are square and rectangular forms of the building mass. Diagrams show the shapes of the buildings with external cuts and internal lightwells modified from existing residential buildings in Dhaka. Exterior protrusions and details such as windows, shading devices, are not shown. The number of dwelling units ranges from 4-8 per floor. At the urban level, the rectangular typologies were studied with varied urban canyon configurations. One example is shown in Figure 4.

1.4. The Parametric Research

The computational analysis is done in two levels –

1. Building level simulations:

A series of simulations were run for fourteen floor levels for each building typology. The total floor area is 8800 square feet in all six cases. For this set of simulations, the author set the building geometry as isolated objects on a ground plane with no obstructions. The freestanding geometry sDA values serve as references for the urban level analysis.

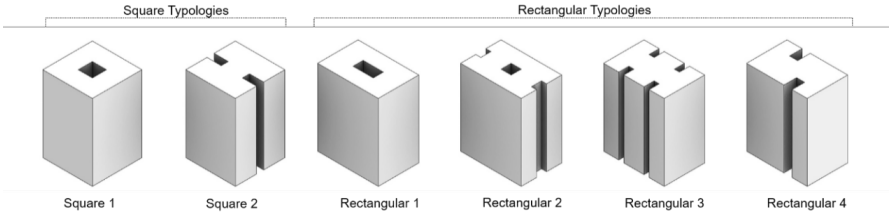

Figure 3. Six residential building form typologies. (Author 2019).

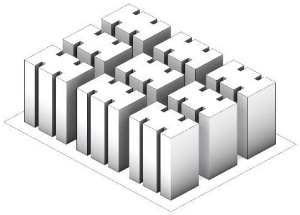

Figure 4. Example of a 3X3 grid geometry (R3 type) at the urban level. (Author 2019).

	Parameters	Details
Building Level		
	Building geometry	Shape, form
	External cuts and internal lightwells	Shape, area
Urban Level		
	Urban street canyons	Width of the adjacent street
	Canyon orientation	N-S vs E-W
	Context	Relative compactness or dispersion
	Obstruction of solar penetration	Overshadowing from adjacent buildings

Table 1. Building and Urban Level Parameters. Source: (Author 2019)

2. Urban level simulations:

For the urban level simulations, only rectangular typologies were studied. Another geometric type with no external or internal lightwell is included in the study (R0) to see how it performs in comparison to the other four rectangular types. Each of five the rectangular typology is simulated and analyzed in hypothetical 3 X 3 grids of repeating geometry with streets. The urban level study for five rectangular typologies are done in the following scenarios –

i. North-south building orientation, 20' streets
ii. East-West building orientation, 20' streets
iii. North-south building orientation, 30' streets
iv. East-West building orientation, 30' streets
v. Wider East-West streets
vi. Wider North-south streets

The proposed simulation approach features parameters in the parametric modeling environment to allow for an understanding of daylight availability and increasing simulation complexity. These variables affect the annual simulation analysis either by adding to the accuracy level or by impacting the daylight availability. Table 1 summarizes the parameters explored in this study. The Radiance parameters are set at the following levels- the ambient bounces (ab) at 5, ambient divisions (ad) at 1000, ambient resolution (ar) at 300.

The computational methodology used here, while effectively producing relevant results, makes some important simplifying assumptions for simulation to minimize calculating irrelevant objects and shorten the simulation time. A key assumption is that there are no interior walls, partitions, structures, furniture, or other internal obstructions in the building. Another key assumption is, the massing of the building is simplified, not considering the façade treatments such as exterior protrusions, verandas, other overhangs, or shading devices concerning the windows. It should be noted that the sDA computed in this exploration is not the actual sDA required by LEED that complies with IES LM-83 since there are no shading devices, such as blinds, applied in the parametric model. The sDA metric is not originally intended for residential development and there are very limited guidelines for evaluating the daylighting performance of residential buildings. The exterior wall thickness and the building elevator and stairwell core were not deliberately defined in the geometry. The sDA calculated in this research is the output of the Honeybee annual daylight simulation and is referred to as sDA henceforth. ASE metric was not tested because shading devices are

not incorporated, and this research focuses on daylighting ingress concerning building and canyon geometry. Further research is needed to analyze visual and thermal comfort. Within the limitations imposed by these caveats, this computational framework can be used to effectively calculate research sDA values and generate data necessary for this research.

2. OUTCOMES

2.1. Building level simulations

Figure 5 shows annual daylight autonomy false-color graphics on the tenth-floor level for all six building typologies for comparison. The effect of changing floor levels on $sDA_{[300lux][50\%]}$ percentages is shown in Figure 6, where the graph presents the sDA values on all the floors except the ground parking level. These data visualizations demonstrate that the sDA percentages for a specific floor level in all building typologies vary within a small range and the variation is highest in the 14th-

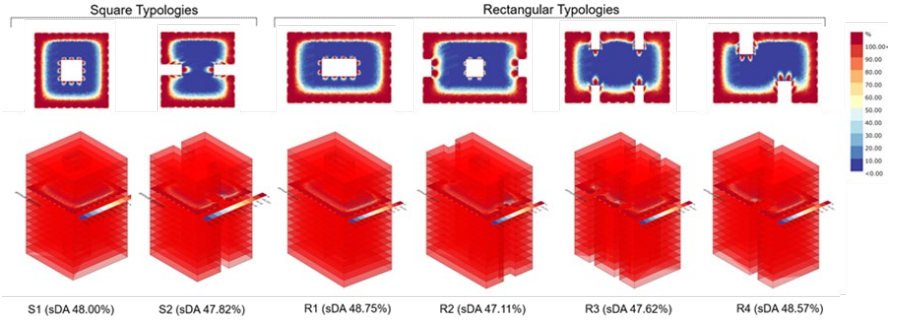

Figure 5. Building level study for daylight availability- example level 10th floor (Author 2020).

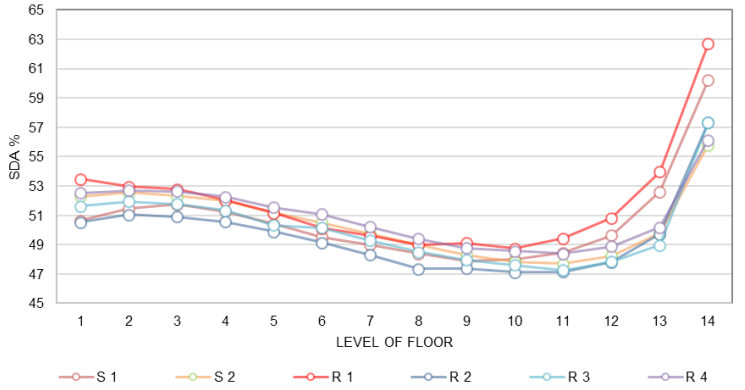

Figure 6. Floor-by-floor sDA plot for the six typologies (Author 2020).

floor level. The R4 type presents the minimum difference in floor-to-floor sDA percentages, whereas the R1 shows the highest variation. Although type R4 has the longest perimeter and thus more glazed surfaces, the upper floors get comparatively lower percentages of sDA than R1. It can be speculated that R1 type has uninterrupted facades that benefit from the unobstructed direct sunlight. Figure 5 also shows that these exterior cuts decrease the direct sunlight ingress. The other types have wider shaded regions between red and blue extremes, mostly near the windows, whereas the R1 type has uninterrupted red color adjacent to the perimeter and the less shaded area between the two extremes. A similar effect can also be seen in S1 and S2 types. These external cuts may be beneficial to reduce glare and overexposure to direct sunlight. The impacts of having these external cuts were also explored in the urban level investigation discussed later. The sDA percentages in all cases are somewhat at a good level principally because of unobstructed direct sunlight exposure. It is intriguing that in an isolated geometry, the lower floor levels receive more daylight compared to the middle levels. One assumption can be made here that this is due to the diffused sunlight reflected from the ground surface penetrating the building interiors through the glazed openings. The upper floors receive more daylight than the lower floor because of sunlight exposure, whereas the lower floor levels do not receive direct sunlight when the sun is at a higher position in the sky.

In the isolated geometry study, the diffused daylight from the ground, the sun positions, and the external cuts in the façades play crucial roles in daylight ingress. Interestingly, the data also shows that the shape of these typologies does not have any significant effect on spatial daylight autonomy for isolated buildings, and all the typologies seem to have an almost similar level of daylight ingress year-round (Figure 6).

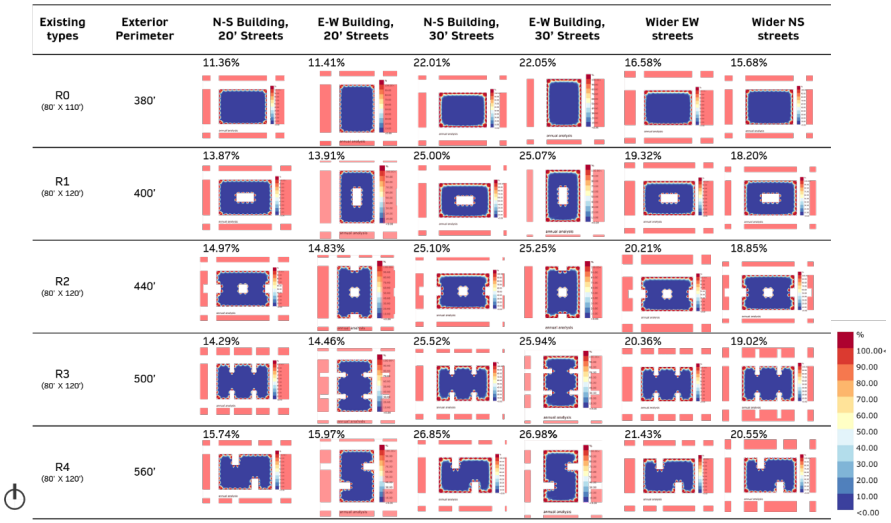

Figure 7. Urban level Study for Daylight Availability: Investigated floor- level 10. (Author 2020)

2.2. Urban level simulations

Figure 7 shows the data visualizations from the thirty annual daylight simulations for the 10th floor of the five rectangular types in the six hypothetical urban scenarios. Predictably, the matrix depicts that having a longer building perimeter, and thus, having more glazed surfaces allow more daylight ingress. Therefore, type R4 performs slightly better than the other types. In contrast to the building level study, type R1 did not perform better than the other types in the urban level study. The external cuts may be more useful in urban scenarios than isolated geometry because the diffused light reflected or scattered from surfaces of nearby buildings influence daylight ingress. There are slight improvements in the sDA with an increase in the perimeter length and glazed surfaces. On the other hand, increasing street widths around the building from 20 ft (6 m) to 30 ft (9 m) resulted in significantly higher spatial daylight autonomy percentages. This outcome reinforces the hypothesis that the geometric configuration of urban street canyons, in this case, the width of the street canyon, plays a vital role in daylight autonomy. In comparison, building shapes seem to have less effect on daylight autonomy. Moreover, having different street widths shows slight variations in the sDA which shows that having the longer side of the building along the wider street performs better in terms of daylight ingress.

CONCLUSION

The daylighting analysis in this research indicates that, in the extreme urban scenarios of Dhaka, the width of urban street canyons has a significant effect on daylight autonomy. For example, a ten feet width increase from a twenty feet street increases the sDA calculations at least 60% from the respective cases with twenty feet streets. In comparison, building shape and form has some, albeit minimal, impact on daylight ingress. For example, up to a 13.5% sDA increase is observed for buildings with external cuts (R4) compared to buildings with internal lightwell (R1). A conclusion can be drawn considering these findings, that it is critical to address the width of the urban canyon while designing for such density. Additionally, the urban street widths adjacent to the longer façades of the high-rise developments are critical for daylighting in the living spaces of residential apartments built in density, along with other factors traditionally addressed in daylighting design. Therefore, the regularly occupied spaces in residential buildings of Dhaka, such as the bedrooms, study areas, and family living areas, should be located along the longer side of the building façade to benefit from daylight. The building level parametric study shows that the internal lightwells in high-rise residential buildings performed poorly regarding daylight ingress, allowing daylight ingress only on the top 4-5 floors in a 15 storey building, whereas the external cuts are effective for all floors. Further research can be done on the different floor levels to see the difference at the urban level. Additionally, investigations can be done to investigate realistic geometric configurations of urban canyons with more simulation complexity to further explore daylighting in dense urban areas.

PAPER #5.11

APPLICATION OF ARTIFICIAL NEURAL NETWORK IN SOLAR RADIATION PREDICTION FOR REAL-TIME SIMULATION

Hany Gaballa[a], Yeo Beom Yoon[a], Byeongmo Seo[a], and Soolyeon Cho[a]
[a]College of Design, NC State University, Raleigh, NC, USA

ABSTRACT

Solar radiation is one of the essential energy sources in our life. The availability of solar radiation as a parameter is important in getting the most effective use of solar energy resources in design or energy simulations. Acquiring real-time solar radiation data is costly; most of the available data are historical. Predicting solar radiation is considered an essential process for developing real-time weather data required to run real-time building simulation to track the building systems' performances. Artificial Neural Networks (ANNs) have a good application history, especially in predicting solar radiation, which increased in the past years due to its ability to solve complex and nonlinear tasks. This paper aims to use an ANN model to predict hourly global solar radiation using only temperature and humidity, which can easily be accessible in the Building Automation System (BAS). An ANN algorithm had been developed in a previous study (Gaballa & Cho 2019), which shows that using predicted global solar radiation to run building energy simulation during the summer season gives a good accuracy based on the ASHRAE Guideline 14. In this paper, the ANN model mentioned earlier is tested throughout the entire year. The ANN model has some variables, i.e., the number of hidden neurons, the number of epochs, and the learning rates. For each season, the variables are calculated to give the most accurate results with minimum error difference. TRNSYS software is used to calculate direct and diffuse solar radiation from the predicted global solar radiation. After the prediction method, a new weather data file is developed according to the predicted data using the EnergyPlus weather converter tool. The EnergyPlus program is used to simulate a case study office building. Using two weather files (measured and predicted), a comparison between the measured and predicted cases is discussed.

KEYWORDS

Artificial Neural Network; solar radiation prediction; real-time building energy performance.

INTRODUCTION

Every day, technologies become more advanced to solve daily and significant problems. Artificial Intelligence (AI) is one of the advanced technologies used in various fields. This paper discusses how AI technologies can help in diagnosing the building`s systems efficiency.

Simulation software makes the process of making the right decision easier; it helps in making that in the early design stage to save time and money. After the construction process, it is still hard to diagnose the building`s systems using simulation software since it uses historical data. That is why developing real-time weather data is necessary.

Solar radiation data is considered one of the most effective parameters in simulation (Qazi et al., 2015); also, it is the most important renewable energy source on earth (Gana and Akpootu, 2013). According to Wang et al. 2011,

there is a shortage of solar radiation data preventing a great use of solar energy. For this reason, solar radiation data is essential. While the measuring process is costly, predicting solar radiation became necessary for real-time building performance. Not only for that purpose, it also helps in many other different industries such as, sizing PV planets (Egido, and Lorenzo, 1992) and increasing agricultural productivity (Dohleman & Long, 2009). According to Gungor and Yildirim, 2012, global solar radiation data is the required information as an input parameter for developing solar energy systems.

In this study, an ANN model is used for global solar radiation prediction, which had been revealed from different studies that ANNs are superior in prediction problems (Mubiru and Banda, 2008). Only easily accessible data from Building Automation System (BAS) is used as input parameters in the ANN algorithm, which is temperature and relative humidity to predict hourly global solar radiation. The main goal of this paper is to measure the accuracy of running real-time building simulation using the predicted weather files, which is developed using the predicted solar radiation from the ANN model. The simulation process using EnergyPlus is performed to run two different scenarios using two different weather files, the measured 2018 and the predicted 2018 weather files. A comparison using cooling and heating loads are analyzed for the entire year to see the efficiency of the ANN algorithm.

1. PREVIOUS STUDIES AND GOALS

ANN models are found to have applications in different fields of science and technology. ANN algorithms extract the information and learn from data, so it can be used to solve nonlinear problems. A study conducted by Amit et al. 2014, concluded that ANN techniques have more accuracy in comparison to the conventional methods in predicting solar radiation. The ANN prediction accuracy is found to be dependent on a combination of input parameters, training algorithm, and architectural configuration.

Previous studies used a combination of different parameters which influence the solar radiation prediction such as longitude, latitude, altitude, time, solar zenith angle, air temperature, wind speed, relative humidity, cloud cover, rainfall, etc. Historical data of these parameters in a specific location is used as input to the ANN to predict solar radiation at this location. However, this paper aims to focus on easily measured data from the BAS, which are temperature and relative humidity to be used as ANN input parameters.

It was found through the prediction process in the ANN model that there is no rule for selecting a specific number of hidden neurons or learning rate; otherwise, a try and error is performed. Such as a previous study done by Chiteka and Enweremadu in 2016, the author suggested some numbers (3, 7, 10, 13, and 20) for hidden neurons to be tested. While in this paper, an optimization process is performed to test all possible combinations of three variables; the number of epochs, the number of hidden neurons, and the learning rate.

Previous studies interested in real-time building performance used onsite measurement tools required to develop weather files. Some other studies used the Seo model (Seo, 2010) to calculate solar radiation data that requires more than six parameters, which is not readily available. This paper aims to use the ANN prediction model to develop a new weather file to be used in simulating the real-time building performance.

2. RESEARCH METHOD AND ASSUMPTIONS

2.1. Data acquisition

One of the most effective steps in the ANN algorithm is how to deal with the data set required to run the algorithm. In this paper,

2018 weather data files for Raleigh-Durham, NC, weather station represent real measured data. Temperature, humidity, and solar zenith angle picked from the 2018 weather files are used as a testing data in the ANN model to predict the global solar radiation. Data were divided into four seasons. Hourly global solar radiation in each season was predicted separately. In this way, it makes the prediction process more accurate as the set of data becomes more precise to each other. The training data is differentiated for each season. For spring, summer, and fall, the training data set are picked from Typical Meteorological Year (TMY) for Raleigh-Durham weather files. While for winter, it is selected from the 2017 Raleigh-Durham weather files as it gives more accurate results than using TMY weather files. By running a separate ANN algorithm for the four seasons, a predicted global solar radiation is possible after an optimization process. This process includes the calculations of the most accurate variables that affect the ANN model. The variables are the number of neurons, number of epochs, and learning rate. After the optimization process, the hourly global solar radiation for the whole year is available. TRNSYS software is used to calculate the direct and diffuse solar radiation from the predicted global solar radiation through the Perez model. Then, the EnergyPlus converter program is used to develop a new EnergyPlus weather (EPW) file to be called (Predicted_2018) weather files using the predicted global radiation from ANN and calculated direct and diffuse from the Perez model.

2.2. ANN algorithm optimization process

Generally, there are three basic methods in Machine Learning (ML), such as supervised learning, semi-supervised learning, and unsupervised learning (Muller and Guido, 2017). The summary of a detailed definition and abilities for the three methods was published by Seo B. et al. (2019). Artificial Neural Network (ANN) is considered one of the supervised learning that belongs to ML (Mitchell, 1997). ANN uses the processing of the human brain as a basis to mimic its behavior, trying to learn from previous tasks to solve complex patterns and prediction problems. To learn from experience, ANN uses two algorithms; feedforward and backpropagation (Puri M, 2016).

ANN consists of three layers; input layer, hidden layer(s), and output layer in order. A random weight factor is assigned to each layer of the input layers. Each layer has connections to the next layer, but there are no back connections; this process is called feedforward. The backpropagation turns over this process to train the algorithm by calculating the error and adjusting the randomly assigned weights backward. The whole process that is repeated is called an epoch, which aims to reduce the error value. There is an essential parameter in the backpropagation process called learning rate, which settles the weights` changes at the end of each epoch (Rezrazi et al., 2016). An activate function is used to simulate the behavior of the neurons, which differentiates depending on the application of the algorithm. In this paper, the activation function used is the sigmoid function, which gives values between 0 and 1; this kind of feature is commonly used for non-linear problems (Kyurkchiev and Markov, 2015).

The performance of the ANN model is mainly dependent on the input parameters, as Rezrazi et al. (2016) mentioned that the selection of the most appropriate input variables is essential to improve the algorithm efficiency. This paper aims to predict the hourly global solar radiation using easily accessible data from the Building Automation System (BAS), such as temperature and relative humidity. An ANN model was developed depending on these data set and mentioned in more detail in the previous study (Gaballa and Cho, 2019). This ANN model uses temperature, humidity, solar zenith angle, and time as input parameters to get the desired output, which

is the hourly global solar radiation (Figure 1). This model is used four times for the four seasons separately using different input data sets.

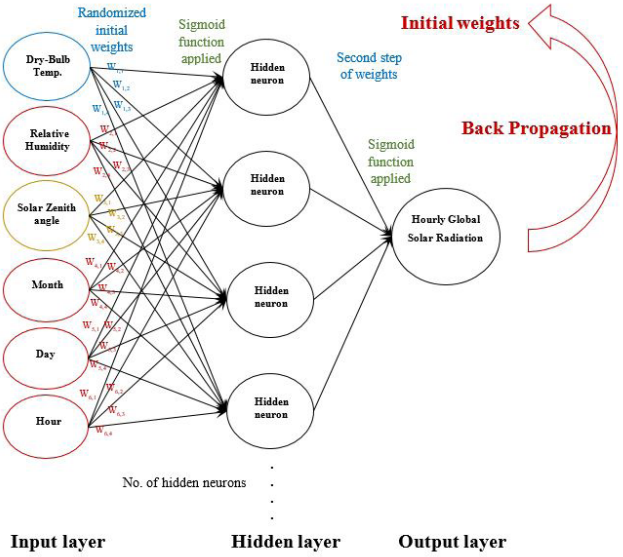

Figure 1. ANN architecture

An optimization process is performed, which includes a calculation of three different variables; the number of hidden neurons, the number of epochs, and the learning rate. The optimum variables for each season were calculated to be used in the ANN model to predict the most accurate global solar radiation. Through the optimization process, a range and a distance for each variable were given. The range for the number of hidden neurons, learning rate, and the number of epochs is as follows; 10:100, 0.01:1.0, and 100:1000, respectively, while the distance was 10, 0.01, and 100, respectively. Table 1 shows the optimum variables` value for each season.

Season	Number of hidden neurons	Learning rate	Number of epochs
Spring (March 1-May 31)	60	0.82	200
Summer (June 1- Aug 31)	80	0.03	600
Fall (Sept 1-Nov 30)	10	0.07	600
Winter (Dec 1- Feb 28)	20	0.02	100

Figures 2- 5 show comparisons between the predicted and measured global solar radiations for each season individually. The horizontal axis shows the date and time every hour, while the vertical axis shows the global solar radiation in Wh/m2.

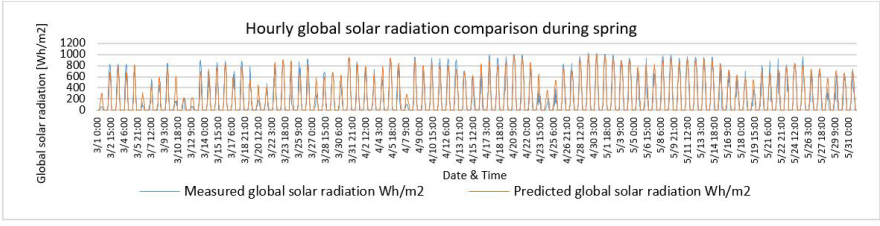

Figure 2. ANN results from comparison during spring

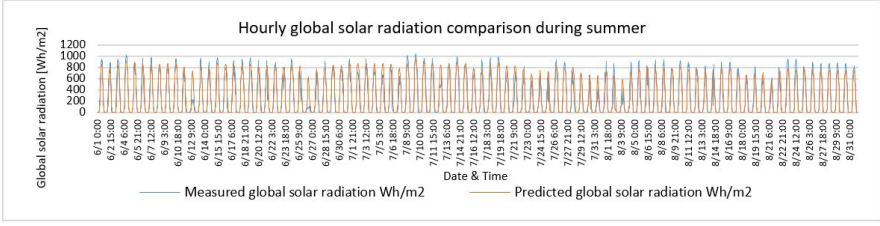

Figure 3. ANN results from comparison during summer

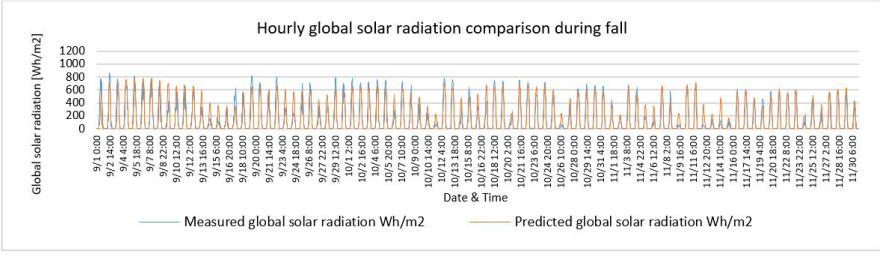

Figure 4. ANN results from comparison during fall

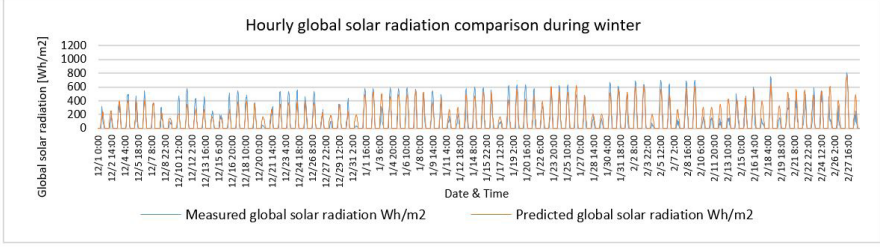

Figure 5. ANN results from comparison during winter

2.3. Simulation

EnergyPlus (US DOE, 2010; Crawley et al., 2001) is one of the most popular software programs used for the whole building energy simulation and analyses (Basarkar M. et al., 2011). In this paper, EnergyPlus V8.9.0 is used in simulating two different scenarios through two different weather files; the predicted 2018 weather files through the ANN model and the already measured 2018 weather files.
A commercial building located in Durham, NC, was chosen as a case study building. The building consists of three floors with a total area of 4,024 m2. There are 29 different zones divided into the three stories; in the EnergyPlus software, each space was assigned to the related zone. The building has 1,690 m2 glazing area with a window to wall ratio of 42%, as shown in Figure 6.

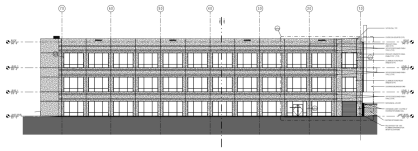

Figure 6. EPA building west Elevation

EnergyPlus model inputs need full information of the building; geometry, materials, openings, location, HVAC system, etc. The two scenarios are considered the same for the building`s configurations except for the weather files used to run the simulations. The simulations were performed for the whole year to make a comparison.

3. RESULTS AND DISCUSSION

As mentioned before, this study aims to measure the effectiveness of using the ANN model in prediction by comparing the two cases, using the measured and the predicted weather files. Heating and cooling loads are selected as indicators to make this comparison. The CV(RMSE) and NMBE are calculated to measure the uncertainties between the two cases. Table 2 shows these percentages between the two cases for the entire year, and as shown, cooling and heating loads differences meet the requirements of ASHRAE Guideline 14 as less than 30% for CV(RMSE) and less than 10% for NMBE (ASHRAE, 2014). Figure 7 shows the total loads comparison for the entire year and the difference between predicted and measured loads.

Loads	CV(RMSE)	NMBE
Heating loads	23.3%	10.5%
Cooling loads	13.7%	-5.9%

Table 2. Statistical measures between measured and predicted loads for the entire year

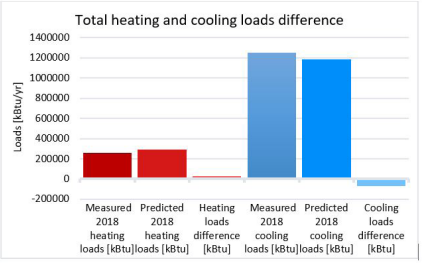

Figure 7. Total heating and cooling loads comparison

Loads are calculated for each season separately to make a clear comparison. Table 3 shows the CV(RMSE) and NMBE for each season. The results show that in summer and winter season, cooling and heating loads are more efficiently predictable while in the swing seasons, the accuracy decreased but still within limits. For more clarity, Figures 8-13 show comparisons between the measured

and predicted loads for each season with zero load values ignored.

Loads		CV(RMSE)	NMBE
Spring	Heating loads	33%	11.8%
	Cooling loads	18.7%	-8.6%
Summer	Cooling loads	9.4%	-3.9%
Fall	Heating loads	26.9%	10.7%
	Cooling loads	16.2%	-7.5%
Winter	Heating loads	18.9%	10.1%

Table 3. Error difference between measured and predicted loads for each season

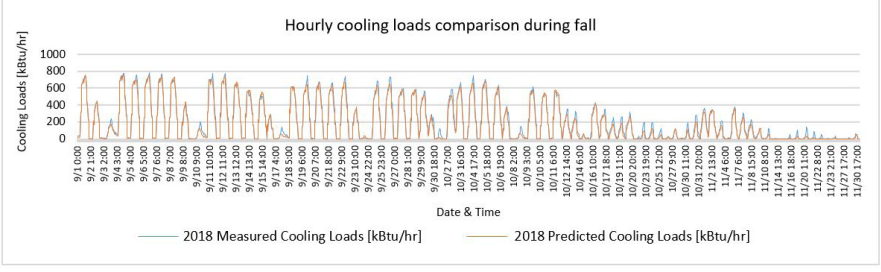

Figure 12. Cooling loads comparison during fall

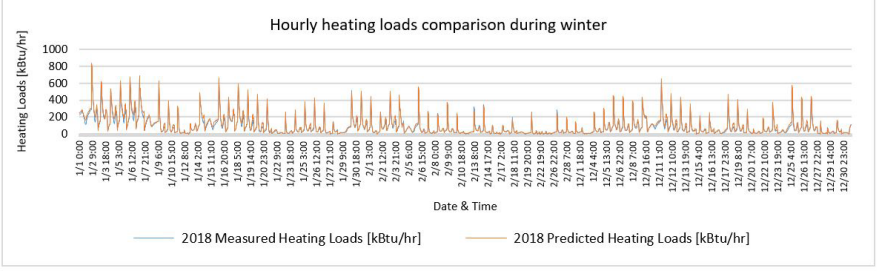

Figure 13. Heating loads comparison during winter

CONCLUSIONS AND FUTURE WORK

This paper presented an ANN algorithm for solar radiation prediction, which makes developing real-time weather files possible. Only temperature, relative humidity, and solar zenith angle are used as input parameters, which means that the ANN model uses only readily accessible measured data from the BAS to predict global solar radiation. Real-time building energy simulation is demonstrated using the developed weather file (Predicted_2018). The simulation is performed using EnergyPlus software for the whole year. A comparison between the measured and predicted building performance is provided using two weather files, measured 2018, and predicted 2018 weather files.

The results show that the cooling load's difference is 13.7% (CV(RMSE)) and -5.9% (NMBE), while the heating loads difference is 23.3% (CV(RMSE)) and 10.5% (NMBE). Looking deeply into each season, for summer, the CV(RMSE) for cooling loads difference reaches only 9.5%. Besides, in the winter season, the CV(RMSE) for the heating loads difference is only 18.9%. These results are found to meet the tolerance range addressed in ASHRAE Guideline 14.

In conclusion, this method gives a reasonable error difference, which makes it possible to predict real-time building performance. Building operators can compare these predictions with the actual measured data and identify any potential problems that happen in the building systems to take any actions required early.

Two different methods were used in calculating direct and diffuse solar radiation from the predicted global solar radiation, EnergyPlus converter software, and TRNSYS software. Although the two programs use the same Perez model, the results are significantly different. For instance, CV(RMSE) for cooling in summer, the EnrgyPlus converter shows 21.9%, but TRNSYS 9.5%.

For future studies, the pros and cons of different methods used in calculating the two derivatives of solar radiation from the global solar radiation should be presented.

PAPER #5.12

THE SPATIAL BLOCK: NATURAL VENTILATION AS AN ARCHITECTURAL INSTRUMENT

Ezgi Bay[a]
[a] Illinois Institute of Technology, Chicago, Illinois, USA

ABSTRACT

The housing deficit is a global problem. In Turkey, the governmental agency 'TOKI' has proposed solutions to inadequate and unaffordable housing. However, it has been widely criticized that its residential projects are based on 'standard regulations' and 'repetitive, high-rise typologies'. This approach is discussed by researchers because of its limited exploration of contemporary needs of people. Also, the limited and low quality architectural and urban conditions in these projects marginalize the living standards of the residents.

Sprawling rapidly throughout different climate regions in Turkey, one of the permanent complaints of TOKI residents is related to indoor thermal conditions. As consequence of this 'homogenization effect', overheated and underheated conditions are experienced. In these 'naturally ventilated buildings', few considerations are given to the surrounding environment and it is ignored how the residential units perform under extreme seasonal circumstances.

Through post-occupancy evaluations, this paper investigates a TOKI built in hot and dry climate. Also, it brings new 'typological' alternatives analyzed through energy simulations and computer fluid dynamics (CFD). Results illustrate the dynamic of thermal stress, and alternatives of using prevailing winds in consonance with building form to alleviate these problems.

Summer heat stress periods and cross ventilation limitations are studied through Indoor Temperature, PPD and ACH analyses performed IES-VE software. The link between thermal comfort and indoor microclimate in TOKI housing can be better with the reformulation of its residential typologies by proposing a 'Spatial Block' approach.

KEYWORDS

Post occupancy evaluation; hot and dry climates; natural ventilation; residents' satisfaction; CFD.

INTRODUCTION

Informal settlements appeared in cities due to the housing demand of high population in many countries during the industrialization period (Keles 2006, Majale 2008). This phenomenon is described as over-crowded, temporary, probably illegal and unhygienic by Uzun et al. (2010). In the case of Turkey- with the last decade migrations mostly from Syria- the population has reached to 82 million today (Fig.1). Parallel to the urban-rural balance shift, the structure of cities has changed. This generates a serious pressure on urban areas, where housing demand has emerged, and informal settlements appeared through the years.. The current housing deficit in Turkey has been solved through a governmental institution called the 'Mass Housing Administration' (Toplu Konut Idaresi Baskanligi / TOKI). Since 1983, TOKI has replicated a high-rise typology all over the country with the purpose of providing ownership to higher number of people. Gur and Dostoglu indicate that 70 % of TOKI users prefer these projects due to the low cost compared to other housing possibilities (Gur et al. 2011).

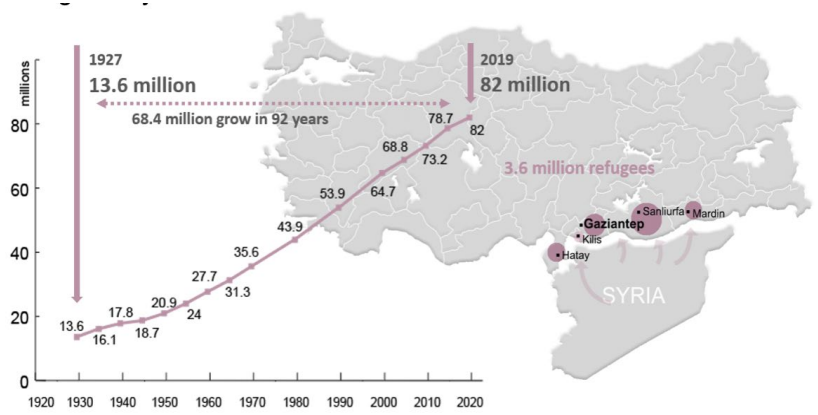

Figure 1. Population growth in Turkey. Source: (The graph was created data from Turkish Statistical Institute)

Applications of TOKI Administration to meet low-income people's necessities within financial margins result that the projects have serious limitations in terms of other aspects. Therefore, TOKI housing has become the object of multidisciplinary research. Although TOKI provides better infrastructure and hygienic environments for these groups, post occupancy evaluations (POE) by various researches show that design decisions on urban form, residential typology, and building enclosure create negative outcomes (Bay 2019; Savran 2014; Turan 2010; Karaca 2008). As Choguill (2007) mentioned, 'meeting the needs of the present without compromising the ability of future generations to meet their own needs', will not be successful in long term. For sustainable environments, housing problem should be discussed with multidimensional perspectives such as the involvement of the community in all phases (planning, constructing, maintaining), environmentally friendly material selection, quality, affordability and providing ideal density. Although there are many studies about TOKI housing in social and political sciences, there has not been much investigation about these projects in terms of their environmental sustainability. Applied research conducted on energy efficiency in these buildings is relatively limited. From the literature review, it is concluded that a key research area in TOKI project is their sustainability which is a research gap. For example, how natural forces such as sun or wind can be used to improve their indoor conditions. Therefore, this paper moves along the idea of using the environmental forces to satisfy comfort demands of communities.

The objectives of this paper are:

(1) To identify the current conditions of a TOKI housing project on a hot and dry climate.

(2) To study natural ventilation and aerodynamic flow effects to improve indoor conditions.

(3) To interpret residents' opinions about their units.

(4) To investigate residential typologies that can be more adequate for hot and dry climates in Turkey

1. STUDY CASE AND ITS PROBLEMS

In Turkey, one of the most common complaints expressed by the TOKI residents is their thermal dissatisfaction directly related to their specific weather conditions. This study is conducted on a TOKI residential project in the city of Gaziantep. Located in the South-Eastern Anatolian region, Gaziantep is a city with a hot and dry climate. In the studied project, residential units are overheated and cause higher level of dissatisfaction in the summer months. Buildings in Gaziantep have high cooling loads in warm seasons. As a climate zone 3B (ASHRAE 90.1) and Csa- Mediterranean Climate (Köppen), summer temperatures are above 30°C while winter are cold (Turkish State Meteorological Service). In this sense, a weather data analysis developed in IES VE shows that in at least 2600 hours per year (30% of the time), there is no high humidity that can cause thermal stress in the city. In this sense, low relative humidity, high evaporation and temperature differences between day and nighttime during summer months favor the potential of using the city's southwest prevailing winds for natural ventilation of buildings. (Fig. 2). Under these weather circumstances, natural ventilation techniques favor the connection between better living conditions and better thermal environment at lowered cost, particularly on the reductions to mechanical cooling (Olgyay, 2015). This paper explores building form as a manner to improve the relationship between human thermal comfort and indoor microclimate in TOKI housing. The case study 'TOKI Etiler project' is composed by six rectangular towers each one with 12 stories (Fig.3). These are the highest structures in the middle of a low-rise neighborhood. In the recent time, the city has had a growth rate of 56% receiving the highest number of Syrian refugees in the country. With nearly two million of inhabitants, the city's housing demand is expected to rise quickly in the coming years.

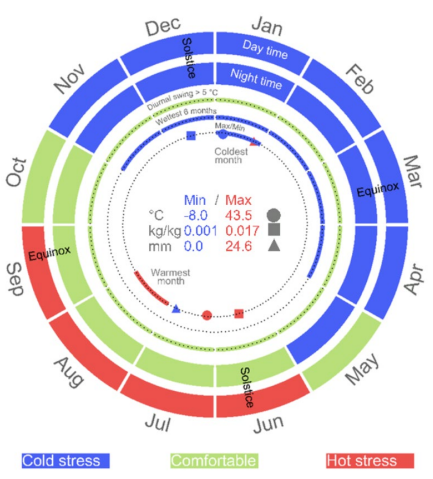

Figure 2. Weather analysis in Gaziantep locating in a region with high cooling demand. Source: (The graph was created in IES-VE by the author)

Figure 3. TOKI Etiler Project in Gaziantep. Source: Author, 2019

2. METHODOLOGY

This research employs a mixed methods approach to integrated qualitative and quantitative data collected during a field study carried out in the TOKI Etiler Project. Three methodological steps are used: (1) Computational Fluid Dynamics (CFD) simulations, (2) Post Occupancy Evaluation and (3) a Generative Design Process. First, energy modeling was used to observe the real conditions in the studied project. The second step surveyed the residents about their environment to obtain information regarding the performance of the residential typology. In the third step, an iterative design process was used for producing an alternative typology for this mass housing project to enhance passive cooling in this hot and dry climate region.

2.1. Computational Fluid Dynamic (CFD) simulations

In this study, three 'key performance indicators': indoor temperatures (T), air renovation in units (ACH), and percentage of people dissatisfied (PPD) were used for comparison between a baseline and a proposed case. In addition, typical flow regimes and their interaction with the high-rise typology is observed through computational fluid dynamics (CFD) through airflow diagrams. CFD simulations (external and internal) were tested in IES-Microflo. The time lapse of external simulations is a 5-month period (from May to September while the time lapse of internal simulations is applied single instances in time in specific days. Three dates which have the highest airflow rate were selected: May 17, June 14, and September 21) For external airflow analysis, wind direction, meteorological wind velocity and exposure type were used as inputs to obtain streamlines in a CFD grid. Through a graphical analysis of velocity profiles, the difference of airflow rate on windward and leeward facades was observed along the buildings. For the weather data, the typical meteorological year (TMY 15) file for Gaziantep was used.Ç For this step, three external analysis were conducted in Microflo that is based on Finite Volume Method. It uses steady state three-dimensional convection-condition heat transfer and flow model. First, aerodynamic flow effects were investigated in the baseline model. After a preliminary test series on generic courtyard buildings, a mid-rise with an equivalent urban density is proposed as an alternative typology. A graphical analysis of velocity profiles is done for different levels. The difference of airflow rate on windward and leeward facades was observed. Then, three consecutive test series examined the flow behavior in courtyards with gradually changing 'width to height ratio' and openings. After observing courtyards with the same orientation as the TOKI towers in Etiler project, the series were repeated with courtyards aligned to the prevailing winds. It showed that narrower courtyards (w/h of 3.75) have a larger funnel effect, proportional to a more constant flow acceleration of the prevailing streams. Same steps were performed in the development of the proposed case. In this process, the aim was to find possibilities that can enhance the interconnection of airflow across courtyards. So, eight courtyard models were analyzed through velocity profiles. Obtained results of speeds on inward and leeward facades showed that homogenous profiles were targeted between first and top levels.

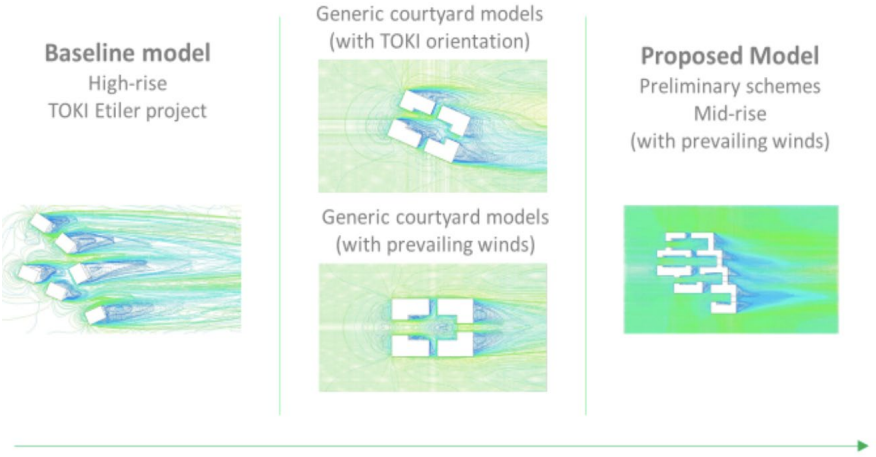

Figure 4. External analysis steps in IES-VE. Source: (Author 2020)

2.2. Post occupancy evaluation

The main goal of this step is to understand objective and subjective factors which influence the TOKI Etiler residents' satisfaction. A sample of 143 residents representing their household (50 % households of the project) responded to a questionnaire. This was a random sample that the probability of a subject being selected depended on those who were at home during the surveying time and were interested to be surveyed. Majority of respondents expressed that without open spaces and major climatic control, families try to adapt their lives into the high-rise. The complaints about life in towers specifically about units, surroundings lack functionality and thermal control, generate community disintegration particularly senior residents. In this project, a minority of families with more economic resources invests in space conditioning. However, these express that it is used only for overheated periods when other neighbors rely on open windows to deal with the harsh summer. Overall, windows are opened to enhance cross winds through the units, this is the most used alternative. Also, responses to questions on window indicate the windows in the unit that are frequently opened during the daytime. Balcony doors are the type that remains open for a larger period of time, since these have the larger opening area. Contrary to its common use for ventilation, some of these doors' balconies are modified by residents, limiting airflow from outdoors due to reduced opening area. Related to thermal sensation, residents manifest in a high proportion a 'warm' sensation in winter (with a central heating system). However, during the summer month more that 60 percent of people express a thermal sensation "above neutrality" already with a "light" clothing value. In addition, only 25 percent of residents express an acceptable satisfaction with their indoor thermal conditions. However, a dissatisfaction of 80 percent about their outdoor areas shows the lack of climate control of this project (Fig. 5). Moreover, in SPSS software, the interdependence between air flow

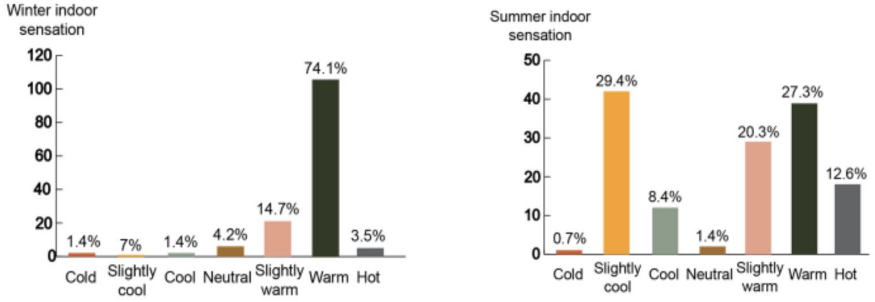

Figure 5. Thermal sensation of residents in winter and summer. Source: (Author 2020)

performance and thermal sensation is investigated. A positive correlation shows that when air flow increases in units, there is also an increment of 0.357 in the thermal satisfaction. From coefficient table, 'adjusted R square' shows that 12 percent of the variance of the thermal sensation is predictable from air performance.

2.3. Generative design process

Previous methodological steps made evident the potential of a residential typology (building mass) that can take advantage of its form to enhance passive cooling. In this sense, a scenario called "Spatial Block" was proposed. While energy and external CFD analysis of TOKI project provided information of how to assess the baseline model, generic models with courtyards shaped the concept of 'porosity'. The effect of voids for decreasing cooling loads in multi-story buildings was mentioned by Muhsin et al. (2017). This concept is tested through not only courtyards also terraces, porches and balconies as transitional spaces. Furthermore, the air flow potential the porous structure is explored through generative design techniques. For this step, the Grasshopper plug-in for Rhinoceros that allows processing the following algorithmic and geometrical operations was used (Fig. 6). First, by using five courtyards whose width to height ratios were determined through previous steps, a building mass was generated. This model was comprised of 5mx5m cells – 25 m² cell was

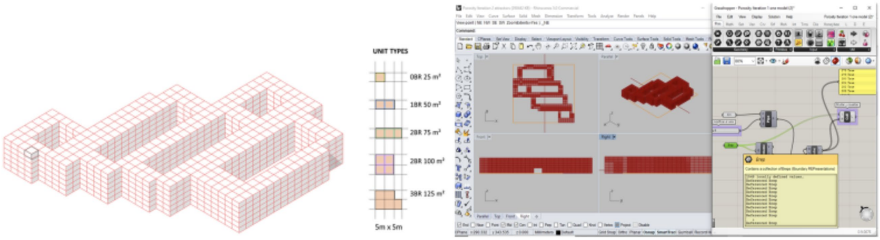

Figure 6. Generative design process. Source: (Author 2020)

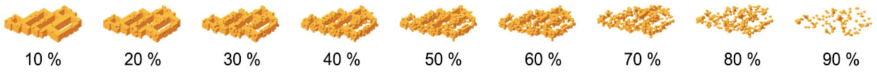

Figure 7. Mass porosity ratio from 10% to 90%. Source: (Author 2020)

defined as an optimum area per person. The combination of cells represents apartment units. Under the influence of prevailing winds, cells were subtracted to generate a 'porous' volume that allows cross ventilation. At a building scale, arranging void spaces as vents was conducted through data validation. With a random selection, 'cells were omitted from the geometry. After the development of a culling list, three components that take Boolean values (true/false) generate a list of 'selected' cells. These are subtracted cells from the massing. A ratio of porosity (10% to 90%) are controlled through 'slider components' that determine the percentage of reduction (Fig. 7). Through this step, 'diverting effect' was clearly seen between courtyards at ground level. In a subsequent step, prevailing winds were formulated as a 'generative vector' that based on its magnitude, direction and sense perforate the 'building volume'. So, cells intersected by this vector were omitted from the massing by determining the distance from it which are defined as 'area of influence'. These processes are oriented to displace, reorient, and re-scale iterations that can be analyzed through CFD simulations to reach a fitness proposal (Fig. 8). After outdoor CFD in IES-VE analysis and urban density study in Grasshopper, a model with 40 per-cent porosity was selected. Stronger airflow moving through the courtyards and apartments was observed that in more porous models. These void spaces of the building volume/ mass provide similar velocities across each one of the floors and units around a courtyard and enhance the interconnection of wind with their boundary. Also, this causes the increment of air exchanges in the units. Under this choice, the speed levels and outdoor temperatures in ground and first levels get similar to the values obtained from level 2 to level 4. Without less mass on top levels, openings influence a full flushing courtyards area that is dependent of having width to height rations larger than 2.4.

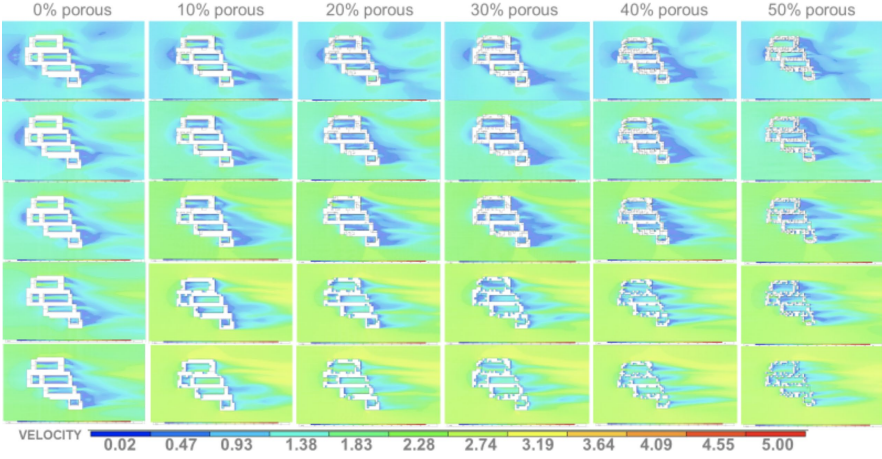

Figure 8. Porosity on massing via CFD analysis. Source: (Author 2020)

3. FINDINGS

Air flow and heat transfer processes occurring withing and around buildings were observed through CFD analysis. Specified boundary conditions (local climate conditions, internal energy sources such as people), surface temperatures of external walls were added for model accuracy.
Comparisons between baseline and proposed model through indoor temperatures, predicted percentage of dissatisfied and air changes showed that proposed courtyard building model reached the higher ventilation performance. Proposed model favors predominant westerly winds through mainly funnel and diverting effects when compared with the TOKI building. Indoor summer peak temperatures are lowered through building form, also operative temperatures are lowered corresponding to higher percentages of satisfaction. In terms of ventilation rates, 33% of improvement on ACH is obtained compared to the baseline model (Table 1).

Date	T (°C)		ACH		PPD (%)	
	B (Level 3)	P (Level 3)	B (Level 3)	P (Level 3)	B (Level 3)	P (Level 3)
May 17	22.8	20.8	1.8	2.46	6.7	6.3
Jun 14	22.3	21.2	4.6	9.6	10.5	9.3
Sep 21	23.1	21.7	2	3.96	9.3	7.7

Table 1. KPI comparisons on three selected days

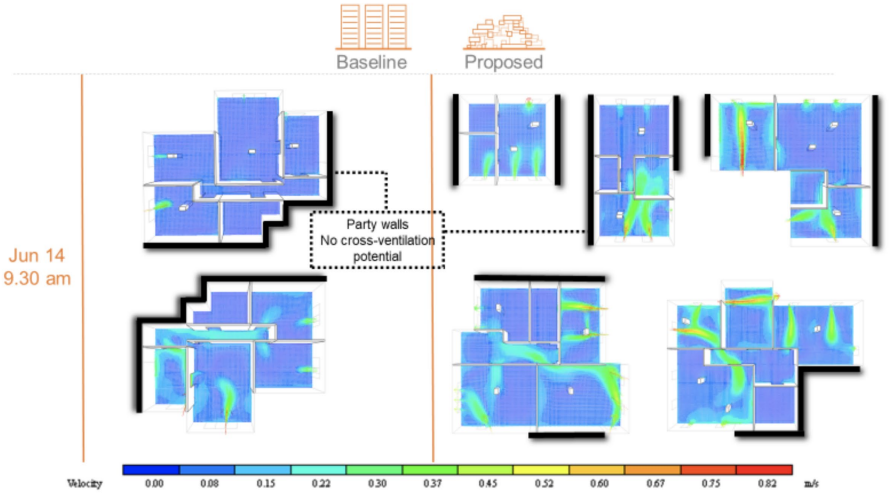

Figure 9. Comparison between baseline and proposed model on June 14th. Source: (Author 2020)

After external analysis, internal CFD simulations allowed to see airflow intensity and behavior in units. The TOKI project and the proposed model were compared on three selected days: May 17, June 14, and September 21. These days have the largest natural ventilation potential along summer. Among these months, June is the month when the velocity is the highest (Fig. 9). It affects cross ventilation inside units. Although airflow between rooms is observable in the TOKI southeast unit, all proposed units show higher performance. Overall, increased façade surfaces in the proposed projects make cross ventilation more effective in units. On the other hand, party walls in the TOKI projects prevent the cross-ventilation potential and limits rooms for only single-sided ventilation.This formula does not have any direct physical meaning but weighs the criteria following the

4. RESULTS

Under the analyzed case study, the conclusion of this paper is that the proposed typology is better by achieving various improvements and thermal comfort due to the application of cross ventilation. After outdoor and indoor analysis in different iterations, the 40 percent porous structure was selected. It provided a balance between urban density and air flow performance. Moreover, it has the potential to bring public housing closer to human needs and to the environment. Using renewable sources such as prevailing winds with the configuration of the new typology helped to alleviate thermal related problems in consonance with building forms derived from vernacular architecture in this region. Besides KPI's on natural ventilation, also urban density aspects are compared. Between projects, there is a difference of 11.2 square meter area per person. In TOKI model 13.8 square meter domestic pace per person increased to 25 square meters in the proposed case. Although number of people per hectare is slightly decreased in proposed units, multifunctional communal spaces have a potential of positive impact on this community.

CONCLUSION

This paper shows an improvement to the problematic presented in a public housing in Turkey. Lessons from vernacular architecture allow regulating harsh conditions of the climate. It proves the reformulation of well-known techniques can be still used for contemporary buildings. The usage of rule sets allowed to generate site-specific outcomes withing the context limitation, allowing the proposed model to take full advantage of and contribute to the environmental and connectivity characteristics of the surroundings. This generative approach resulted in a building mass calibrated towards environmental and social sustainability. The model based on courtyards shows a significant role in climate control and resident satisfaction. This model that is compelling enough with social aspects that were mentioned previously does not cause a stigma about social housing in the society. These are connection to the street, well-defined green areas, community spaces and different programs that will provide a sustainable solution for poorer communities.

PAPER #5.13

TUNING THE MASSES: CLIMATE SPECIFIC ENERGY OPTIMIZATION GUIDELINES

Alexander Mitchell[a], Tom Collins[a]
[a]Ball State University, Muncie, IN

ABSTRACT

In the United States, residential structures consume 21.5 quadrillion Btus annually--approximately 20% of the country's energy consumption-- and an equivalent percentage of carbon emissions. Most of these houses are not designed to be high performance buildings, and are built quickly to code minimums, where simple energy modeling programs, Res-Check for example, validate compliance. The goal of this project is to create an easy to use, accessible, and open-source framework to improve building performance specifications in the schematic design phase, with the goal of complying with a high-performance building standard.
Programs such as Department of Energy's (DOE) Zero Energy Ready Homes (ZERH), and LEED for Homes aim to offer simple, prescriptive checklist design methodologies, while organizations like Living Building Institute and PHIUS offer performance-based programs that can require the expertise to achieve their standard, and in PHIUS' case require a specific, costly compliance software. There needs to be an option that helps bridge the gap, in terms of being open source and more accessible to non-specialists.
By using direct search optimization methods, this study developed a tool to determine residential energy benchmarks to enable designs to meet high performance standards such as PHIUS. these are determined through thousands of iterations on ten different house geometry typologies in the nineteen distinct climate zones in the United States. These newfound limits on performance ranges get a new, climate specific script that will tune a mass, and provide the designer with simple, project geometry and climate-distinct building specification to incorporate into the building's design.

KEYWORDS

Optimization; energy modeling; climate responsive design; parametric modeling.

INTRODUCTION

Building performance standards and codes are dominated by points systems that may or may not actually produce higher performance buildings. A limited number of these standards are performance based, where the standard is based on an energy consumption target, such as PHIUS, PHI, or LEED. These are relatively complicated standards to meet and require energy modeling to meet these standards. Designers of high-performance houses are increasingly moving away from prescriptive design standards and toward system that rely on modeling to prove performance that meets energy use targets. These methods require special software and skills, as such, are beyond the reach of non-specialists interested in understanding whether a building form can meet high-performance standards
Performance based tools allow for building energy optimization. These types of programs and methodologies allow for the design team to evaluate many options in terms of enclosure, glazing, mechanical system, lighting and domestic water heating, and compare them to a series of output metrics such as carbon emission production, cost of higher end insulation and systems,

and energy consumption- in both energy (i.e. Btus) and monetary value. One way that energy performance modeling tools differ from prescriptive energy efficiency methods is that they are based on a specific building geometry (shape) modeled in specific climates or locations.

Optimizing a building's performance specifications through an energy model increases the quantity and quality of possibilities for achieving high performance outcomes. The performance-based tools, especially those running iterative parametric optimizations, create multiple options that can meet the design criteria. But this tool is frequently reserved for qualified professionals, and it is not accessible to most people working on home building projects. Approximately two percent of American houses are designed by architects (Conroy 2007), compared to those designed solely to be the contractor or built from a set of available plans. Herein lies the goal of this project, to make a simple, climate-specific optimization tool that almost anyone can run on a pre-designed 3D mass. This allows for architectural flexibility, whether the project is a new and fanciful architectural design, or a simple spec home from a pattern book or set of hardware store plans. These geometries, or house forms, can be input into the script and get sets of building performance specifications as feedback on the design. Many contractors have the form in mind already, but just lack the tool set to determine the building performance specifications to design to high performance building standards.

There are some assumptions built into the design tool, based on practices are conventional and have worked well in the past. When challenging and building norms, it is important to provide references for the revised idea. The tool will be provided with a supplemental user's manual, which includes instructions for using this optimization framework, some collected anecdotes about best high performance home design practices, and some details that may be handy when it comes to applying the newly created building performance specification to the final built house.

Climate specific standards are critical in terms of high-performance home design, because an understanding of how the building interfaces with the climate that has the largest impact on the building's overall energy performance. The more tuned a building is in form, materiality, and passive strategies, the less energy it will consume, especially for space conditioning (Olgyay 2015). In this paper we will describe the development and pilot testing of a new tool for climate specific housing design guidance. The pilot study tested one specific climate zone as a precursor to the final tool, which will include all climate zones in North America.

1. METHODS

Climate specific building envelope specs started in the 1970s in the United States and have been greatly developed by organizations like PHIUS, and that PHIUS+ now represents the gold standard. These strategies are all based around energy conservation as the first step, and meeting the remaining loads with smaller, highly efficient mechanical systems. Therefore a standard based around passive design principles first will likely need a few different methods of rating the buildings, and in the case of the PHIUS+ criteria, there are three key pillars: heating and cooling demand limits, a source energy limit for all building energy consumption, and a prescriptive airtightness requirement. This creates a standard that requires some complicated modeling in order to comply with the goals and may be less accessible to all homebuilders. A defining feature of the PHIUS criteria is that it is climate specific. Every project complies with the PHIUS+

criteria is built to these climate specific criteria (Klingenberg, 2015).
The US Department of Energy's Building America Program, and the resulting Zero Energy Ready Homes (ZERH) standards provide much of the prescriptive minimums for the PHIUS+ guidelines. Like the more rigorous PHIUS+ guidelines, the ZERH is focused on energy conservation methods first, by setting an airtightness minimum, and climate zone specific minimums of the thermal performance of the building enclosure. As this program is purely prescriptive, there is no complicated modeling compliance. This is likely due to a goal to saturate the market with the standards, while PHIUS standards prove to be more niche.

2. HYPOTHESIS

This pilot study poses three hypotheses. First, greater amounts of thermal insulation are required for climates with more heating degree days. Second, compact geometries with less surface area use less energy than complex geometries with more surface area. Third, houses with more southern glazing perform better than houses with more southern glazing in Chicago's cold, humid climate.

3. ANALYSIS

To test and determine the appropriate ranges of input specifications for the Chicago, USA pilot study climate zone, 11,520 modeling iterations were performed to create a broad spread of data to analyze and parse through. Chicago was selected due to its large number of households, potentially yielding a large impact, and the climate is one of familiarity to the authors. The modeling methodology described below has been performed for this climate zone only and will be continued for six additional climate zones with few revisions for the furthering of this study. The refined data will be built into the resulting design product, a climate specific optimization script for any single-family residential structure in that climate zone.

4. METHODS

The parametric modeling for this study was performed in multiple stages in order to ensure the lack of errors that potentially occur from the design of the study or the myriad of software utilized and to allow for parallel computing on multiple machines. Based on the study of existing, built high performance homes, it can be understood that an energy conservation first approach, with efficient mechanical systems to meet the reduced loads is a clear and direct path to higher performance homes. This conservation first method relies on some of the understood best building science practices, with simulation of specific elements to create a refined design. For this study, the enclosure was the focus of this load reduction first study, and the wall insulation value, roof insulation value, window thermal resistance, and window to wall ratio of the glazing on each of the four orientations creates seven variables, with the house geometry as the eighth.
The building massing models were drawn using the Rhinoceros 3D modeling program, and then using Ladybug, Honeybee, and Colibri, plugins for the Grasshopper parametric design interface for Rhinoceros, the variables were iterated and IDF files, the input document for the EnergyPlus simulation engine were written. Originally, the simulations were to be performed directly using the Honeybee plugin to communicate with EnergyPlus, however this proved to be error prone and time consuming, so EnergyPlus was used in its native format for the remainder of the study. It is important to note that all PHIUS+ compliance is

done solely through the WUFI energy simulation engine, so EnergyPlus would not be permitted for compliance. However, the PHIUS+ targets were determined using BEopt, a platform that uses EnergyPlus as the simulation engine.

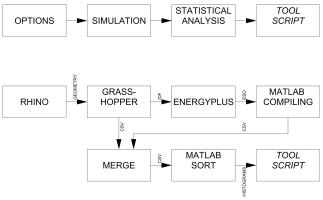

Figure 1. Flow chart detailing the overall process for the study. The top flow chart represents the overall flow of the study, while the bottom details the software used and interactions between programs.

4.1. Geometry and Grasshopper script

Five different home geometries were selected to create a variety of inputs for the study (see Fig. 2). The aim of this variable is to ensure the results are not a climate-specific response to only one house shape. The five house types selected are based on common American housing forms and are as follows: T-1 two story Georgian, T-2 two story foursquare, T-3 ranch, T-4 craftsman bungalow, T-5 L-shaped gable. See Figure 1 below. These were modified to all be approximately 204 m2 (2200 sqft) to meet the benchmark size from the US Department of Energy's Zero Energy Ready Homes (ZERH) program for a three-bedroom home (DOE 2019).

4.2. Variables Iterated

Four of the five home types are modeled with three thermal zones with the first floor, second floor, and unconditioned attic each separated out for ideal air load analysis, as most two-story single-family homes are split into zones by floor. The ideal air load analysis is to allow for the selection of an efficient mechanical system later in the design process and focus on tuning the passive space conditioning loads to start. The T-3 ranch house was split in half to create two thermal zones (a public and private wing of the house) as this style is typically a one-story house layout. The occupiable zones then had parametrically determined window to wall ratios applied on all four orientations in 0.10 (10%) increments. East and west facades were eligible for 0.10 and 0.20 options, the north 0.10, 0.20, and 0.30, and the south could have 0.10, 0.20, 0.30, and 0.40 as the window to wall ratio. All windows matched the same performance specification, and the southern windows had shading overhangs determined automatically through a script based on the tuning point of the solstices, as to wholly shade a southern

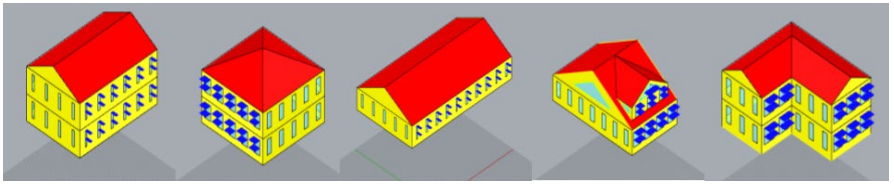

Figure 2. House types, from left to right: 1. Georgian, 2. American Foursquare, 3. Ranch, 4. Bungalow, 5. L-Shaped Gable. These were selected for their diversity of shape and orientation and are commonly found across the United States (Howe 2002).

facing window at noon on the solstice. This practice is commonly recognized as a good starting place for shading overhang design (Kwok 2018).

Windows for the Chicago pilot study all had a Solar Heat Gain Coefficient (SHGC) of 0.50 and a Visible Transmittance (VT) of 0.70, from the PHIUS Climate-by-Climate Recommendations for Window Performance (PHIUS 2019). The houses were modeled with three different window U-Factors: 0.568 W/m2 K (0.10 Btu/hr ft2 °F), 1.703 W/m2 K (0.30 Btu/hr ft2 °F), and 2.839 W/m2 K (0.50 Btu/hr ft2 °F) for the entire window assembly, including the frame. The houses were modeled different opaque wall U-factors: 0.284 W/m2 K (0.05 Btu/hr ft2 °F), 0.189 W/m2 K (0.033 Btu/hr ft2 °F), 0.114 W/m2 K (0.02 Btu/hr ft2 °F), and 0.071 W/m2 K (0.013 Btu/hr ft2 °F). These assemblies were modeled with the insulation as a no mass material sandwiched between a 13 mm (0.5 in) layer of gypsum board on the interior and 25 mm (1 in) of stucco on the exterior to add a slight amount of thermal mass to the wall, to more accurately resemble typical building assemblies. The houses were modeled with different roof assembly U-factors: 0.071 W/m2 K (0.033 Btu/hr ft2 °F), 0.284 W/m2 K (0.05 Btu/hr ft2 °F), 0.071 W/m2 K (0.013 Btu/hr ft2 °F), and 0.057 W/m2 K (0.01 Btu/hr ft2 °F). Each of these assemblies was also equipped with the 13 mm (0.5 in) gypsum board on the interior for some thermal mass. These houses were modeled with cold roofs, where the insulation is at the ceiling of the highest occupiable space in the building. The airtightness of the of the house has been kept constant at 0.0002 m3/s per m2 (0.039 cfm/ft2), and the slab on grade modeled as a 100 mm (4 in) concrete slab with insulation underneath, for a total assembly U-Factor of 0.278 W/m2 K (0.05 Btu/hr ft2 °F), representing a reasonable building construction and airtightness compliant with the PHIUS+ 2018 requirements.

4.3. Energy Simulation and Data Analysis

With the input variables of the simulation defined above, the output metrics considered are ideal air loads for annual heating and cooling energy, normalized per building area, or *EUI*, and the total insulation R-Value in the house normalized per the respective enclosure area. This total insulation factor is labeled *R- Points* and is used as a cost and embodied carbon analog. In a more advanced study, cost and embodied carbon of the building enclosure can be computed, but as this is an early analysis tool, these specific enclosure assemblies have not necessarily been decided yet.

The IDF files written by the Grasshopper script were then computed on multiple machines to batch run in EnergyPlus, allowing for four simulations to run simultaneously on one single machine, and save time compared to the previous method in data storage. To compile the 11,520 iterations' output files, a MATLAB, a numerical programming environment, script was written. Then, the resulting data was compiled into a larger spreadsheet including the input variables.

4.4. Data Sorting

A second MATLAB script sorts through this data and prompts the user for the upper heating and cooling limits, and the total number of *R-Points* permitted. The space conditioning limits are determined by the PHIUS space conditioning criteria, and the *R-Point* limit is lowered to find the range of the 10% of compliant options. This script filters the data that is beyond the set range allowances and creates a new table with the parsed data including the total number of the iterations after the limits are applied. These represent the high-performance options in that climate zone. The MATLAB function

fitensemble was used to apply an ensemble of learning regressions to the data that provides the user with a table that describes the importance of each input variable to the user. Histograms of the input parameters are also plotted, to detail the frequency of occurrence of the input variable. This is the determining factor of what ranges the input variables will be used in the *tool script*.

5. RESULTS

Although writing EnergyPlus IDF files, running the simulations, and aggregating the data is quite time consuming, analyzing the results was relatively quick by comparison. The resulting data provided the modified input ranges for guidance as to where to put the limits on their energy optimization script, or the *tool script*.

5.1. Setting Limits

Limits on energy consumption can come from many sources, but for this pilot study, the annual heating demand and annual cooling demand from the PHIUS Space Conditioning Criteria Calculator has been used (PHIUS 2018). For the 204 m2 (2,200 ft2) homes used in this pilot study with an expected occupant load of four occupants, the calculator provides the performance specification for compliance with PHIUS+ 2018 standard. For the Chicago climate shown, the annual heating demand limit and annual cooling demand limit are 31.6 kWh/m2yr (10 kBtu/ft2yr) and 34.7 kWh/m2yr (11 kBtu/ft2yr) respectively. These are entered when prompted by the data sorting MATLAB script along with a R-8.8 m2K/W (R-50 ft2 °F h/Btu) normalized *R-Point* limit. The result is a table that has 1,057 iterations remaining, approximately 10% of the total iterations. The aim here is to determine buildings that are compliant, yet do not require excessive insulation, typically resulting in higher costs and higher embodied carbon.

5.2. Variable ranges

The remaining 1,057 iterations have been analyzed for variable importance, with the window thermal resistance, wall insulation value, and house geometry (in that order) showing dominance in effect on the space conditioning energy demand. These ranges are then used to influence a second, climate specific script to optimize homes for that climate zone. These input ranges represent the best practices in the climate zone, specifically the representative city, and confirm existing knowledge and other studies examining passive building strategies approaching the point of diminishing returns. These ranges are plotted on histograms shown in Fig. 4,5,6,7.

Based on this pilot study and across the input variables given, buildings meeting the early design PHIUS threshold have 0.189 W/m2 K (0.033 Btu/hr ft2 °F) to 0.114 W/m2 K (0.02 Btu/hr ft2 °F) walls, 0.071 W/m2 K (0.033 Btu/hr ft2 °F) to 0.071 W/m2 K (0.013 Btu/hr ft2 °F) roofs, well insulated windows and a minimal amount of glazing. While this study aims to be geometry agnostic, it is important to note the histogram for the house type. There are no house type 3's in the results, and a strong showing of house type 4's, with house type 3 as the ranch house, and house type 4 as the bungalow. This is likely a factor of the compactness of the bungalow relative to the other designs, and the ranch having the highest surface to volume ratio in this housing geometry selection, which is a strong driver of energy consumption, especially in heating dominated climates like Chicago. This means that none of the ranch house geometries met the limits in the statistical analysis.

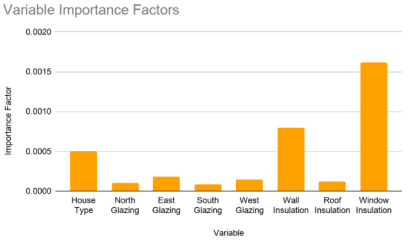

Figure 3. Chart depicting the relative importance of the different input variables for Chicago, IL. The primary factors on space conditioning for this climate are window insulation, followed by wall insulation and then house type, or building geometry.

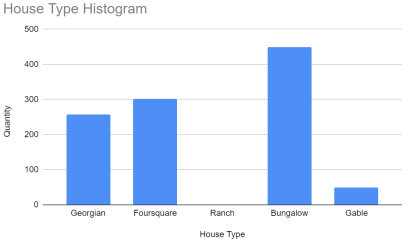

Figure 4. House type histograms. The resulting count of house geometries present after limiting the results. Note that there are no ranch houses that met the limits set. The strong presence of bungalow geometry confirms the advantage of a compact enclosure area.

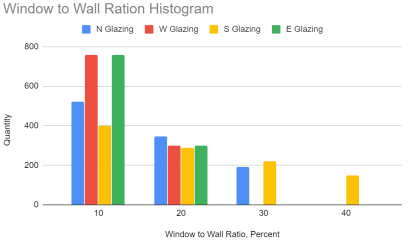

Figure 5. Window to wall ratio histograms. Note the strong trend towards lower glazing areas on all facades.

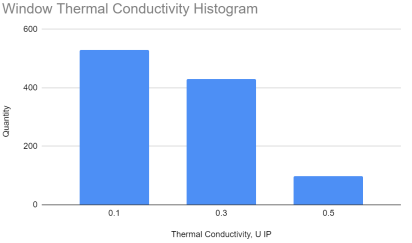

Figure 6. Window U-factor histograms. The lower the U-factor, the greater the prevalence. This confirms the PHIUS specifications about window U-factors. It also ties in with the high importance of window insulation relative to other aspects of the building.

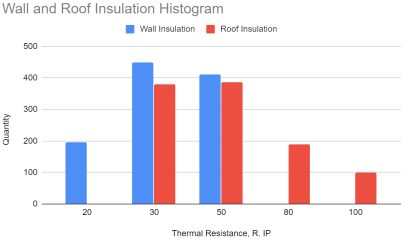

Figure 7. Histograms corresponding to the wall and roof insulation types. There is the hypothesized bell curve forming around R-30 walls and R-50 roofs.

5.3. Regression Analysis

A fitness ensemble of regressions was applied to the data as well and determined that the most important variable in the design is the window insulation, followed by the wall insulation, followed by the overall building geometry, see Fig. 3. The window ranges for this pilot study are likely to be a little high compared to the ranges of windows installed on most residential structures as the ZERH guidelines recommend that the window to wall ratio does not exceed 15% (DOE 2019).

5.4. Resulting Script

The result of this direct search optimization is a climate specific script to tune residential structures for a specified climate zone. In the case of this pilot study, that climate zone is ASHRAE 5A, Chicago, IL. Based on the resulting histograms, Fig. 4-7, the input variables were pared down for this climate. The house geometry variable is eliminated, as this script takes in user defined geometry. East and west glazing are limited to 10%, being a built-in factor in the script. North and south glazing are left with the options of 10% and 20%, so there are two options in each of those spots. The wall insulation is varied in two options, 0.189 W/m2 K (0.033 Btu/hr ft2°F) and 0.114 W/m2 K (0.02 Btu/hr ft2 °F), and the roof three options, 0.071 W/m2 K (0.033 Btu/hr ft2 °F), 0.284 W/m2 K (0.05 Btu/hr ft2 °F), and 0.071 W/m2 K (0.013 Btu/hr ft2 °F). Windows were also limited to two options, 0.568 W/m2 K (0.10 Btu/hr ft2 °F) and 1.703 W/m2 K (0.30 Btu/hr ft2 °F), with the constant SHGC of 0.50 and a VT of 0.70. Three roof options, two wall options, four glazing options, and two window options results in 48 variations for the input house to be varied through, and based on an approximately 45 sec runtime per variation, the user can have 48 options, the majority of which are likely compliant with the PHIUS+ 2018 criteria in 36 mins.

CONCLUSION

Even though this is only a pilot study, the resulting script or *tool script* is developed. The pilot study will inform the development and refinement of the finalized script that includes a wider range of climate zones. At this point, the ability for the user to input any geometry for a residence of their own design, and get quick options that would comply with the rigorous PHIUS+ 2018 standard should prove valuable, especially in the early design phases. The results provide options that would comply with standards such as PHIUS+ 2018, but also the total number of results that comply with the standard is a good indicator as to how well the geometry alone performs. Out of the 48 iterations in the current *tool script,* a well-designed building geometry would have a majority, say 36 (75%) of the iterations return with a compliant result. A less efficient shape, maybe with a low compactness ratio would likely have less compliant results, or perhaps none. When further developing the *tool script*, it would be wise to have this information including the surface to volume ratio displayed as feedback on the design. The data from this pilot indicates that the script developed can provide useful information to users about the potential of their design idea (as represented by a massing strategy) to meet high-performance standards.

Future Work

Further studies are to be done in six more climate zones, to build a library of these tools to aid in the design to PHIUS+ 2018 criteria around the United States. However, before expanding out, a few things should be looked at further within this study. Primarily, it would be wise to have more finely graduated steps in the variables, for better accuracy. For example, maintaining the current spread of variation in wall assemblies, but having seven options instead of the mere four done in this pilot study. The ranges of window to wall ratio should be adjusted as well, moving the south from 10% to 40%, to a range of 5% to 25%, in 5% increments. These window to wall ratios would better align with the common residential construction done currently and follow the ZERH guidelines. It would also be worthwhile to test this method using energy simulations other than EnergyPlus, to see if that influences the results, as other engines like TRNSYS and WUFI handle some

building physics aspects differently. This study focuses on North American climate zones, but can be expanded internationally, as many of the climate zones in the world are represented by and analog in North America. A graphic, user-friendly interface would be developed to ensure accessibility for all users.

PAPER #5.14

THERMAL PERFORMANCE OF A NOVEL MASONRY BLOCK MADE FROM RECYCLED GYPSUM DRYWALL WASTE.

David Drake[a], Taiji Miyasaka[a]
[a]Washington State University, Pullman, WA USA

ABSTRACT

Developing new product applications for waste recycled from building construction and demolition (C&D) provides environmental and economic benefits. However, challenges remain for recycling certain low-value C&D materials, such as gypsum drywall waste, which is banned from landfilling in some areas due to hydrogen sulfide emissions during decay. The gypsum and paper components in drywall have low thermal conductivity relative to concrete and brick, suggesting a novel insulative masonry block system made from recycled gypsum drywall waste could have higher thermal performance than conventional concrete masonry units (CMU). The authors have developed such a system, referred to as Drywall Waste Block (DWB), and have previously published investigations of DWB engineering properties including compressive strength, water absorption, bulk density, and thermal conductivity. This paper describes investigation of resistance to heat flow of a reinforced DWB wall assembly, using a calibrated hot box apparatus as specified in ASTM C1363-11. The hot box apparatus was designed and fabricated as a cost-effective alternative to commercially testing services, affording rapid iteration during the research and development phase of novel building products made from unconventional materials. Some aspects of the apparatus design, fabrication, and characterization are discussed. Thermal performance of the DWB wall relative to a comparable CMU wall is discussed, as are areas for further research.

INTRODUCTION

Industry studies show waste from building construction and demolition (C&D) is a growing problem (US EPA 2016) and that recycling C&D waste provides many environmental and economic benefits (CDRA 2017). Challenges remain for recycling some C&D waste materials, including gypsum drywall waste, which has limited uses and low value as a recycled commodity (CDRA 2017) (King Co. 2017). Lack of demand for recycled drywall waste is a barrier to increased recycling (Lederman 2015). Drywall waste recyclers have unused capacity, and would like new markets for recycled drywall products (CDRA 2017) (King Co. 2017). To divert increased amounts of waste from landfills, new applications for recycled drywall waste need to be developed and brought to market.

The authors have developed proprietary mixtures and methods for producing a masonry block system that utilizes recycled gypsum drywall waste. Previous investigations have shown these Drywall Waste Blocks (DWB) approach ASTM compressive strength and water absorption standards for conventional concrete masonry units (CMU), with lower density and lower thermal conductivity than CMU.

However, the construction industry is typically slow to adopt new building products in the absence of demonstrated cost and performance advantages (Sorrell-Neal 2018). Processing drywall waste for DWB production is simpler than other drywall recycling methods, and DWB can be manufactured using standard CMU machinery and curing methods. Therefore, cost-per-unit is expected to be competitive with CMU. Establishing superior performance vs. CMU in the area of thermal performance may further adoption of DWB, increase recycling of gypsum drywall waste, and divert more drywall waste from landfills.

Gypsum drywall panels consist of a gypsum core (calcium sulfate dihydrate: $CaSO4•2H2O$) sandwiched between paper facing and backing layers, and are widely used as an interior finish material in both residential and commercial construction (Crangle 2018). Drywall is inexpensive, relatively easy to install, and inherently fire resistant. However, installation methods produce significant waste during construction, typically 10-12% of installed material (Crangle 2017).

Where permitted, drywall waste is usually disposed of in municipal landfills. In 2016, the most recent year for which figures are available, some 8.8 million tonnes of drywall waste were landfilled in the United States alone, approximately 9.1% of the landfilled waste from building C&D (CDRA 2017). Under anaerobic conditions common in landfills, decaying drywall waste emits hydrogen sulfide gas ($H2S$). At low levels, $H2S$ is detectable as an offensive 'rotten-egg' odour, and has health impacts at higher concentrations. Landfilling drywall waste from construction is now banned in some locations (Lederman 2015), (King Co. 2017).

Methods for incorporating drywall waste in building materials have been reported in literature, including use of recycled gypsum drywall waste as a supplemental cementitious binder in concrete (Naik 2010), and use of gypsum drywall waste as a binder in controlled low strength materials (Raghavendra 2015). Cited benefits of incorporating drywall waste in new building materials include reducing $H2S$ emissions associated with landfilling, and substitution of waste-derived binders for Portland cement, reducing energy use and $CO2$ emissions.

Gypsum has inherently lower thermal conductivity than both Portland cement and conventional concrete aggregates (Asakura 2013). Investigation of insulating composites of gypsum and natural and artificial fibres have been reported (Belayachi 2016), (Mounir 2015). Previously published investigations of DWB engineering properties found thermal conductivity for a homogeneous sample of DWB material to be as low as 0.149 W/mK, well below the range for typical concrete and brick masonry (Drake 2019). Because masonry wall construction is typically heterogenous, thermal performance for a heterogenous wall assembly is often lower than measured performance of a homogenous specimens.

ASTM 1363-11 describes procedures for investigating resistance to heat transfer of wall assemblies by means of a hot box apparatus, including schematic designs and performance parameters for such an apparatus. Hot box testing by certified test facilities have lead- and turn-around times complicating rapid iteration of preliminary investigations, and can be prohibitively expensive (Seitz 2015). Nor is there a commercial supplier of lab-scale hot box apparatus. Facilitating further investigation and optimization of DWB wall assemblies required the design and fabrication of a cost-effective hotbox testing apparatus, meeting ASTM 1363-11 standards where practical.

There are few published reports of design and fabrication of an affordable, lab-scale hot box testing apparatus. Seitz and MacDougall report successful construction, commissioning and characterization of such an apparatus, and its initial use to test plastered straw-bale wall sections (Seitz 2015). Costs of $37,135 CAD are reported for

the completed apparatus, including $9,135 CAD for construction materials, sensors, and data acquisition. The reported design is not self-contained, relying on enclosure of the entire apparatus in an environmental chamber. Metering wall plus flanking losses between 94-96% of total heat input to the hot box are reported, likely due to the temperature differential between the metering chamber and the climatic chamber being identical to the differential between metering chamber and ambient temperature surrounding both chambers.

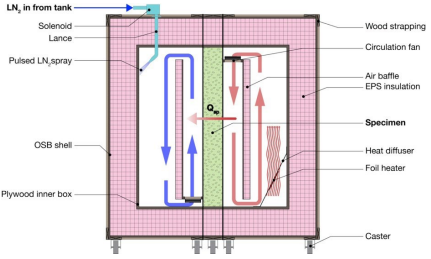

Figure 1. Schematic diagram of calibrated hot box as constructed, with heating, cooling, and air circulation systems, typical air flows in the chambers, and heat flow through the specimen, Qsp.

1. MATERIALS AND METHODS

1.1. Hot box apparatus design and fabrication

Figure 1 illustrates the calibrated hot box apparatus designed for investigation of DWB assemblies. The apparatus accommodates specimens approximately 1.5 m¬2, the minimum area required by the ASTM standard, and consists of two temperature-controlled chambers: a metering chamber ('hot' side), held at typical indoor temperature (i.e., 21° C); and a climatic chamber ('cold' side), controlled to simulate a range of outdoor temperatures. When separated by a test specimen, measurement of power required to maintain hot side temperature can be used to derive surface-to-surface thermal resistance, R, to heat transfer through the specimen, Qsp, provided the temperature of both chambers can be held in narrow bands around respective set points, and that heat transfer along other paths is understood and minimized. Determining metering chamber heat flow corrections is accomplished by characterizing the hot box apparatus with a specimen of known resistance.

To reduce error, heat lost through the metering chamber walls, Qmw, and flanking losses around the edges of the specimen, Qfl, is designed to be a small fraction of Qsp; the ASTM standard is ≤ 10%, with 1-2% preferred (ASTM 2018). This can be done by keeping the chamber wall area small, insulating the walls of one or both chambers to keep resistance to heat flow high, and minimizing or eliminating the temperature differential between metering chamber and ambient lab temperature. Noting the loss percentages reported by Seitz and MacDonald, it was determined a self-contained design would offer the best control of temperature differentials.

Chamber construction. Hot and cold side chamber inner walls are 19 mm plywood, painted with flat grey acrylic paint for emissivity > 0.8. Air circulation baffles in each chamber are 6 mm medium density fibreboard (MDF), insulated with one 51 mm layer of Type 1 expanded polystyrene foam (EPS). Chambers walls are insulated with four layers of 51 mm Type 1 EPS, bonded with polyurethane glue, seams offset and taped to minimize air leaks. Chamber apertures are gasketed with 16 mm closed cell foam. An outer wall of 11 mm oriented strand board (OSB) reinforced with 19 mm plywood strips protects EPS insulation and provides a mounting surface for hardware and controls. Test specimens are installed in an insulated frame constructed in the same fashion. During operation, the framed specimen is clamped tightly between the two chambers by means of adjustable-tension draw latches

attached around perimeters of the chamber apertures and the specimen frame.

Heating and cooling systems. Metering chamber heat source is a 205 W / 120 VAC foil resistance heater, attached to a galvanized steel heat diffuser located behind the air baffle. The climatic chamber is cooled by pulsing liquid nitrogen (LN2) from a low-pressure tank (~172 kPa) through a thermostatically-controlled solenoid valve. LN2 is used rather than mechanical refrigeration due to lower up-front costs. Both chambers are equipped with four 1.44W computer fans for air circulation.

Instrumentation. Electronic Innovations EI1022 temperature sensors (operating range -40°C—110°C; accuracy ±1° C) are installed in the air circulation paths of each chamber for thermostatic control of heating and cooling systems. An additional EI1022 sensor, shielded to minimize effect of air currents, is installed near the outside surface of the metering chamber to monitor ambient lab temperature. Specimen temperature is monitored with nine Texas Instruments LM34CAZ temperature sensors per side (operating range -17°C—110°C; accuracy ≥ ±1°C), arranged in an evenly-spaced grids. Grids of four LM34CAZ sensors are installed on each air baffle, facing the specimen. The metering chamber exterior wall is instrumented to act as a heat flux transducer using 42 thermocouple junctions (T-type, 24 gauge, special limits sensitivity), alternating between inside and outside of metering chamber and connected in series. All sensors are attached to surfaces with foil tape topped with black duct tape to increase emissivity.

Controls and data acquisition. A LabJack T7Pro data acquisition and control module, expanded to 56 input channels with LabJack Mux80 multiplexer and two LabJack CB37 terminal boards, is used for all monitoring, controls, and data acquisition. A LabJack RB12 relay board with Opto22 relay modules is used to pulse power to the LN2 solenoid valve and heater. Kipling3 software is used for configuration and custom Lua scripting. LJLogM software is used for data acquisition and recording. Data logging interval is 100 ms, averaged and recorded every two seconds.

Expenditures. Final costs for the hot box apparatus were $15,823 USD, of which $3,900 USD was for construction materials, cooling, heating and air circulation systems, instrumentation, and data acquisition; and $11,923 was for fabrication and commissioning labour. The LN2 lockset tank is rented for $30 USD per month, and cost of LN2 is $1.10 USD per liter.

1.2. Hot box apparatus operation

Minimum test run duration. To establish a minimum duration for test runs (outlined in ASTM C1363-11 sec. A10.3), a 3 mm MDF panel was installed in a specimen frame, instrumented, and sealed with self-adhesive polyethylene plastic film and tape to minimize air permeability. Real-time monitoring using LJLogM software was used to determine when the system reached initial steady-state, (i.e., hot and cold side temperature sensors stable around respective setpoints, with no more than ±0.5° C fluctuation, and calibrated panel and baffle sensor readings within ± 1°C of each other), and when the system returned to steady-state following a 1°C change in the climatic chamber set point. Time to return to steady-state following perturbation was found to be ≤ 10 minutes. Although a so-called 'time constant' calculated according to the ASTM standard would be shorter than the time to return to fully to steady-state, it was decided characterization test runs for a minimum of 60 minutes following initial steady-state were practical and exceeded the ASTM standard of six consecutive time constants.

Characterization. A characterization panel of 1219 mm x 1219 mm x 153 mm was constructed using three layers of 51 mm Type 1 EPS foam. The panel was mounted in the specimen frame, and instrumented and sealed as above. Once operating procedures were established, a total of five characterization

Test No.	t_h (°C)	t_c (°C)	Δt (°C)	t_a (°C)	Q_h (W)	Q_f (W)	Q_{aux} (W)	Q_{cp} (W)	$Q_{(mw+fl)}$ (W)	$Q_{(mw+fl)}/Q_{aux}$ (%)

t_h: panel surface temperature, hot side; **t_c**: panel surface temperature, cold side; **Δt**: temperature differential (t_h - t_c); **t_a**: ambient lab temperature; **Q_h**: heater power input; **Q_f**: fan power input (from manufacturer's data); **Q_{aux}**: total power input (Q_h + Q_f); **Q_{cp}**: heat flow through panel; **$Q_{(mw+fl)}$**: heat flow through metering chamber wall and around panel (Q_{aux} - Q_{cp}).

Table 1. Characterization panel results

tests were performed, at nominal temperature differentials of 35°C, 30°C, 20°C, 10°C, and 5°C.

Characterization test runs are summarized in Table 1. Heat flow through characterization panel, Qcp (W), is calculated using:

Equation 1.

$$Q_{cp} = \frac{A \bullet (t_h - t_c)}{R}$$

Where A (m2), is the characterization panel area, th and tc (°C) are temperatures of panel hot and cold sides, and R (K m2/W), is resistance to heat flow of the panel per manufacturer-supplied data. For the EPS panel used to characterize the hot box apparatus R = 4.5 K m2/W.

Heater power input to the metering chamber, Qh, is calculated by taking a one-minute moving average of on/off time as recorded by the data acquisition model and multiplying by heater power, Wh, for the length of time heat balance within the system is observed in steady-state.

1.3. Waste block materials and methods

Mixing, forming, and curing. Gypsum drywall waste (GW) was sourced from local building construction and demolition sites, and included a typical variety of types and thicknesses. Demolition waste tested negative for asbestos (third-party certified lab). Waste drywall boards were reduced to convenient size by manual breaking, then pulverized using a hammer mill equipped with 5 mm screen (Figure 2a).

Blocks measuring 75 mm x 305 mm x 153 mm were formed on a custom-made hydraulic block press (Figure 2b), at formation pressure of 7.6 MPa, resulting in block dry density of approximately 1.2 g/cm3 Blocks were cured for seven days covered with polyethylene sheet, followed by ≥ 56 days of drying at ambient lab temperature and humidity.

A single-wythe DWB wall section measuring apx. 1219 mm x 1219 mm x 153 mm was constructed, consisting of 15 courses of block, mortared with 7 mm joints of Type S mortar (ASTM C270). All cores were fully grouted with fine aggregate grout meeting ASTM C476-18, and the two perimeter cores were reinforced with nominal 13 mm steel reinforcing bars (1070 mm on centre). The assembly was allowed to cure and dry for ≥ 28 days at ambient lab temperature and humidity before mounting in specimen frame for testing (Figure 3).

A series of five tests were conducted, at nominal temperature differentials selected to match characterization conditions. Due to lower ambient lab temperatures and sensor sensitivity limits, actual differentials were less than for characterization tests.

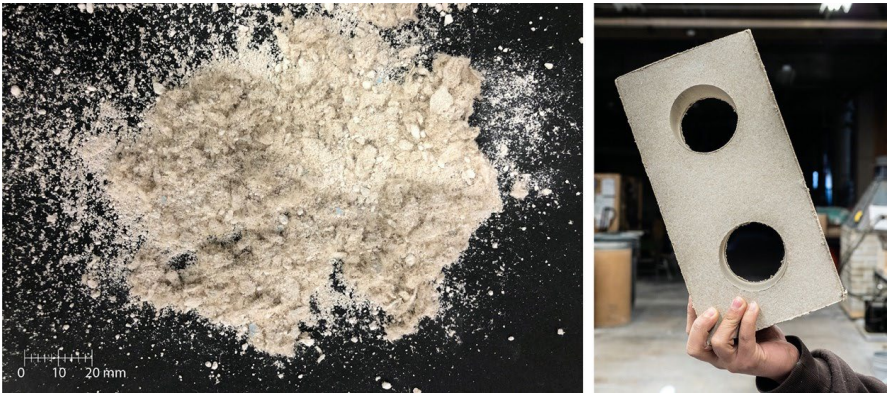

Figure 2a. Shredded drywall waste from demolition; Figure 2b: prototype DWB masonry.

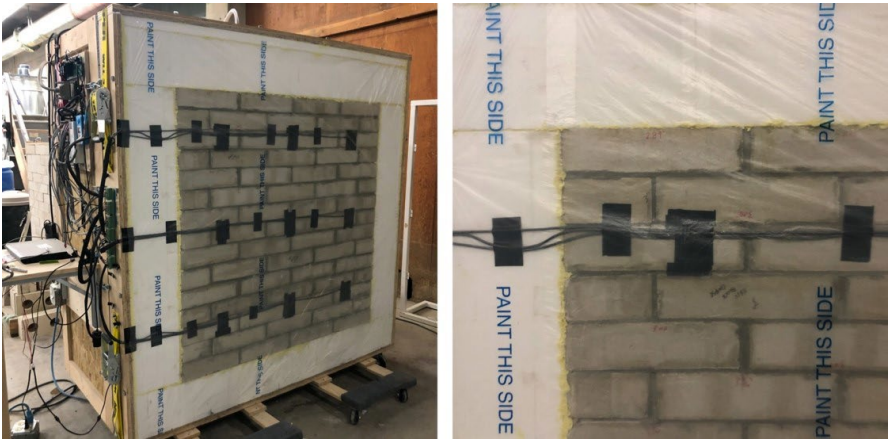

Figure 3a. DWB specimen wall prior to testing. Figure 3b: Wall detail. Wall has been instrumented, mounted in frame, and frame is clamped to climatic chamber.

2. RESULTS AND DISCUSSION

Results from DWB specimen test runs are summarized in Table 2. Note these test runs were conducted on the same DWB specimen wall, with the variables under examination being the temperatures of specimen hot and cold sides (th and tc), and the consequent temperature differential between them. Resistance to heat flow, R (Km2/W), is calculated using:

Equation 2.

$$R = \frac{A \bullet (t_h - t_c)}{Q_{sp}}$$

Where A (m2) is specimen area, th and tc (°C) are temperatures of specimen hot and cold sides, and Qsp (W) is the net flow of heat through the wall, equal to metering wall and flanking losses, Q(mw+fl), minus the metered input of heater and fans, Qaux.

Test No.	t_h(°C)	t_c(°C)	Δt(°C)	t_a(°C)	Q_{aux}(W)	Q_{sp}(W)	$Q_{(mw+fl)}$(W)	R(Km²/W)	R_{dwb}:R_{cmu}
105	14.2	-6.0	20.2	14.1	35.4	28.5	6.9	1.05	4.0 : 1
091	20.5	6.4	14.1	16.9	32.2	23.0	9.2	0.91	3.5 : 1
104	14.3	0.6	13.7	12.5	34.1	25.4	8.7	0.80	3.0 : 1
090	21.0	13.7	7.3	14.4	30.9	25.0	11.9	0.43	1.6 : 1

t_h: specimen surface temperature, hot side; **t_c**: specimen surface temperature, cold side; **Δt**: temperature differential (t_h- t_c); **t_a**: ambient lab temperature; **Q_{aux}**: total power input; **Q_{sp}**: heat flow through specimen; **$Q_{(mw+fl)}$**: heat flow through metering chamber wall and around panel; **R**: resistance to heat flow of the specimen; **R_{dwb}:R_{cmu}**: ratio of DWB R to published CMU R.

Table 2. DWB specimen wall results.

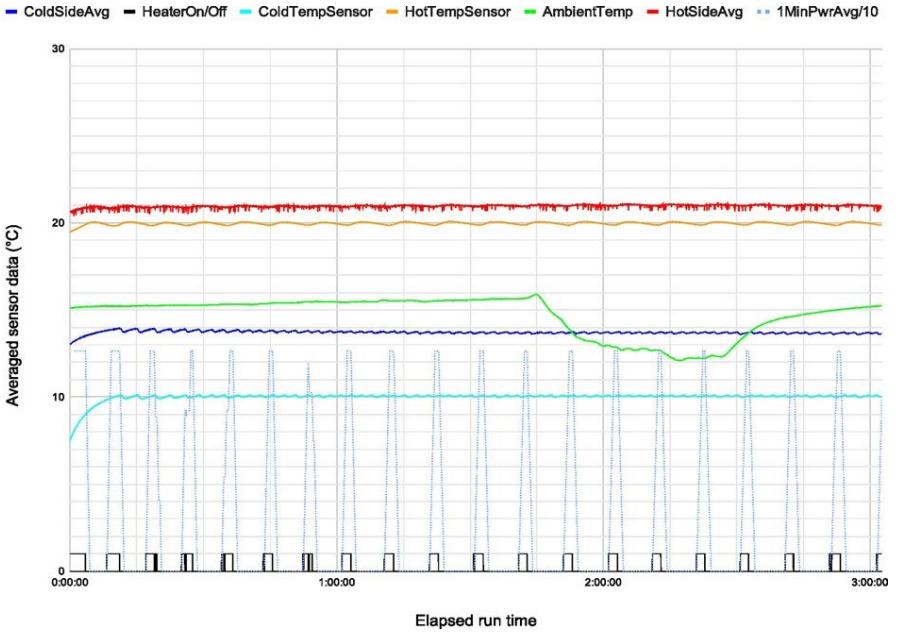

Figure 4. DWB wall specimen test no. 090. Steady-state observed after approximately 00:30:00 minutes.

Figure 4 illustrates temperature and power levels logged during a typical DWB specimen test run. Fluctuation of average temperatures measured across specimen hot and cold sides ("ColdSideAvg" and "HotSideAvg"), is ≤ 1°C, as required by ASTM C1363. Sensors used for thermostatic control of heating and cooling systems ("HotTempSensor" and "ColdTempSensor") also show recorded fluctuations ≤ 1°C, as required by ASTM C1363. Dip in ambient lab temperature starting ~ 1:45:00 due to exterior building doors being opened.

The value of R for the DWB specimen, calculated using power input Qaux and Equation 2, is regarded as relative, not absolute. As expected, heat flow through both the characterization panel and the DWB specimen increased as temperature differentials increased. As expected, heat flow through metering chamber wall to surrounding lab, Qmw, and flanking losses through the specimen frame, Qfl, both decreased as temperature differentials increased; test runs with higher differentials have less potential for error than test runs with lower differentials. Losses, Qmw+fl, are a higher percentage of total heat transfer than allowed by the ASTM standard, but significantly lower than losses reported for the apparatus designed by Seitz and MacDougall. Losses calculated during characterization using Equation 1 are relatively sensitive to an exact value for characterization panel R; since R is calculated from manufacturer's data rather than established empirically, this is a possible source of error. However, when R is calculated for the DWB specimen using Equation 2, the inverse is true, and the calculated value for R is relatively insensitive to the exact value of Qmw+fl.

Calculated R for the DWB specimen is up to four times higher than published values for nominal 152 mm thick, unreinforced single wythe wall assemblies of normal weight CMU with fully grouted cores (NCMA 2013). Because steel reinforcing rod has greater conductivity than concrete mortars and grouts, it is likely that R for a steel-reinforced CMU wall would be lower still, i.e., thermal performance of DWB specimen relative to reinforced CMU would be even greater. Construction and testing a reinforced and fully grouted CMU wall to directly compare thermal performance is an area for further research. The apparent correlation in Table 2 between higher R, higher temperature differentials, and lower cold side temperatures is also an area for future research.

CONCLUSIONS

The constructed hot box apparatus meets ASTM parameters for temperature control. Data acquisition and controls were found to be reliable. Flanking losses and metering wall losses were higher than prescribed, likely due in part to a metering chamber area proportionally greater relative to specimen area than would be the case for a larger apparatus. This could be mitigated by increased air-sealing of box sections and specimen contact with frame, as well as increased insulation of hot box chambers and specimen frame. Use of an LN2 cooling system permits rapid temperature changes and precise control, with low upfront costs, but operating costs are high (~$11 USD/ hour for test runs with ≥30° C differentials) and eventual replacement with mechanical refrigeration is planned. Nevertheless, the design represents a cost-effective alternative to commercial testing facilities, and is practical for use as a design tool in educational and R&D facilities.

Results of initial investigations favour the conclusion that DWB wall assemblies have higher resistance to thermal conductivity than CMU, even when using conventional reinforcement, mortar, and grout. This is further evidence for the potential of DWB as a high-performance, low-cost alternative

to CMU, and concomitant diversion of problematic C&D waste from landfills.
Hot box testing of DWB assemblies that utilize lower-conductivity reinforcement, mortar, and grout is an area for further research, with the goal of developing DWB wall assemblies that approach or equal thermal performance previously found for homogenous DWB specimens. Such assemblies could potentially meet energy code standards for non-residential construction, without requiring additional insulation. This would represent considerable reduction of labour and material costs. It is also appreciated that lower-conductivity reinforcement, mortar, and grouts may be higher performing with regard to embodied energy and carbon footprint.

PAPER #5.15

INDOOR ENVIRONMENTAL ANALYSIS OF A LEED GOLD-CERTIFIED OFFICE BUILDING IN ASHRAE CLIMATE ZONE 6

Antonio Martinez-Molina[a], Hazem Rashed-Ali[a], Jae Yong Suk[a]
[a]University of Texas at San Antonio UTSA, San Antonio, TX, USA

ABSTRACT

Building quality and performance can be assessed in terms of indoor air quality, thermal comfort, lighting quality, and acoustic comfort, collectively referred to as "Indoor Environmental Quality (IEQ)." User satisfaction in buildings has been clearly linked to productivity, lower absenteeism, and employee retention among other outcomes. Conducted as part of a larger Post-Occupancy Evaluation (POE) of a LEED Gold certified office building located in Wisconsin, USA (ASHRAE climate zone 6), this study takes a comprehensive approach to analyzing the IEQ of the building by employing a questionnaire conducted in parallel with measuring several indoor environmental parameters. The field measurements were used to explore, understand, and validate the outcomes of the survey.

The building is approximately 90,000 square feet including both private offices and open-plan spaces, plus other facilities. It is conditioned through a centralized HVAC system that separately supplies the three 2-storey wings and controls indoor temperature, relative humidity, and fresh air supply based on a pre-programmed algorithm. A total of 126 answers were collected out of 200 employees, representing a response rate of more than 60%. The questionnaires were collected and analyzed using the online survey tool: QualtricsXM.

The results show that office design layout and orientation play a key role in occupant satisfaction and productivity. Employee thermal comfort was strongly impacted by their location in the building. This was due to a mixture of design and operational issues, which also strongly impacted the building's energy use. As is expected in open plan design, issues with noise and privacy were also identified. The results however showed a high level of satisfaction with air quality, which was supported by the field measurements. The findings will inform architects, engineers, and researchers in their efforts to promote more efficient and healthy office spaces and to run POEs of existing office buildings.

Indoor Environmental Quality (IEQ); office building; Post-Occupational Evaluation (POE); LEED Gold; health.

INTRODUCTION

One of the key factors to improve occupants' health and productivity in the workplace is Indoor Environmental Quality (IEQ) (Fisk 2002; Hedge 2000; P. Wargocki 2000; Choi and Moon 2017; de Dear, Brager, and Berkeley 1998). In order to provide a healthy and comfortable indoor environment, buildings need to use energy for heating, cooling, ventilation, etc. Based on this thought, IEQ and energy efficiency go together while designing a sustainable and healthy building (Geng et al. 2019). Additionally, these two parameters are two key factors while certifying a building with the Leadership in Energy & Environmental Design (LEED). Generally, occupants are able to identify the air quality level through their sensory perception reflects, responding with yawns

and sneezes (Wolkoff et al. 2006). However, many of these parameters are difficult or nearly impossible to people to notice while working in their workplace. For example, Carbon Dioxide (CO2) is considered colorless and odorless, then occupants are unable to identify the concentration level, which can have a very strong impact on health. In fact, a high concentration of CO2 could derive in a sick building syndrome (SBS) (Gupta, Khare, and Goyal 2007).

A common best practice to understand the correlations between occupants' opinion and IEQ measurements is comparing the IEQ measurements with a Post-Occupational Evaluation (POE) (Loftness et al. 2009; Newsham et al. 2009; Veitch et al. 2007). In fact, Formaldehyde (HCHO), Total Volatile Organic Compounds (TVOC), CO2 and Particulates (PM2.5 and P10) are crucial IEQ parameters that are often considered in the field measurements of a POE.

It is critical to have good indicators in order to detect problems, monitor progress over time while trying to reach objectives (Cole 2005; Fisk, Black, and Brunner 2011). For instance, one of the most important parameters when identifying indoor air quality due to poor ventilation rate is CO2. This high concentration will generate dizziness, nausea, mental fatigue, throat irritation, headache and eye irritation, known as well as SBS symptoms (Thach et al. 2019). Moreover, most of the parameters responsible for this SBS symptoms are affected by outdoor air quality conditions, building ventilation system operations, and indoor activities (Cheng 2017). In 2017, a study showed that indoor air quality and thermal conditions generally affect performance, impacting negatively in the ability to concentrate and to think clearly (Pawel Wargocki and Wyon 2017).

This research presents an extensive IEQ monitoring campaign together with the results of exhaustive environmental questionnaire in LEED gold-certified office building in a cold climate. Authors believe that the collection of qualitative and quantitative data in addition to a thorough data analysis is the most accurate method to assess the thermal comfort and indoor environmental performance of a building. This study measured indoor concentrations of CO2, HCHO, TVOC, PM2.5 and PM10, air temperature and relative humidity, together with the subjective occupants' opinions of the indoor environment. The results and correlations of this paper can be used to determine a detailed characterization of the air pollutants present in office buildings and the impact of the office design on air quality and occupants' productivity.

1. DESCRIPTION OF CASE STUDY

The building analyzed is the Grande Cheese Corporate Home Office located in Fond du Lac, Wisconsin (USA), 5 miles South from the lake Winnebago and 40 miles West from lake Michigan (Figure 1). Fond du Lac is 760 feet above sea level and its climate according to the ASHRAE classification (Briggs, Lucas, and Taylor 2003), is zone 6. The building was completed in 2016, and its main use is administrative (office), although there are two cheese laboratories on the first floor. The structure consists of 83,402 ft2 air-conditioned space, of which 79,967 ft2 are offices, and 3,435 ft2 are lab spaces, all distributed in three wings with two floors each, surrounding a large internal courtyard. The office building also houses a fitness center, a cafeteria, two kitchens, a coffee room, a study room, a game room and a loading deck. Over 175 people occupy the building daily with a regular office schedule from 9:00am to 5:00pm Monday through Friday, although a few of the occupants work different hours since the building is accessible 24/7. Additionally, the building is LEED gold-certified by the United Stated Green Building Council (USGBC). This

certification proves the building performance in terms of energy efficiency, water usage, air quality, and choice of building materials as well as environmental factors such as access to public transportation and responsible land use.
The HVAC system is divided in three sections that each one of them supplies fresh air, heating and cooling to each building wing. However, the two cheese laboratories, with dedicated 100% outside air HVAC, are independent of the general HVAC system. The office spaces have two different typologies, open spaces with individual cubicles, and private offices and small conference/meeting rooms. These diverse office designs generate very different occupants' satisfaction.

Figure 1. Grande Cheese LEED gold certified building. Exterior (left) and courtyard (right) views.

2. METHODOLOGY

This study was conducted in an office building equipped with a mechanical ventilation system, including air and heating cooling, and air supply devices, for maintaining comfortable room temperatures and good indoor air quality. A very detailed data collection campaign was performed combining qualitative (occupants' satisfaction) and quantitative (environmental monitoring) data. This campaign took place June through August 2019.

2.1.Questionnaire

In order to understand what type of opinion occupants currently have of the indoor environment, the research team used an analytical qualitative method with online questionnaires as main tool. The questionnaire included multiple-choice questions (using Likert-type scales) and open-ended fields, and was divided into the following sections: Individual data; personal workspace; office layout; thermal comfort; air quality; acoustic quality; building features; and general comments.
An anonymous link to access the online questionnaire prepared on the Qualtrics ("Qualtrics XM" 2019) platform was sent to occupants of all departments and was kept open for three months (from June 2019 to August 2019). The link was distributed to the participants via email and reminders were sent periodically by using the same strategy. The questionnaire was designed with the goal of extracting honest and reliable responses with the following considerations in mind: brevity and simplicity. Indeed, it was unlikely that occupants would have filled out the questionnaire if it was too difficult to understand, and responses would not have reflected the real experience.

2.2. Indoor environmantal monitoring

Indoor and outdoor temperature and relative humidity levels of the office building were monitored for the duration of the of 3 months and data gathered at one-hour intervals. The equipment utilized for the internal monitoring was carried out with the use of a pre-installed network of data loggers evenly distributed throughout the building. To evaluate the indoor environmental quality, one-time noise, CO2, HCHO, TVOC, PM2.5 and PM10 measurements were taken during a regular building operation day, in every room.

3. OUTCOMES

This part presents the results of the quantitative objective monitoring through data logger and the results of the qualitative investigation through questionnaires, in order to assess occupants' satisfaction with the indoor environment. These outcomes are divided in three sections: thermal satisfaction; acoustic satisfaction; and air quality satisfaction. As shown in Table 1, the response sample analyzed in this study was evenly distributed along the entire building, therefore, this data can be considered reliable and representative of the case study. The 1st floor on the North wing does not house offices (only common areas), therefore, there were not responses collected in that area.

3.1. Thermal satisfaction

Table 1 summarizes the 3-months indoor average temperature values monitored, showing mainly that there is a significant difference between floors. While 1st floor temperatures range between mean values of 69°F or 70°F, 2nd floor has higher values around 73°F. Based on the sustainable building design and usage, and the occupancy pattern, this 3°F - 4°F difference between floors is very substantial and worth to investigate.

Despite the temperature difference shown in Table 1, Figure 2 depicts that most of occupants feel thermally comfortable in the building (67%), and only 5% of them reported being hot. However, it is very significant that 28% of workers answered to the questionnaire reporting feeling cold (28%). This 28% is too high and does not fit in the parameters that are acceptable to consider the building thermally comfortable (Paliaga et al. 2013). Looking at floor level, there is an insignificant difference in answers between the 1st and 2nd floor, therefore, a more detailed analysis was required (Figure 3).

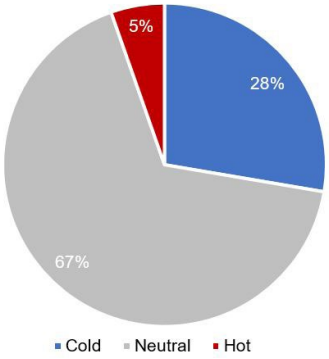

Figure 2. Total workers' subjective thermal comfort opinion.

		Questionnaire Responses	Indoor Average Temperature
1st Floor	West Wing	23%	70.3
	South Wing	25%	68.6
2nd Floor	West Wing	21%	73.2
	South Wing	23%	73.5
	North Wing	8%	72.4

Table 1. Spatial distribution of questionnaire responses, plus indoor temperature values.

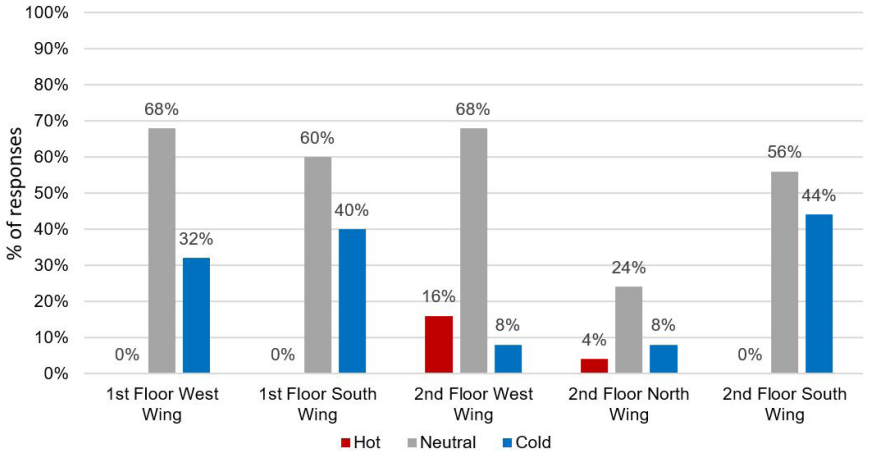

Figure 3. Workers' subjective thermal comfort opinion by building wings.

A result breakdown among different wings and floors is depicted in Figure 3. While there was no disparity between 1st and 2nd floors, building wings get very diverse answers. While West and North wings are consistent with 70% neutral, 20% cold and 10% hot answers, the South wing occupants reported being only around 60% neutral and 40% cold. This data locates the occupants reporting being cold and narrows it to both floors of the South wing. The questionnaire results also revealed that office design has a significant impact on thermal satisfaction. Occupants in closed offices feel colder (34%) than workers using an open space office (cubicles) 10%. Combining all the answers gathered, building occupants have a general opinion of being cold while being in their workplace.

3.2. Acoustic Satisfaction

As mentioned above, offices design heavily impacts on the overall occupants' experience. The acoustic performance of the building is not an exception. Figure 4 presents the results of workers satisfaction to the buildings' noise level, sound privacy and noise satisfaction based on office design. The 78% of occupants

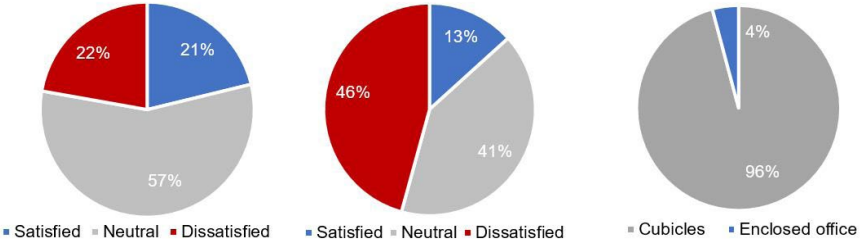

Figure 4. Total occupants' noise level (left), sound privacy satisfaction (center) levels, and location of dissatisfied occupants (right).

described their noise experience as neutral or satisfied, against 22% of the answers were negative. Regarding sound privacy, dissatisfied answers are higher reporting a 46% of negative opinions. This undesirable number of discontented occupants (46%), were located mainly in cubicles in the open office spaces. Therefore, this negative feedback is due to a design solution since, in general, open office spaces have less privacy.

3.3. Air quality monitoring

It is very difficult that occupants notice pollutants, that is the reason for mostly relying on the monitoring results instead of occupants' opinion. However, an air quality satisfaction question was included in the general questionnaire with very positive results. Figure 5 depicts the occupants' great opinion regarding indoor air quality with only 1% of the surveyed workers unsatisfied.

As a part of the indoor monitoring campaign, Formaldehyde (HCHO), Total Volatile Organic Compounds (TVOC), Carbon Dioxide (CO2) and Particulates (PM2.5 and P10) were measured throughout the entire building. Particulates are responsible for sore throat, eye irritation, and nervousness (PM10), and there is a strong correlation between PM2.5 and perceived air quality by occupants.

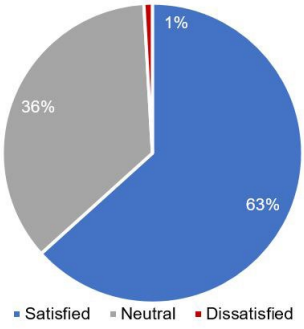

Figure 5. Total workers' air quality opinions.

The way of addressing and reducing these particulates levels is cleaning the duct system, filter replacement and cleaning carpets. Figure 6 shows the levels of PM2.5 and PM10 all rooms analyzed in the building. It is very clear that indoor levels are very low and far away from the recommended limits of 35PPM for PM2.5 and 150PPM for PM10 according to the American Society of Heating, Refrigerating and Air Conditioning Engineers ASHRAE and EPA. In fact, the outdoor readings are the higher registered with 14.1PPM (PM2.5) and 20.8PPM (PM10). Figure 7 shows other critical indoor environmental aspects that were measured such as Total Volatile Organic Compounds (TVOC), Formaldehyde (HCHO), and Carbon Dioxide (CO2). Regarding the CO2 readings registered in the building, they are very consistent ranging between 100PPM and 172PPM with the only exception of the areas where more people are concentrated such as open office spaces (294) and conference rooms (201). Moreover, in the loading deck CO2 values were 647PPM, a total of a 100% more than the second highest recorded value. This high value could be attributed to trucks that regularly park in the loading deck to deliver supplies for the labs. All these CO2 figures are below the maximum recommended value of 800PPM (Park et al. 2019). Concerning TVOCs, concentration values are below the recommended parameters except, once again, open offices, conference rooms and kitchen. However, the readings in the laboratories, cafeteria and loading deck are close to this limit of 1PPM. In particular to HCHO, all the rooms in the building have concentrations below the recommended limit of 0.40PPM, except the laboratories. It is worth mentioning that these laboratories have dedicated 100% outside air HVAC.

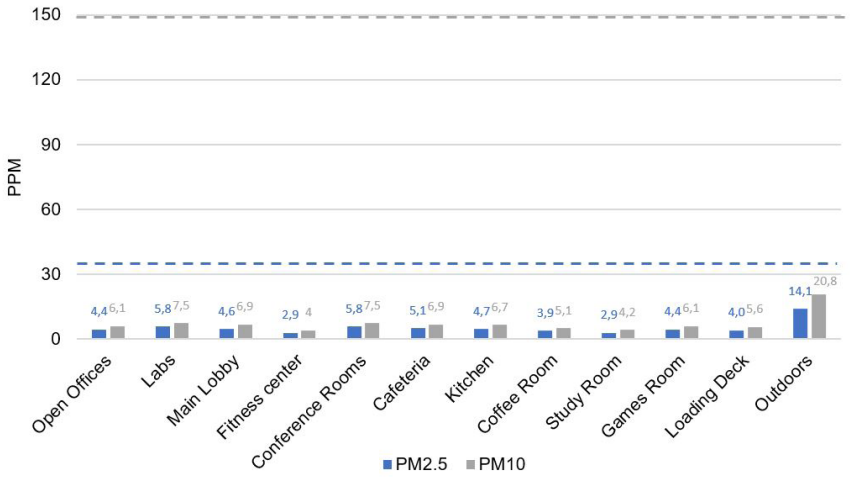

Figure 6. 2.5 and 10 Particle Matter field measurements by location.

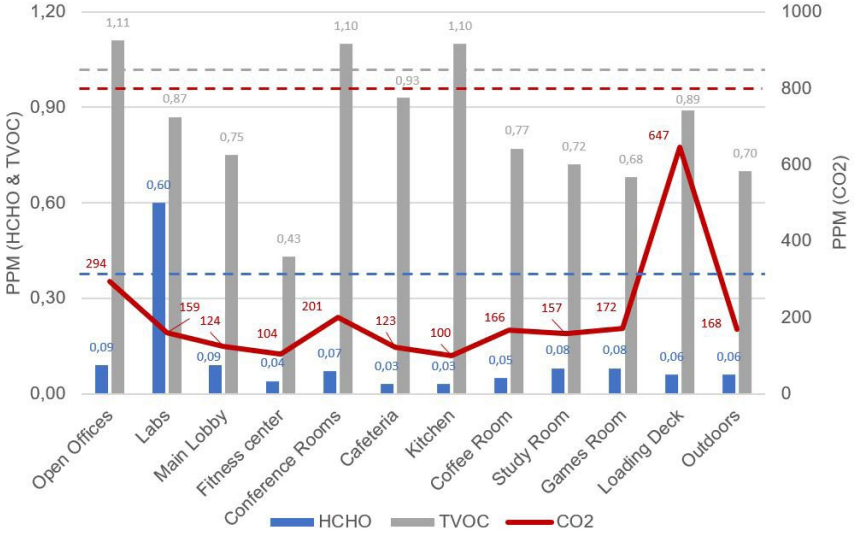

Figure 7. CO2, HCHO and TVOC field measurements and recommended limits, by location.

CONCLUSION

From user satisfaction surveys in this LEED gold-certified office building in ASHRAE climate Zone 6, 64% of occupants overall responded "satisfied", 27% answered "neutral" and 9% of occupants reported "dissatisfied" with their indoor environmental conditions.

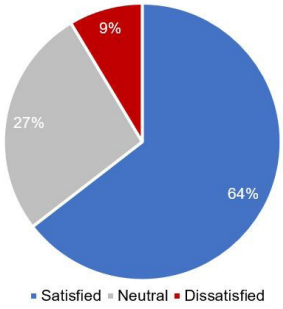

Figure 8. Total workers' overall building satisfaction based on indoor environmental quality.

While 1st floor temperatures range between mean values of 69°F or 70°F because of the impact of the HVAC system, 2nd floor has higher values around 73°F, probably due to the solar radiation. With these temperatures, 28% of occupants felt cold or very cold which is a percentage too large for high performance building. Most of these unsatisfied occupants were located in the South wing, particularly on the first floor and seating in open office spaces. Occupants also reported being cold during both seasons, winter and summer. Due to the building design and occupancy pattern, this reported discomfort could be easily addressed with location specific HVAC operation. Large office buildings are impacted by the outdoor environment in different ways and building locations, therefore, require a HVAC broken down approach for each particular area.

Furthermore, open space offices are proven to promote occupants' interaction and accountability, however, sound privacy and noise are the main two negative aspects of this design solution. Occupants seating in open office spaces reported a 46% of dissatisfaction of sound privacy. This is a design approach that has these negative consequences and there are very limited applicable solutions that can be implemented such as higher partitions, etc.

Given the measured air quality concentrations, occupant satisfaction with overall air quality is very positive. Most rooms do not exceed the recommended thresholds, only particular locations with high occupancy levels like open office spaces and conference rooms. The loading deck is a very different space form the rest of the building where truck engines are constantly running and the CO2 readings are the highest, but not exceeding the permitted parameters. When a mixed used space is located inside a building with occupants and vehicles together, a very strict ventilation strategy must be in place to reduce exhaust air and other pollutants. One of the most interesting aspects about this building is that the cheese laboratories, have dedicated 100% outside air HVAC, and are independent of the general HVAC system. These laboratories generate high quantities of air pollutants (highest HCHO level in the building beyond the recommended values) and need a very strict ventilation strategy in order to preserve optimal conditions for their operation.

As a result, it can be concluded that occupant satisfaction can help inform design decisions. Among the technical attributes of building systems, the factors mentioned above are critical for user satisfaction and health and can support workspace design. Moreover, this research demonstrates that the use of occupant satisfaction surveys could redefine user comfort thresholds.

ACKNOWLEDGEMENTS

Funding for this project was generously provided by Overland Partners, who also provided the design information for the project. The research team would also like to thank Grande Cheese Company for providing the building's operational information and allowing the team access to the building.

PAPER #5.16

ANALYSIS OF ENERGY PERFORMANCE IN A RESIDENTIAL BLOCK IN THE ENSANCHE OF VALENCIA AND PROPOSALS FOR IMPROVEMENT

Vicente Blanca-Giménez[a], Natalia Cardona Guerra[a]
[a]Universitat Politècnica de València, Valencia, Spain

ABSTRACT

The installations and construction systems in a typical residential block in the *Ensanche de Valencia* quarter have been analysed, and the parameters that allow economic costs to be optimised have been quantified, and can be extrapolated to other similar blocks in the neighbourhood, giving us a global vision. The construction dates from 1910, affecting a total of 92 homes. We start by taking construction and energy data. Then we calculate the urban compactness and complexity and take the reference grid. Houses and premises have been asked for receipts for energy consumption. A survey has also been developed to assess the acceptability of energy saving measures. Final y, we implemented the thermography technique.
After diagnosing the real situation, we developed the analysis for the viability of building's services improvements. To conclude, the results are presented according to the convenience or not to install active systems, as well as a rethinking of the enclosures in order to minimize energy consumption.

KEYWORDS

Rehabilitation; energy consumption; building envelope; efficiency.

INTRODUCTION

Valencia is a city located in the East Coast of Spain. (Longitude 0º22'28"W Latitude 39º28'36"N). Its maximum altitude is 24 meters above the sea level. The average annual temperature in Valencia is 17.4°C. The approximate rainfall is 445 mm.
The intervention takes place in the Ruzafa district, located in the southeast of the city, which nowadays is part of Valencia historical centre, and is of outmost sociocultural importance. The permanent relationship that already existed between Ruzafa and Valencia when the former did not belong to the city, increased with its annexation, and was later reinforced due to the project for urban centre widening (in Spanish, *"Ensanche"*). Ruzafa enjoyed the title of municipality between 1863 and 1877, when it was finally annexed to the city of Valencia, and started being a residential neighbourhood with major commercial activity [1]. Figure 1 shows the urban planning scheme for the *Ensanche*, where the existing town conditions the alignments and so the pre-existences have major importance. The new building regulations coexist with a public space typical of the old town, totally different from the orthogonal plot that characterised the first *Ensanche* of Valencia, resulting in a spatial configuration with its own personality and particular conditions which are of great interest. (fig.1).
The urban organisation of this nucleus laid out around the church of San Valero and the axis formed by Ruzafa Street, which links the neighbourhood to the city centre and the unique irregular streets. Concerning the building, it is characterised by an architecture built for the middle class and bourgeoisie, based on dwellings between party walls, facing the street and the inner courtyard of the block, which has modified its regulations over time and varied its formal language

through the use of new materials. The urban regulations of the "Ensanche" provided for the construction of buildings with a maximum of three floors, but successive regulations have progressively increased this height to 8 floors in some cases [2].

Figure 1. Russafa's district. Source: (C. Jiménez 2014)

Figure 2. Building at the crossroads of Carlos Cervera and Cura Femenia streets

The model chosen is an extension block made up of 8 residential and commercial buildings with a total of 92 dwellings arranged over a ground floor plus three floors, bounded by the streets Cura Femenia, Carlos Cervera, Dels Tomasos and Cádiz (Figs.2 and 3). Energy performance data of the buildings have been taken to implement, improvement measures, aimed at minimising overall consumption [3]. The final aim is to ensure that the comfort of the occupants is achieved through the rational use of energy in the buildings. [4]

An assessment has been carried out using the CE3X tool to obtain the qualification of energy efficiency in the existing residential buildings. Energy bills have also been collected to provide evidence of their actual expenditure. Subsequently, a survey has been carried out with two different groups of questions: a first one to indicate the real environmental performance of the house, and a second one which reveals the degree of satisfaction of the user. Finally, the construction performance of the building was studied and the thermal losses along the building envelope were located using a thermographic camera.

Figure 3. Selected buildings. Source: Sede Catastro Valencia.

1. OBJECTIVES

- To evaluate the real performance of the building, an extension block in the city of Valencia that can be extrapolated as a repetitive typology to other buildings in the neighbourhood [5]
- To compare the current performance with what could be reached if a series of technological improvements were implemented to minimise consumption
- To adopt measures to improve the energy efficiency of housing
- To provide a formal opinion on the construction system used in buildings which, as a result of their age, are significantly different from current ones, mainly in the treatment of the building envelope. We emphasise on the use of passive systems (walls, windows, blinds, carpets, curtains, carpets, etc.) to act as corrective screens and reducing dependence on artificial systems.

2. METHODOLOGY

In order to achieve the proposed objectives, a methodology has been developed to obtain the necessary information and draw conclusions for possible intervention, according to the following steps: (1) Carrying out a graphic analysis of the buildings and the extensions that have been made from their original state; (2) characterisation of the building envelope; (3) carrying out surveys of the homes' residents who make up the extension block, so to get information on the conditioning systems, degree of well-being of the homes and willingness to incorporate active and passive measures in the block; (4) evaluation of real energy consumption through energy bills for both electricity and gas (owners were asked to provide the "CUPS" (Universal Supply Point Code) on their bills), which allow (5) the results of the simulator to be compared with reality; and (6) results are justified by means of thermography simulation of every internal and external part of the building envelope that form the block.

All data collected were processed and analysed using the programmes recognised by the Ministry of Industry, Energy and Tourism (MITECO): CE3X version2.1., CE3 version 2375.1015, HULC version 20151113, and CERMA version 4 to characterize the houses from the energy perspective, as well as to check whether there have been alterations in the results.

3. DATA ANALYSIS AND RESULTS PRESENTATION

Climate data:

The climate data for the city of Valencia (table 1) and the construction of the buildings under analysis have been taken into account.

Constructive materialization:

The buildings were constructed using the characteristic construction techniques of this period, thus:

- The main façades are solved with solid brick load-bearing walls of one and a

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
T avg (ºC)	11.2	11.1	13.4	15.3	18.2	21.8	24.6	24.9	22.8	18.9	14.5	11.9
T min (ºC)	6.8	7.3	8.6	10.6	13.8	17.5	20.4	20.9	18.4	14.3	10	7.5
T max (ºC)	15.7	15	18.3	20	22.7	26.1	28.8	29	27.3	23.5	19	16.3

Table 1. Climate data for the city of Valencia

half or two feet thick and joined with lime and mortar cement (thermal transmittance value U=1.22 W/m2 ºK.)

- The rear façades have half a foot of solid brick wall closing the interior doorway (U= 2.13 W/m2 ºK.)
- The dividing walls are the building's own wall separating the boundaries, made up of piled up walls of solid brick, half a foot thick, and taken with lime mortar (U= 2.42 W/m2 ºK.)
- The sloping roof is formed with purlins interposed to bard bricks. This layer is the base on which 3 or 4 cm of lime mortar is poured directly onto the Arabic tile (U= 3.45 W/m2 ºK.)
- The "Catalan" style flat roof is made up of three layers of ceramic tiles plus the floor, supported by purlins, which are in turn supported by the roof structure (U= 3.33 W/m2 ºK.)
- The floor that divides the commercial premises is made of unidirectional wooden beams and covered with a two-threaded revolving floor of ceramic pieces. The hydraulic floor is supported by a 2 or 3 cm lime mortar filling. (U= 2.42 W/m2 ºK.) [6]

Surveys of residents:

From surveys conducted to residents (Table 8), which were answered by 32% of them, it is possible to know the current status of the building (Tables 1 and 2), as well as inferring a well-being indicator (Table 3). It can also be gathered from the surveys the degree of a person's liking on the changes required for the inclusion of new measures to improve the current situation. All the information collected during the study has provided an understanding of what their needs are, and the relevance that each resident gives to them (Table 4). Finally, it is appreciated that any measure that can technically solve a deficiency, may not necessarily imply an improvement in the well-being of the residents (table 5). The ultimate aim of the proposed questionnaire is to evaluate the degree of acceptance of common energy saving measures by the residents of a block of homes. The form used for the survey is shown in table 7.

Tabla 7. Survey Questionaire Model used

Energy simulator:

The evaluation of the energy consumption demand has been carried out using, as already indicated, the tools endorsed by the Spanish Ministry of Energy, which enable obtaining the energy efficiency rating in existing residential buildings, and easing a detailed study to improve the resulting rate. In this study the simulation results were compared with the real energy consumption data, by means of the electricity and gas bills of the visited homes. The obtained model indicates that the maximum demand of energy occurs during winter time, and not that much in summer (Fig.4). In terms of the buildings' envelope, results indicate that the most generalized losses arise from the rear facades, where the is almost no isolation at all. Another construction element where significant losses are produced is through the roof of the buildings.

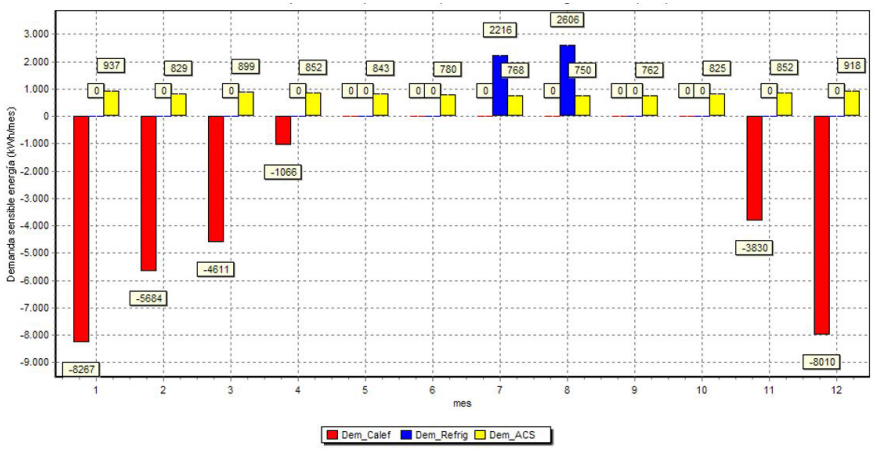

Figure 4. Energy consumption demand of a modelized building (kWh/month)

Measurements:

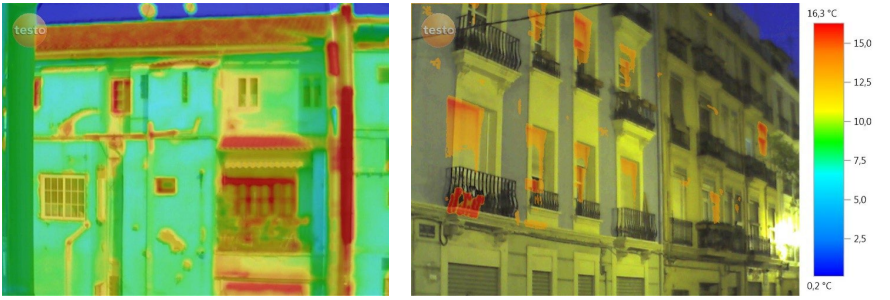

Figure 5. Thermografy measurements taken for inner and outer facades (note the effect of shadowing over facades thermal performace) Source: (Vicente Blanca 2012).

The thermographic measurements performed over the facades of the buildings under study confirm the result of the simulation modelling. The most significant losses occur through the rear facades and the wooden enclosures (Fig. 5).

4. DISCUSSION

Concerning the proposal of a global improvement of the building's thermal envelope, , it is concluded that about 10 cm of insulation would be needed, to reduce CO2 emissions, until the letter initially obtained in the energy rating, which was an E, is modified. This thickness would be required to be enlarged to 10cm for the facades and roofs and, in addition, to install low emission glass windows, to reach a qualification of D, one level above the current one [7].

A possible way to alleviate the economic effort that the building envelope global improvement would mean, considering the very long amortization periods estimated, is to make specific improvements in particular points, like only isolating the clearly deficient facades,which are those facing the inner courtyard, or to restore the windows and their shields [8].

Obviously CO2 emissions are reduced to a minor amount, but if it is related to the investment to be made in each case, from the perspective of the optimum cost of the action, it would be more feasible to consider this type of intervention, taking into account the specific climatic conditions of Valencia.

In relation to the possible position of the thermal insulation in the facades studied, it could be concluded that in the main facade which is very thick and has a high thermal inertia, the placement of the insulation is not excessively relevant. Furthermore, in the walls of the rear facades, which are very thin and have a high level of inertia, the differences between the two situations are more pronounced, although not substantial. In these cases, placing the insulation on the inside of the façade has a significantly better performance in winter conditions, but worse than in summer. On the outside, the behaviour is the opposite, that is, it works better in summer. In any case, considering that many of the main façades of the buildings in the neighbourhood are protected, if the installation of the insulation on them were planned, it would only be possible to intervene on the inside.

With regard to the façade openings, it has been observed that the original woodwork was made of wood, an important aspect given the low conductivity of said material. Nevertheless, it has been found that many of

the original woodwork has been replaced and, in the case of the solar protection, it has been altered or removed. The aim is to recover and improve the thermal behaviour of the original damaged wooden windows, including their protection (blinds, shutters, gazebos, etc.), which in many cases has been removed. In this sense, it is understood that the most interesting option would be to repair the carpentry by placing flashing to improve its behaviour with regard to air permeability and the arrangement of the corresponding glazing beads to be able to place double glazing with a chamber, so that, if the replacement of original glass is considered, normally of very little thickness, ranging between 3 and 6 mm. by 4/12/4 [9][10]

If intervention on the enclosure and on the installations is considered, it is concluded that CO2 emissions are reduced, but not enough to reach a letter C in the energy rating [11]. Only the installation of a biomass boiler could achieve a letter B. As these are through houses with two opposite facades, it favours good ventilation, an important aspect especially in summer [12]. Another system typical of this type of building for natural ventilation is the staircase itself. In order for it to work properly, in addition to the usual openings to the interior courtyards, it is vital that it also has them at the top and bottom of the stairwell, that is, in the hallway and the roof [13]. It has been observed that, in many cases, the original doors of the building have been replaced, which had practicable elements in the upper part to favour the entry of air and the consequent ventilation through the staircase. The recovery of these simple natural ventilation systems has been considered, given that the cost-benefit ratio in summer is very beneficial, but incorporating control systems over the openings so that they can remain closed in winter [14][15][16].

CONCLUSIONS

Given the difficulty created in the collection of energy data, as a result of the distrust created by the occupants of the homes and the lack of information, it has been very positive to provide the homes with intelligent meters.

There have been no relevant changes in the results obtained with the use of the software backed by the Ministry of Industry, Energy and Tourism, when characterising the energy of the homes.

In a warm climate, such as the city of Valencia, the years needed to recover the investment, if it is considered the rehabilitation of the entire enclosure, are more than 10 years. This means that energy service companies are not interested in managing the renovation of buildings with these climatic characteristics. In this sense, the most relevant result is the improvement of the thermal comfort and the quality of life of the users, more so if we consider that a high percentage of homes do not have heating systems. Another problem detected is the high number of uninhabited dwellings in the buildings of the neighbourhood. This differentiates the theoretical results obtained by means of the computer tool from the real global consumption data for each building. This situation is aggravated by the fact that most occupied dwellings are occupied by users over 65 years of age and, in many cases, they live alone. All these problems together mean that the owners are not interested in investing in their houses' rehabilitation.

The very uniformity of the cornice heights in the buildings, that make up the neighbourhood, avoids the shadows cast by facilitating the incorporation and use of renewable energies through thermal and photovoltaic solar panels, notably improving the building's energy management [17].

The division of the urban development, the similarity in construction, the occupation of the houses and the socio-economic study carried out, allows us to extrapolate the values obtained, as well as the indicators, to other blocks in the same neighbourhood.

PAPER #5.17

COMPARATIVE STUDY OF SUSTAINABLE THERMAL INSULATING MATERIALS IN ARCHITECTURE

Jose Vercher[a], Joaquin Segura[a], Enrique Gil[b], Angeles Mas[a], Carlos Lerma[a], Carlos Silvestre[a]
[a] Deparment of Architectural Constructions, Universitat Politècnica de València, Spain
[b] Deparment of Continuum Mechanics and Theory of Structures, Universitat Politècnica de València, Spain

ABSTRACT

The study aims to know the alternatives to thermal insulation currently used in the type of double-sheet enclosure, with or without an air chamber, and thermal insulation inside. Objective data is provided to justify the value of new eco-friendly thermal insulating materials that allow a more respectful architecture with the environment.
Ecological awareness today reaches any discipline. Architecture does not escape this concern and, therefore, new, greener materials are introduced. On the other hand, the new regulations advocate for more efficient, ecological and sustainable construction.
In this sense, the new materials come from natural sources or from recycled products, which, through simple transformation processes, achieve a new product that complies with current regulations, as well as new social and architectural requirements.
To know the characteristics of these sustainable thermal insulating materials, a comparative study of different products is carried out, contrasting their characteristics and properties. The formats that best fit the double-sheet enclosure solution are the blanket, board and bulk. The selected thermal insulators are natural cork, cotton, hemp, cellulose, sheep wool and wood fiber.
In order to determine their behavior, several technical features are studied. In addition, some environmental properties are evaluated to complete the comparison. Various studied aspects are the origin of the raw material, the consumption of energy and the level of emissions generated by the manufacture.
All values and data obtained show the thermal and ecological insulating value of the studied sustainable materials against those currently used in the construction of enclosure systems.

KEYWORDS

Thermal insulation; sustainable; recyclable; comparative study; ecological.

INTRODUCTION

Over time, humans have taken into consideration their environment regarding architectural construction in terms of the collection of materials, the climatic conditions and the adaptation to the surroundings. However, this adaptation has been abandoned mainly due to the technological developments that have been incorporated during the industrialization. From that moment on, we have arrived to a point in which the construction of buildings consumes 40% of the materials, generates 40% of wastes and consumes 40% of the primary energy in the European Union (Baño & Vigil-Escalera 2005). A great amount of this consumption takes place due to the building activity in cities. Technology has improved living conditions and has provided more suitable conditions to increase the amount of population. Nonetheless, it has now a responsible role in the development of sustainable ways to preserve and keep improving social welfare. In this sense, many courses are being taken

at this precise moment. In a long term research, bioinspired materials and artificial reproduction of existing substances are two of the most growing research fields. Regarding building conditions, thanks to the growth of a more ecological consciousness, a change towards sustainable construction is slowly taking place. This transition is necessary considering that if we maintain the current consumption rate, the stocks of the different fossil fuels will disappear: between 35 and 45 years for petrol, between 60 and 70 for natural gas and between 200 and 230 for carbon (BP 2013). Hence, sustainable construction, which is based on respecting and adapting to the environment, saving resources and energy, and considering the users, becomes a wide field of research to reduce our consumption rate. Embracing both sustainable construction and technological development, this paper outlines another approach towards what a future based on technology could be: the use of more natural, sustainable and environmentally friendly materials in the building industry.

> The use of fossil fuels for heating, lighting and ventilation of buildings is responsible for the 50% of the global heating, being transport another of its main causes (25%) (Edwards 2005, 4).

Thus, amongst the variety of natural and environmentally friendly materials, this work aims to provide further information on those which are thermal insulators, sustainable, available in the market and feasible to implement in the most common brick wall constructive technics in Spain: the double layer façade with and without air chamber. Consequently, this study is framed on the second condition of the sustainable construction (saving resources and energy) since it will delve into the study of thermal insulator materials that are suitable, have low environmental impact and have properties with high influence on the energetic behaviour of buildings. In order to consider these materials as potential substitutes of the traditional thermal insulators they will need prove of being not only more sustainable but also provided with at least as good properties as the traditional materials.

1. MATERIALS AND METHODS

The aim of this paper is to present the research made on several sustainable thermal insulators in order to review their potential as substitutes of the traditional materials. To do so, a precise methodology has been applied along the investigation. It consists of a comparison between the sustainable materials and with the traditional ones both in technical aspects and in environmental features. The first consideration emphasizes their suitability to perform as thermal insulators, since they should behave as well as de usual thermal insulators, while the second allows determining the level of sustainability and environmental impact amongst them. To accomplish this comparison, their technical features and environmental characteristics have been translated into numeric parameters. The studied technical aspects have been the following: *Thermal conductivity, λ [W/mK]:* it is an indicator of the heating transmission capacity and represents the ease of the material to conduct it. The smaller the value of λ, the better the thermal insulator. *Thickness*, *e [m]*: to achieve an equitable comparison, a certain thermal resistance is fixed, R = 1m^{2}K/W. Thus, for the same value of thermal resistance, the value of the thickness of each material is obtained

$$e = R \cdot \lambda \qquad [\,1\,]$$

Where: R = thermal resistance [m^{2}K/W]
λ = thermal conductivity [W/mK]

All the studied materials present a thickness of 40 or 50 mm as the value that would correspond with the closest commercial value available.
Hygroscopicity [%]: the capacity to absorb or spread the humidity in the air. It promotes the equilibrium of internal humidity. The higher the percentage, the better hydrophilic behaviour.
Water steam diffusion, Sd [m]: the capacity of a material to allow water steam to move through it. Materials with a good water steam diffusion are prone to expel out the steam.

$$Sd = \mu \cdot e \qquad [2]$$

Where: μ = resistance to steam diffusion
e = thickness of the material [m]
Being Sd: <4: optimal
4-7: satisfactory
7-15: bad
15-25: very bad
>25: impermeable barrier to steam

Thermal diffusivity, α [m^2/s]: it is the expression of the capacity of a particular material to transmit a variation of temperature in a specific time. The lower the value, the longer it will take the material to transmit a variation of temperature from the exterior to the interior.

$$\alpha = \frac{\lambda}{\rho \cdot C\rho} \qquad [3]$$

Where: λ = thermal conductivity [W/mK]
ρ = density [kg/m^3]
Cρ = specific heat [J/kgK]

Fungi and insect resistance: all the studied materials present this feature.
Fire resistance: it is expressed according to the Euroclasses:

A Non-combustible, no contribution to fire
B Combustible, very limited contribution to fire
C Combustible, limited contribution to fire
D Combustible, middle contribution to fire
E Combustible, high contribution to fire
F Unclassified, no specific fire behaviour

Price [€/m^2]: the indicated price belongs to the material according to the appropriate commercial thickness to ensure R = 1m^2K/W.

The environmental characteristics of each material can also be translated into tangible numbers to facilitate the comparison between their values. In that sense, the following magnitudes are the ones that have been evaluated:
Energy [MJ/kg]: total energy consumed along its life cycle.
Emissions [kgCO^2/kg]: CO_2 emissions during the whole life cycle of each material.
Biodegradability: is the ability of organic substances and materials to be broken down into simpler substances through the action of enzymes from microorganisms. If this process is complete, the initial organic substances are entirely converted into simple inorganic molecules such as water, carbon dioxide and methane (Ecozema 2020).
Recyclability: is a characteristic of materials that maintains useful physical or chemical properties after serving their original purpose and therefore allows them to be reused or remanufactured into additional products through a recognized process. All the studied materials are recyclable but the bulk format is itself harder to recycle.
After determining all the numeric parameters considered in the study, it is necessary to narrow the scope of the research and adequate it to a feasible analysis which could provide conclusions. To do so, four conditions have been applied to preselect the materials (Fig. 1): the material must be sustainable, thermal insulator, the material must be available in the market and it must be feasible to implement in the most common construction systems.
The double layer façade with and without air chamber are the most common brick wall constructive technics in Spain. This condition is applied to reduce the variety of formats of the materials to either board or blanket and bulk. The formers are meant to be implemented through fixation while the latter is used as insufflated insulator. The materials that fulfil all these requirements are potential substitutes of the traditional thermal insulators used in the building industry. The

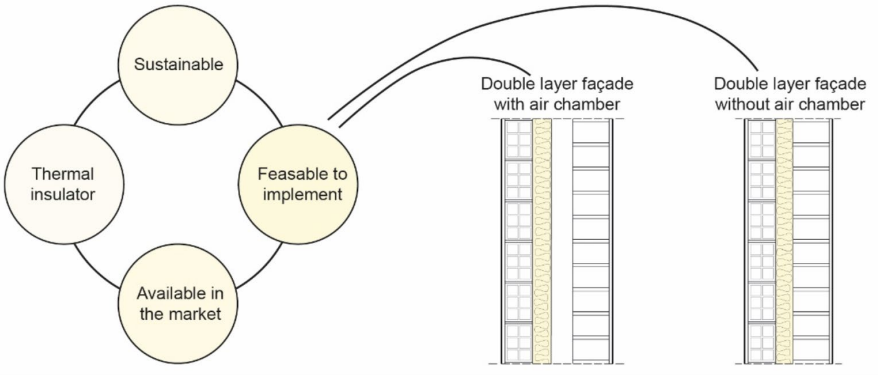

Figure 1. Conditions to select a material.

resulting ones are cork, hemp, wood fibre, cellulose, sheep wool, cotton and mineral wool. They are commented in the paper hereunder. Once the materials have been specified, the condition of availability in the market will determine which formats are studied for each material. This specification on the configuration of each of them is worth to be highlighted because it is not equivalent to all the materials. There are some that can be transformed to be implemented with different technics while others are limited to a single application (Table 1).

Materials	Format		
	Board	Blanket	In bulk
Cork	x		x
Hemp		x	
Wood fibre	x	x	x
Cellulose			x
Sheep wool	x	x	x
Cotton	x	x	x
Mineral wool		x	x
Glass wool		x	
Extruded polystyrene	x		

Table 1. Formats available in the market.

1.1. Cork

Natural cork consists of the rind of the cork oak, which is made up of death cells that are filled with a gas similar to air. This gas constitutes the 90% in volume of the cells and is responsible for the low weight and compressibility of the cork. The extraction of the material from the tree does not damage it, since this process takes place mainly in July when it offers less resistance to be detached, and it does not require cutting down the tree, providing a renewable and durable process (Barnacork 2020).
Cork presents a great mechanical strength due to its ordered cell structure that does not allow gaps between them. Thanks to its resistance against atmospheric changes and the impossibility to rot, cork does not suffer dimensional variations along its useful life (Barnacork 2012). The product is 100% natural, since it only needs water steam and an increase of pressure. The glue used to ensemble agglomerate cork should be water based and totally biodegradable (ICSuro 2020).

Figure 2. Cork: in bulk and board.

1.2. Hemp

Hemp fibre is subjected to a genetic selection process to ensure that the chosen varieties present a low quantity of THC, the main psychoactive constituent of cannabis (under 0,2%), an amount supported by the European Union (López 2018). These fibres contain lignin, which provides strength and resistance, and the absence of proteins avoids the attack by insects. Since these fibres are renewable, biodegradable and grow fast, hemp is considered a sustainable material. The life cycle consists of the growth of the plant for more than a hundred days and the extraction of the fibres by moisturizing the plant (*Tipos de aislantes. LANA DE CÁÑAMO 2020*).
It is durable, comfortable and presents an ecological process without requiring chemical agents throughout it (Rodríguez 2014). In addition, it allows the recovery of the soil where it is produced thanks to its herbicide effect (Cannabric 2008).

Figure 3. Hemp: blanket.

1.3. Sheep wool

Most of the raw material comes from shearing sheep, what is a necessary process in the life of sheep that should occur every year. This means that the basic element is naturally designed to provide thermal comfort while being elastic, hygroscopic and able to breath. Shearing one sheep can provide three to five kg of wool that should be transformed by bleaching the wool with a borax salt treatment after removing the dirt by washing it in hot water. Then, a 15% of polyester binder is added to gather all the fibres and the thermal insulator is ready to be implemented (T*ipos de aislantes. LANA DE OVEJA 2020*).
The final product is renewable, recycled and recyclable and contributes to improve the environment in a social aspect by helping to develop the wool sector (*RMT-NITA WOOL* 2020).

Figure 4. Sheep wool: in bulk & blanket.

1.4. Cotton

The thermal insulators derived from cotton are obtained from recycled textile products, thus, the raw material is not totally natural but it is completely recycled. The transformation process consists of a shredding operation to extract single fibres that are later gathered into a multi-fibre product.
For this particular material, the ecology of the process can only be guaranteed in the production but the whole process is sustainable in time. Cotton insulators need a special treatment to resist fire, fungi and insects and help to reduce the production of emissions and waste (*RMT-NITA COTTON* 2020).

Figure 5. Cotton: in bulk & blanket.

1.5. Cellulose

Once again, the origin of the basic material is not natural but recycled. It consists of newspapers that have not been sold. The whole transformation process is based on collecting newspapers to transform them by means of grounding and borax treatments into a bulk thermal insulator (*RMT-NITA CELL* 2020).
This alternative presents great resistance to biological attacks while helping to create dry environments where it is incorporated. Cellulose insulators also provide great comfort and acoustic performance thanks to their thermal lag (8-12h) (AISLAnat 2020).

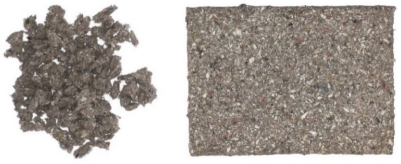

Figure 6. Cellulose: in bulk & blanket.

1.6. Wood fibres

Grinded wood is the raw material used to produce this thermal insulator. Forestry and wooden industry generate wastes in form of sawdust and cutting pieces that are transformed by means of grinding and shredding either in a wet or a dry process.
Wood fibres insulators are comfortable, ecological and sustainable. Their temperature is stable before temperature variations and are suitable to be implemented in almost every constructive system. However, they are mainly produced out of Spain (GUTEX 2020).

Figure 7. Wood fibres: in bulk & blanket.

2. RESULTS

The following table contains the fundamental technical and environmental features to understand the behavior of each material. The R-values and U-values have not been included for space, as they can be approximated from thermal conductivity.

		Technical features							Environmental features		
		Density ρ (kg/m³)	Thermal conductivity λ (W/mK)	Hygroscopicity (% of its own weight)	Water steam diffusion Sd (m)	Thermal diffusivity α(m²/s)	Fire resistance (class)	Price (€/m²)	Energy (MJ/kg)	Emissions (kgCO₂/kg)	Biodegradable
Cork	Board	100	0.037	7	4.20	2.22 E-07	E	14.82	7.54	-1.72	Yes
	In bulk	65	0.040	7	4.20	3.68 E-07	E	10.55	6.75	-1.70	Yes
Hemp	Blanket	30	0.041	17	0.50	5.94 E-07	F	7.10	-	-0.62	Yes
Sheep wool	Blanket	14	0.043	33	0.50	1.81 E-06	F	7.50	18.92	1.55	Yes
	Board	35	0.035	33	0.40	5.88 E-07	F	10.29	16.64	1.45	Yes

Table 2. Technical and environmental features.

CONCLUSION

In this section, the conclusions extracted from the analysis and comparison of different traditional and alternative thermal insulators are presented, with respect to their technical and environmental features. The outcomes are divided in two parts, according to the insulator format. This decision responds to the different implementation in each case. The thermal insulators in bulk are generally used to be insufflated inside an air chamber while the blanket and board formats are meant to be attached vertically to a layer of the façade. The best in bulk insulators in a global scene are granulated cork, wood fibres and cellulose. While cork outstands due to its environmental factors, such as the fixation of CO_2 during its process (-1.70 $kgCO_2/kg$), wood fibres show better technical characteristics is aspects like the thermal conductivity (0.038 W/mK). However, cellulose insulator presents great performances in both fields and has a really competitive price (2.12 €/m^2). Regarding technical values, its thermal conductivity (0.038 W/mK) is one of the lowest of all the studied materials. It has a good hygroscopic behaviour (30%), an optimal behaviour in terms of thermal diffusivity and its fire resistance is type B. Environmentally speaking, cellulose presents a low energy consumption (5.55 MJ/kg) and a negative value of CO_2 emissions (-0.65 $kgCO_2/kg$). A quite surprising outcome of the study is that the price of the traditional insulator materials, which was supposed to be one of their biggest advantages, appears to be at the same level as some alternatives. In relation to board and blanket formats, the best options are wood fibres blanket, cork board and cotton both in board and blanket. In this case, each of the mentioned materials outstands for a reason. The wood fibres blanket presents one of the lowest prices (4.62 €/m^2) while cork board insulator presents excellent environmental features such as its negative level of CO_2 emissions (-1.72 $KgCO_2/kg$). With regard to blanket and board cotton, both present similar features. Blanket format stands out due to its low price (6 €/m^2), while board format is preeminent in relation with the thermal conductivity (0.034 W/mK). Nevertheless, both of them show comparable hygroscopic behaviour, with one of the higher values of the analysed materials (24%). Their water steam diffusion is optimal while their fire resistance is class F, the lowest. Concerning environmental performances, the energy provided during their life process is 9.69 MJ/kg and their level of CO_2 emission reveals one of the lowest values with only 0.7 $kgCO_2/kg$. Furthermore, due to their vegetable origin, they are biodegradable and recyclable materials. As a result, it is possible to acknowledge that due to its great balance between environmental behaviour, low price and good thermal conductivity, cotton thermal insulator is the most complete of the studied alternatives. Ultimately, this research can confirm that the best sustainable alternatives to traditional thermal insulators are cellulose in bulk format and cotton both in blanket and board.

BLOCK 6: RESTORATION, CONSERVATION AND RENOVATION

PAPER #6.01

RESEARCHES AND PROJECTS BETWEEN CONSERVATION AND RENOVATION FOR THE FUTURE OF THE CITIES

Stefano Francesco Musso[a], Giovanna Franco[a]
[a] Architecture and Design Department, University of Genoa, Genoa, Italy

ABSTRACT

The paper proposes the synthesis of some recent research experiences carried out by the authors, in Genoa and Liguria Region. These researches, committed by public authorities (Ministry of Cultural Goods and Heritage, Regional Department of Culture) and public owners (the University of Genoa among others) are both theoretical and applied to single buildings or architectural complexes. Objects of the researches are, in some case, ancient monuments (in need of restoration, re-use and renovation) located in the consolidated tissue of the contemporary city. In other cases, we worked on Architectures belonging to the Modern Movement, spread off in our whole region that need to be known and appreciated by the community, as first, in order to be conserved and reused respecting their architectural, constructive, historical and social values. All the researches show a high interdisciplinary interaction and collaboration among experts in architectural restoration and conservation, consolidation of traditional buildings, history and archival researches, building physics, chemistry, ICT and digitalization, energy efficiency, thermal enhancements and technical equipment. These works have led to important operative consequences in terms of safeguarding, restoration, renovation and re-use, through the social engagement of local communities, with significant impacts on the future of the contemporary city. To quote some examples, we worked on the monumental complex of the "Albergo dei Poveri" in Genova (almost 60.000 square meters of total covered surface, built from XVII to XIX C.), preparing a general masterplan for its complete reuse and restoration (for crowdfunding). Another real case has been the historic palace Belimbau (one of the most important of the "Rolli Palaces" dating from medieval age and transformed since XVII C.). Thanks to our researches, the University obtained in this case some funds to restore the monumental rooms and open them to the city. We also worked on the ancient former church of the Jesuits' college (XVII C.), now abandoned and in need of a future destination and on the Prince Andrea Doria's Palace, one of the major Renaissance Villas in Genoa and, recently, on the Doge's Palace, in the heart of the city. Ancient and recent buildings are essential parts of the collective memory of the contemporary cities and built landscapes. Their permanence and transmission to the next generations are thus essential for a conscious, creative and not oblivious future and for human well-being. The paper deals with all these aspects going beyond the single case studies.

KEYWORDS

Conservation; renovation, cultural heritage; interdisciplinarity; digitalization.

INTRODUCTION

The expansion, for fields of interest and meanings, of the term "heritage", as suggested by the Italian Code of Cultural Heritage, leads not only the scientific community to question the values (testimonial, historical, economic, social and of other nature) conveyed by ancient but also

by recent and even very recent architectures. In this perspective also their fate and their protection, enhancement, redevelopment or, conversely, their definite oblivion and destruction, are nowadays on the fore as a matter of discussion. The continuously expanding universe of artefacts to which conservation and restoration necessarily turn their attention is in fact extraordinarily rich, for historical, constructive and formal variations, in time and space, and it escapes any claim of total and autonomous domination by a single discipline and, even more by individual technical operators. In fact, the forms and spaces of the artefacts change, according to the resources, places and historical moments of their realization, as well as their constructive principles, the techniques of working materials, the executive or installation devices adopted by blacksmiths, bricklayers and carpenters, belonging to the different material cultures involved. The causes of the processes and of degradation phenomena that afflict the buildings are also very changeable, from place to place, from time to time and from building to building, and this outlines a universe of very vast and complex problems that no single expert can face alone. We must therefore ask ourselves, since there is no answer that is valid forever and for everyone, whether we recognize and want to take those elements of our heritage as a real legacy of which to take care of, with the contradictions and shadows that every process of "patrimonialization" brings with itself. For this reason, it is necessary to raise the level of training, to allow future professionals and technicians to handle the increasingly complex demands and problems posed by contemporary society in regard with the fate of our heritage(s). The paper briefly illustrates the structure and the training objectives of the School of Specialization in Architectural Heritage and Landscape of the University of Genoa (Master-post-Master Programme), its links with the main cultural institutions and local and national bodies in charge of tutorship and safeguarding, its relations with advanced research activities and its impact on education.

1. RESEARCH AND INTERVENTION ON CULTURAL HERITAGE

1.1. An interdisciplinary path of higher education

The post-graduate training course of the School of Specialization responds to the extreme complexity of the field of architectural restoration, that involves many specialists. Among them are surveyors, analysts, chemists, physicists, technicians of different kind, restorers, expert in the various materials and constructive elements involved, structural engineers, historians, art historians and experts in artistic techniques and many others. The School, therefore, trains professionals characterized by a strong technical profile, rich in articulated and complex skills and competences but, above all, in those of cultural nature, rising their awareness and ability to rule the many aspects, sometimes even conflicting, that characterize this delicate field of study, design and practical work.

The School of Genoa has therefore a strong multi-layering and operative imprinting and the curriculum with the organization of teaching activities follow the phases and the sequence of operations that characterize a real restoration project, albeit in the "didactic" time of the two years of the course. In order to strengthen this objective, the final thesis also retraces the same analytical and planning path, put to the test in the "professional time" of about six months.

The teaching courses cover, in their articulation, the fundamental scientific, technical and cultural guidelines of restoration, nevertheless overcoming the apparent and rigid separation between the

two years of the course. The frontal teaching, the laboratory and practical experiences are therefore oriented to the acquisition of knowledge, skillsand competences necessary to carry out and to control the main and most common non-destructive analysis and diagnosis techniques on the material consistency of buildings and their behaviour over time. This involves a strong focus on documentary and archival investigations and rigorous architectural survey (through traditional and innovative techniques). Aside these, strong attention is given to chemical and physical, mineralogical-petrographic and technical-mechanical characterization of materials. Also the evaluation of the spatial and morphological characteristics of buildings, according to their potential use and compatible reuse, is crucial, as well as the exam of their technological and construction components, the analysis and diagnosis of decay phenomena, of structural instability, as well as of the environmental conditions that affect their consistency, stability, functionality and durability. Further, the School provides the knowledge and the necessary skills to design and coordinate the various forms and phases of intervention on existing buildings: from the preliminary design (of technical-economic feasibility) to the final and detailed one, including the methods of management of the entire building process. This includes the use of ICT tools, the knowledge of the construction phase, the direction and final assessment of the works, as well as the attention for fate of the restored good (planned maintenance and conservation, modes of use, management models). Within the didactic activity, at least one full day every week is dedicated to an "Interdisciplinary Laboratory". The laboratories are the instrument, the space and the occasion for outlining a path, guided by teachers, throughout the analytical-diagnostic inquires and elaborations, in the first year, and the design phases, in the second one. All activities regard a specific artefact and site, chosen in agreement with the bodies in charge of the protection and safeguard of cultural heritage or other local authorities, because of their cultural interest and on which they really intend to intervene with a restoration. By working on the selected artefact, the students have the chance to develop some clearly finalized studies and to elaborate on their basis a project characterized by correct proposals and feasible technical solutions for real needs. Moreover, the design choices must be culturally aware and coherent with the laws and regulations in force on the subject, with the different and often contradictory demands of protection, conservation, use and compatible re-use, environmental sustainability, improvement of energy and seismic behaviour, valorisation and future management of the restored good. Particular attention, during the first year of the programme, goes anyway to the use of information and communication technologies (ICT) for the cataloguing and management of data acquired during the study phases.

At the end of the first year, the students will acquire the following knowledge and develop the corresponding competences and skills:

- understand the architectural artefact, through the related studies of its geometries, building elements and materials, surfaces, structures and stability, spaces, accessibility, usability, functions and safety;
- understand the transformations of the building over times, relating the results of historical reconstructions from indirect sources and those deriving from direct archaeological analysis;
- evaluate the state of conservation of the building, as a whole and in its individual parts and construction components, recognizing phenomena of decay, damages, failures, deficits affecting materials and installations, construction elements, systems and structures;
- identify the causes and extent of damage, failures and deficits, assess the

vulnerability and level of exposure of the good to the aggression of environmental factors and related risks of different nature;
- assess the compatibility between the functions and current uses, the characteristics of the available space, the characters of the structures and the primary needs of conservation;
- manage sets of information of various kinds, complex, heterogeneous and evolving in time, through relational databases and, in general, digital data management systems (GIS, BIM, …);
- Identification of adequate criteria and guidelines for the design of the interventions of conservation, restoration and redevelopment of buildings and spaces of cultural interest.

The second year faces the elaboration of the real restoration project of the building object of interest during the first year. At the end of the second year, the student should therefore acquire the following knowledge and develop the corresponding competences and skills:
- consciously and critically use the results of the studies and of the analytical and diagnostic phases developed during the first year and integrate them where necessary;
- identify the general objectives of the project of restoration of the involved building and the strategies to pursue through a gradual focus (from the programmatic phase to the technical final report of the project and its graphical-digital and administrative elaborates);
- motivate the project's choices with reference to the contemporary methodological, disciplinary and cultural debate and to some similar significant examples of interventions carried out in recent years;
- adapt the project to the regulations (related to earthquake's resistance improvement, fire-proof, overpassing of architectural barriers, containment of energy consumption, ...), identifying solutions consistent with the conservation objectives, respecting the specificity of the protected property;
- choose the type of installations (heating, cooling, lighting, air treatment) necessary and most suitable, in relation with the conditions of use of the building, the needs of conservation and enhancement of the property and the current standards of regulation and comfort;
- choose the most appropriate materials, techniques and products for the restoration interventions, based on the specific needs of the building, the surrounding environmental conditions, their technical and commercial characteristics, in a cost-benefit conscious budget.

1.2. The Laboratory of Analytical Methods for Restoration and History of built Heritage (MARSC)

The teaching of restoration in the School of Genoa can count on the technical and operational support of the Laboratory of Analytical Methods for Restoration and History of the Built (MARSC Laboratory of high qualification of the University). The Laboratory comprehends three sections: dedicated to: analytical methods for architectural survey, archaeology of architecture and characterization of materials.

Among the research activities and the fields of applications developed by the section dedicated to the survey we can remember:
- rigorous longimetry for the three-dimensional survey of architecture and and solid modelling;
- topography for architecture;
- the rigorous analytical and digital, flat and three-dimensional analytical photogrammetry;
- simple and mosaic rectified photos for the relief of flat surfaces (ortho-photos), also deriving from clouds of points obtained through the use of laser scanners or with structure from motion techniques;

- advanced information systems for the management of the restoration project (interoperable relational data-bases, GIS, BIM, WEB-GIS);
- the treatment and quantitative analysis of digital images for the recognition of materials and decay phenomena and the simulation of the expected results of the restoration interventions;
- the construction of repertoires and repositories of adequate techniques of intervention in restoration.

The second section of the Laboratory, dedicated to the Archaeology of Architecture, is the development of the laboratory founded at the end of the 1980s by Tiziano Mannoni and is dedicated to the study of the constructions of the ancient and recent past, in their quality of direct "material sources". The section developed many methodological and applied researches within the field of stratigraphy and archaeology of architecture to reconstruct the history of the buildings and to date its materials and constructive elements. Also important are the analysis of documentary sources and the analysis of decay phenomena and structural instability conducted according to a historical perspective, in order to provide restoration designers with extensive and integrated elements of knowledge and evaluation in this field.

The third section of MARSC, is devoted to the study and characterization of the materials employed within buildings of historical and cultural interest. The areas of research regard the pre-industrial production of binders (with particular regard to dolomitic limestone), the formation of lumps in lime mixes, the role and characteristics of hydrating agents in mortars. The production and processing of iron in pre-industrial times, with attention to its structural use in tie rods is as well a research theme with the use of pigments in fresco and dry colouring

2. EDUCATION AND RESEARCH: A NECESSARY COMBINATION

Alongside the traditional educational activities, the School reserves adequate space for practical experimentation, proposing to the students an intervention of restoration and reuse of buildings and sites of cultural interest, based on real needs. The buildings and sites for each year's work belong to historical centre of Genoa or the Liguria Region that require conservation, consolidation, restoration, and enhancement and eventually a compatible re-use. In agreement with the public or private owners of the selected buildings, the students work on the analytical and diagnostic phases (first year) and in the elaboration of design hypotheses in the second year, as already mentioned. Much of the matters thought can thus be immediately reflected in the design activity, with contributions by many specialists in subjects like technical installations and equipment, safety and accessibility requirements, lighting solutions, energy saving and comfort improvement. The projects reach the definite level and executive details with the necessary technical and estimative documentation.

The buildings or monumental complexes described in the following paragraphs have been the subject of research funded at national or local level, and represented for the students the occasion to achieve methodological, technical and cultural advancements.

2.1. The Doge's Palace of Genoa: prisons and the "Grimaldina tower"

The Doge's Palace, currently the heart of the city's cultural life, was the seat of the first Genoese Doge, Simon Boccanegra, during the early medieval age. The first Palace incorporated different pre-existing buildings, in a glorious moment of the Republic of Genoa, after the victories against the Pisans (1284) and the Venetians (1298) that gave Genoa the supremacy within the Mediterranean basin.

The so-called "Grimaldina Tower", between XII-XIII centuries, knew some transformations and the addition of a new floor in the first half of the 16th century. Between the 14th and 15th centuries, the Palace enlarged, until it reached a closed configuration along the four sides of an inner and secluded courtyard (now Piazza Matteotti). The succession of the porticos and courtyards and the covered atrium belong to the 16th century constructive phase due to architect Andrea Ceresola, known as "Vannone" who designed and built also the monumental double staircase leading to the main noble floor. In 1777, a great fire almost completely destroyed the palace and architect Simone Cantoni, who also came from Ticino district like Vannone, was committed to rebuild the damaged parts among which the great rooms of the Maggiore and the Minor Consiglio, on the first floor with their covering structures and the Doge's apartment. He adopted for the roofs a solution characterized by parabolic arches in bricks, without using wooden beams (still surviving in the Minor Consiglio), thus preventing the risk of a new fire. The Grimaldina Tower is, together with the Lantern (the medieval lighthouse of the harbour), a string symbol of the political power of the Oligarchic Republic. Its inner spaces, together with others located above the Doge's Apartment, were in the past a jail where also famous prisoners were imprisoned along the centuries (Niccolò Paganini, Jacopo Ruffini...). The objective of making the spaces of the Tower accessible and ready to host a small museum (exhibiting objects found during the restoration works of the 90s of the 20th century) required the students undertake a refined analytical and design path throughout so many and precious signs of the history and memory of .the city. In this way, the School will answer to the needs expressed by the Direction of the Foundation of the Ducal Palace contributing to a wider social use of this monument of the city.

Figure 1. Doge's Palace, the Salone del Maggior Consiglio. Source: (G. Franco 2020)

2.2. Former Church of SS. Gerolamo and Francesco Saverio, former seat of the University Library of Genoa

The Church of the Jesuits' College of Genoa, currently hosting the Rectorate of the University, was built in the mid-seventeenth century by the nobleman Francesco Maria Balbi on the ruins of an older church, adjacent to the convent of the nuns of St. Augustine. The church, with a single nave and four side chapels (partly added afterword), was decorated with frescoes by Domenico Piola, one of the most important painters of the period.

With the suppression of the Society of Jesus (1773), the Republic of Genoa assigned the College and the Church to higher educational institutions; at the beginning of the 20th Century, the former church was transformed into the Natural History Museum of the University. In 1915, the "Casa del Soldato" (Soldier's House) was installed in the Rectorate also using the former church, which knew afterwards further transformations (insertion of side galleries). In 1926, Eng. Arch. Carlo Fuselli presented the first project for the insertion of the University Library inside the church; the project aimed at the division in height of the nave thanks to a new reinforced concrete ceiling at the base of the vaults, to create the books' stores below and the reading room above it. After of Fuselli' death the Superintendence for Monuments, in 1934, committed to architects Mario Labò and Giuseppe Crosa di Vergagni the design of the

University's library inside the former church, to recover and ameliorate the works already realized. The Library was inaugurated in 1935 and, in 1947, it was transferred to the state's property.

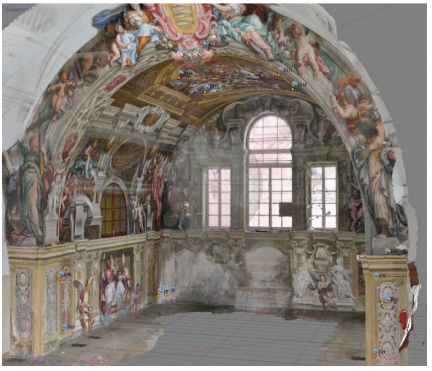

Figure 2. Frescoed apse in the former church of Saints Gerolamo and Francesco Saverio. Elaboration of the photoscan survey. Source: (MARSC 2019)

In 1966, the complex of the former Jesuits' collegium with its church was recognized as of "Cultural Interest", according to Law 1089/39, "because it preserves the original 17th century façade and, inside, valuable frescoes by Domenico Piola in the apse area". Following the recently completed transfer of the University Library to another location (the former Hotel Columbia, via Balbi 40), the church has been closed to the public since 2014 and is currently abandoned, in needs of conservation and restoration interventions with new compatible uses. The School is now working to support the local Superintendence in this perspective thus giving a real contribution to the City development.

2.3. Villa of Prince Andrea Doria in Fassolo, Genoa

The "Palazzo del Principe Andrea Doria" (the winner of Lepanto's naval battle against the Turks), built during the first half of XVI century incorporating some pre-existing buildings, is one of the largest and most important noble residences of the Renaissance age in Genoa. The Villa is known for a significant decorative cycle, realized by Perin del Vaga, Raphael's best pupil. The monumental complex, that comprehend a Italian-style garden towards the sea (with a private landing place, no more existing) and a romantic park (now completely disappeared) towards the hills on the back, was enlarged by Andrea's heir, Giovanni Andrea I. Today, the Palace still houses the Doria Pamphilij family and a museum full of masterpieces of art. The eastern wing of the Villa, partly unused, contains spaces of considerable interest, partly belonging to pre-existing residences. The students of the School of Specialization consulted public and private archives, recovering many documentary and iconographic sources about the history and transformations of the complex. They also realized a rigorous topographic and laser-scanner survey and studied the material consistency of the artefact, its constructive techniques as a primary and direct source of information about its history. This allowed us to re-write a history almost completely unknown to the city, even if it is in a focal and a crucial point of it. The Trustee Florida Doria Pamphilj that manage the complex asked

Figure 3. Villa of Prince Andrea Doria, XVI Century. Source: (G. Franco 2018)

the School to develop these researches and to provide some design suggestions for the restoration and the compatible-sustainable re-use of its east wing and its valorisation for the entire city.

2.4. "Belimbau Palace", Genoa

The Belimbau Palace, located in the heart of the ancient city and at the junction between "Piazza della Nunziata" and "Via Balbi", belongs to the system of Rolli palaces destined to host the most illustrious guests of the Republic of Genoa. It belonged to noble families until the end of the 20th century when their last descendant left it to the University of Genoa, which is now taking care of its complete restoration and reuse. The Palace was built at the behest of the nobleman Francesco De Ferrari at the end of the 16th century by incorporating some pre-existing buildings and the rests of the medieval aqueduct still visible in the body of the façade. The pictorial decorations by Lazzaro Tavarone (pupil of the great painter Luca Cambiaso who ended his life in L'Escorial in Spain) are among the most important of the XVII century in Genoa. The frescoes decorate the vaults of the atrium, of the staircase, the entrance loggia and the main room of the first noble floor (with one of the first representations of the natives of America and of Christopher Columbus kneeling in front the Queen and the King of Spain coming back from the Americas). Between the end of the 18th century and the early 19th century, the Palace underwent a major renovation of the monumental staircase and of the main façade. Over the centuries, the Palace knew several fragmentations into single apartments and suffered many modifications that make now difficult to read and completely understand its original configuration. Together with the Head of the Technical Office of the University and under the supervision of the teachers, the students of the School conducted many analytical and diagnostic activities aimed at better understanding the evolution of the Palace and its current state of conservation. The materials thus produced and the knowledge acquired thanks to them made it possible to obtain some funding by the Italian Government for the restoration of the monumental spaces of the palace, for its future public use.

Figure 4. Belimbau Palace. Elaboration form photo-scan and laser scan survey. (Laboratory MARSC 2017)

2.5. Albergo dei Poveri, Genova

The "Albergo dei Poveri" (the Poors' Hostel) in Genoa is a vast welfare complex dating from the middle of 17th century, built outside the city walls, radically modifying a natural valley. It was built for philanthropic purposes (at the behest of the nobleman Emanuele Brignole Sale) but also as a sort of seclusory for poor people. The complex, afterward incorporated into the expansion of the modern city (after the demolition of the city walls in the first half of XIX century), lost its original role and was definitely abandoned in the late Nineteens of XXth century. The complex, in force of a loan, is now in the hands of the University that is in charge of its management and already restored and reused about 30% of its covered surface for the departments of humanities and law and their didactic spaces. However, an exact knowledge of the physical state of the structure and its spaces was missing until recent years. The School of Specialization, on behalf of the Rectorate therefore concentrated the teaching activities for some years on the study of this vast and very important

architectural complex. It has been also a case study within a Research Programme of Significant National Interest (PRIN 2010-2011). It investigated the possibility that the computer tools of parametric nature, that facilitate the management of cognitive,design and management data, could be adapted to the needs (theoretical, cultural, technical and operational) of a complex reality such as an architectural and urban monument of ancient formation and stratified consistency like the Albergo. The School thus developed rigorous architectural surveys (topographic, longimetric, digital photogrammetric, Z-scan, laser scanner, Structure from Motion), a BIM and a GIS information system, for the collection and archiving of the numerous data collected. The constructive characteristics and the macro-conditions of conservation of the complex were as well investigate and recorded alongside the identification and location of the most relevant risk factors, the correlated most urgent interventions, the functional layout for the entire complex and some design hypotheses on single parts related to new possible and compatible uses. Thanks to these studies and design explorations, several new restoration interventions are now going on.

CONCLUSION

The few quoted examples of studies carried out during the years by the School of Specialization show how the University can provide real and effective contributions to the future life and quality of the contemporary cities. Knowledge and technical or professional expertise are in fact necessary for any intervention, at any scale, on the continuous material palimpsest of our cities, very often multilayered not only in material terms but also in symbolic end social ones. The quoted buildings, as many others, ancient or recent, are essential part of the collective memory of the local communities if recognized of cultural, architectural, historical and social or economic value. Their fate thus depends first on their knowledge and shared appreciation among the citizens. On this level lies a first fundamental filed of commitment for the University. We can/must in fact spread of the knowledge we can acquire whilst educating and training future professionals culturally aware and technically strong and ready to face the many challenges the destiny of these or other buildings, in strict connection with the entire urban fabric they belong to. Then University can support their public and private owners in looking for the necessary economic resources for restoring, enhancing and correctly re-using them in order to be still part of the city's life. Further University can provide several forms of design explorations of possible solutions, thus increasing the quality of the whole process, from the planning scale to the real construction sites. University can and must thus play a real role for the future of our cities.

PAPER #6.02

A BIBLIOMETRIC REVIEW OF LIFE CYCLE RESEARCH OF THE BUILT ENVIRONMENT

Ming Hu[a]
[a] University of Maryland, College Park, Maryland, USA

ABSTRACT

Life cycle assessment (LCA) has been used as an analysis tool to help decision-makers plan for mass urbanization and building construction; however, the research to date focuses on either the individual building scale or overall urban scale. Although several methodologies have been applied to both scales, the results have not been reconciled or synchronized. In light of this, this paper first presents a systematic literature review using bibliometric network data to assess state-of-the-art knowledge of the use of LCA at different scales from 1990–2017. Second, the paper identifies the main research foci at the building and urban scales. At the building scale, three research focal points are identified: building materials and products, design solutions, and energy consumption/ emissions reduction. At the urban scale, there are three research areas of focus as well: urbanization and infrastructure planning, urban metabolism (water/energy/ waste synergy), and complexity of urban issues. Next, the most influential papers and journals are presented. Drawing upon the findings from the literature review, major gaps in current research activities are identified as the building-centric approach, energy performance–centric approach, and lack of consideration for uncertainties. These are critical areas requiring further study and research

KEYWORDS

Life cycle assessment; literature review; urban scale; building scale; bibliometric network data.

INTRODUCTION

Addressing the ecological impacts of the built environment requires an understanding of global trends in the building sector. Life cycle assessment has been used as an analysis tool to help decision-makers plan for mass urbanization and building construction; however, the research to date focuses on either the individual building scale or overall urban scale. Although several methodologies have been applied to both scales, the results have not been reconciled or synchronized. Many studies have centered on quantifying environmental impacts at the building scale (Utama et al. 2009, Treloar et al. 2000, Fay et al. 2000, Utama et al 2008, Li et al 2011, Wang et al. 2005, Bribian et al. 2009), and robust methodologies have been established and developed. At the urban scale, certain methods have been implemented and tested to quantify the ecological impact of large built environments that include multiple buildings (Stephan et al. 2013, Kennedy et al. 2011, Davila and Reinhart 2013). However, assessments of environmental impacts of buildings and urbanization have been largely confined within their own singular scales. An overview of research activities, foci, and trends is the first step to creating an integrated framework to understand the environmental impacts of the built environment. A review of cutting-edge knowledge in the life cycle assessment (LCA) approach and studies on the built environment is meant to (1) identify the main research areas within each scale, (2) gain insight into the size of the different research focal points, and (3) identify any research gaps.

1. RESEARCH METHODS AND TOOLS

Bibliometric research is a research technique for studying science-based citation data, which originated in the early twentieth century. Citation analysis (CA) and Co-citation analysis (CCA) are very well- established branches of bibliometric research that are used to evaluate the relative importance or impact of an author, article, or journal. Since citation frequency reflects a journal or article's value, citation analysis can be conducted to establish the impact of a particular study and identify the research focus and pattern, based on citation patterns (Garfield 1972, Narin 1976, Moed 2006, Harzing et al. 2008, DeBellis 2009). Applying mathematical and statistical models in CA and CCA are primary techniques that are used to date. Rapid changes in digital technology have introduced new techniques and methods that are used in bibliometric research to capture large amounts of text data available online. For example, Text data mining (TM) is a fast-developing technique that extracts critical information from unstructured datasets—unlike citation. TM techniques involve information retrieval, text analysis, information extraction, clustering, visualization, machine learning, and data mining (Nagarkar et al. 2015). TM is particularly viable in a multidisciplinary research where co-citation patterns appear to be difficult to decipher. Integrating TM in citation and co-citation analysis helps researchers to process unstructured information, such as abstracts from a thousand papers, in the matter of a couple seconds and extract the meaningful numeric indices from the text, eventually feeding them into statistical and machine learning algorithms. Using machine- learning algorithms, the information derived from a large text dataset could be used to form meaningful and rational summaries or conclusions based on the words contained. This method/technique could be used on clusters of words or to determine the relationship between words. Put simply, text mining turns words into numbers that can be computed and analyzed.To analyze and interpret the results from CA, CCA, and TM, maps are often constructed to help visualize the data. For this project, VOSViewer was chosen for its two-dimensional distance-based map (Moed 2006). VOS stands for "visualization of similarities" and aims to locate words in a low-dimensional space in such a way that the distance between two words reflects the similarity or relatedness of the words as accurately as possible (Van Eck et al. 2009). VOSviewer constructs a map based on a co-occurrence matrix and consists of three steps. The first step is to obtain a similarity matrix; in the second step, a map is constructed by applying the VOS mapping technique to the similarity matrix; then, in the final step, the map is translated and reflected. In a VOS-constructed map, different cluster maps represent different research foci; the sizes of the nodes indicate the relevance of the items—including research topics, authors, sources, or countries—and the distance between nodes illustrates the intellectual connections.

2. THE HOME-WORK LINK

VOSviewer map was used to determine influential studies, thinkers, and concentrated research topics and their correlations. In order to identify the research areas of focus, a term map was created based on a corpus of scientific publications. The corpus of scientific publications includes 1,063 articles found in Web of Science (WOB) from 1990–2017 using the key search words, "life cycle assessment," "life cycle analysis," "buildings," and "architecture." The co-occurrence frequencies of terms (text) were determined based on a minimum of 20 occurrences of a term, and out of the 22,459 terms, 315 meet the threshold.

For each of the 315 terms, a relevance score was then calculated. Base on this score, the most relevant terms were selected, with the default choice in the program being to select 60% of the most relevant terms. Altogether, 189 terms were selected for LCA research at the building scale, with the results shown in figure 1. Based on VOSviewer clustering techniques, the terms in the dataset were divided into three clusters, with the colors indicating the different research clusters and the adjacency of nodes from different clusters suggesting the intellectual connection of different fields.

• Cluster 1 (blue): building materials, products, environmental assessment, impacts (left)

• Cluster 2 (red): design solutions/costs, sustainability/criteria, framework (right)

• Cluster 3 (green): energy consumption, emissions, reductions (lower)

These clusters represent three major research focal points: *building materials and products, design solutions, and energy consumption and emissions.*

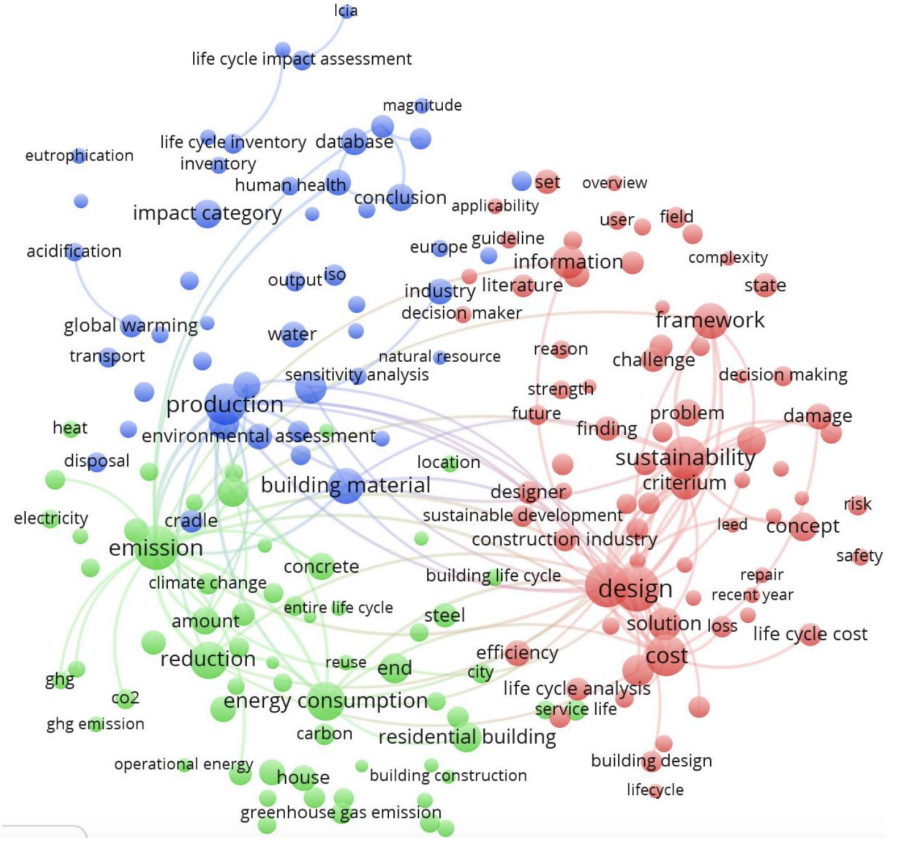

Figure 1.Term map representing the main research areas of LCA at the building scale

Cluster One: Building Materials and Products

The majority of building materials studied in academic publications concentrate on conventional materials used for base building, such as concrete and steel framing. Concrete and steel account for 20–35% and around 12–22%, respectively. Together, steel reinforcement bars and concrete account for 50–80% of the environmental impact from buildings. Consequently, one of the basic ingredients of concrete— cement—has been studied extensively. It accounts for 4–5% of overall CO2 emissions from the building industry (Chau et al. 2007, Guggemos and Horvath 2005, Bribián et al. 2009, Wu et al. 2005). Other common building materials that have been researched are brick and wood (Tettey et al. 2014). Koroneos and Dompros (2007) used data provided by a local brick manufacturer, together with published references, to study the brick production process and identify possible areas for improvement in brick production. Additionally, Ximens and Grant (2012) quantified the greenhouse benefits of wood products and found that replacing all floors and sub-floors with timber could reduce greenhouse gas emissions from buildings. Jönsson et al. (1997) studied different kinds of floor materials—including wood, vinyl, and linoleum—and concluded that solid wood appeared to be the most environmentally preferable material. The most commonly used building materials have not changed for decades, and, following 2014, there has not been much grounding-breaking LCA research about building materials. The only new, advanced material to become a research focus in the past three to five years has been nano-materials—phase- change materials and their application as paint, coating, and building envelope materials.

Cluster Two: Design Solution

The second area of focus is architectural design, which includes location, orientation, building façade design (glazing ratio), building density and massing, and related sustainability criteria. Pacheco and team members studied different design factors—such as building compact factors, orientation and shape, and building envelope—and concluded that the factors with the greatest repercussion on the final energy demand were building orientation, shape, and the ratio of the external building surface to the building volume (Pacheco and Martínez 2012). Building orientation and shape are major design decisions made in the early design stage that cannot be reverted; therefore, integrating the concept of LCA in the early design stage will help the design team to find an optimized solution for building performance while minimizing the environmental impact. Even with active research in this area, the knowledge translation has been slow. While there are several quite robust design codes for building mechanical system optimization (occurs in a later design stage), such as the ASHRAR standard, there is a lack of systematic design guidelines focused on architectural design optimization. Consequently, the opportunity to translate the research findings into practical design solutions is tremendous.

Cluster Three: Energy Consumption and Emission Reductions

This area is expected to produce results since energy consumption has a direct correlation with emissions reductions, and it is the only overlapping research focus in both the building and urban scales. This research focal point examined the construction process, operation phase, and building material-acquiring phase, and results reveal that the energy consumed during the construction phase accounts for a very small percentage and, therefore, has little environmental impact on the entire building life cycle. The main influential phase is the building operating phase, and the largest environmental impact, CO2 emissions, is associated with the operating energy (Flower and Sanjayan 2007, Norman et al. 2006, Fuller and Crawford 2011,

Jiao et al. 2011, Jones and Kammen 2014, Glaeser and Kahn 2008). The second most important consumption category is embodied energy. Venkatrama Reddy and Jagadish estimated the embodied energy of a residential building consisting of different low-energy materials and obtained a 30– 45% reduction in embodied energy (Jones and Kammen 2014).

3. FINDINGS - URBAN SCALE

The process used in section 3.0 was repeated to identify research focal points of LCA at the urban scale. The corpus of scientific publications that included the 340 articles from WOS was used to create a term map, with the keywords used in the search being "life cycle assessment," life cycle analysis," "urban," "city," and "district." The size of research activities at the urban scale is substantially smaller than those at the building scale; therefore, less occurrence frequency was used to create the term map. The co- occurrence frequencies of terms (text) were determined based on a minimum of 10 occurrences of a term. At the end, 296 out of 13,218 terms met the threshold. For each of the 296 terms, a relevance score was then calculated. Based on this score, the most relevant terms were selected, with the default choice in the program being to select 60% of the most relevant terms. Altogether, 178 terms were selected for LCA studies at the urban scale,

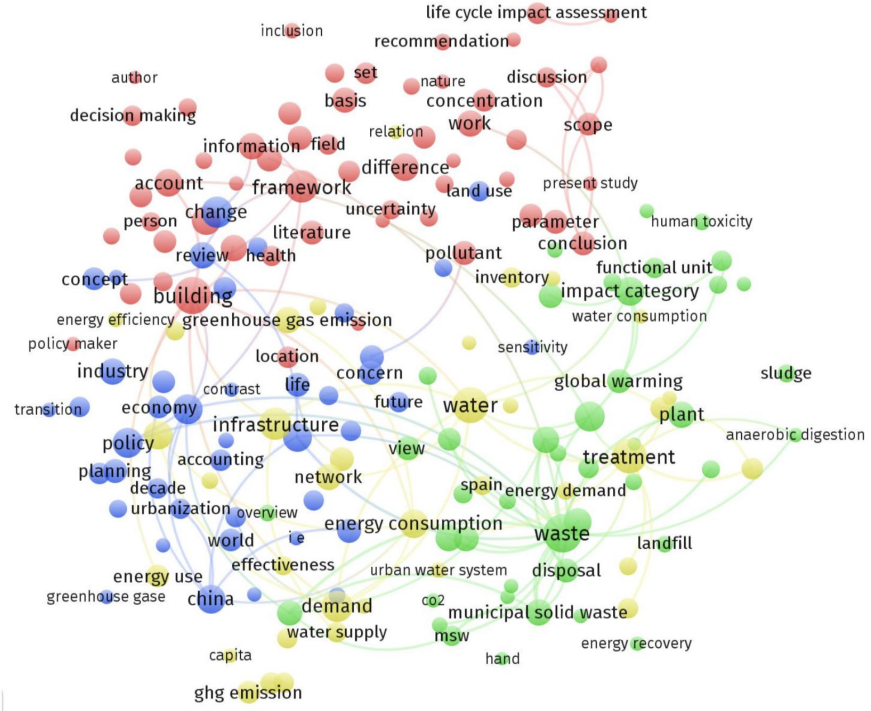

Figure 2. Term map representing the main research areas of LCA at the urban scale

with the results shown in figure 2. Four clusters of terms are illustrated in figure 2.

• Cluster 1 (blue): problems, urbanization/ planning, challenges/changes (left)

• Cluster 2 (red): building, information, framework (upper)

• Cluster 3 (green): waste, global warming, impact category (right)

• Cluster 4 (yellow): infrastructure, water/ treatment, greenhouse gas emissions (middle)

Cluster 4 is interwoven with clusters 1 and 3; in the term map, the closeness of the terms represents the intellectual connection and shared research interests and trends. Therefore, the author investigated the combination of clusters 1 and 4, with this focused research area redefined as ***urbanization and infrastructure planning***. Next, after combining clusters 1 and 3 together, one clearly defined focus area emerged: waste, water, and energy. Cluster 2, however, did not appear to have a clear leading term like the other clusters and is relatively separated from the other three clusters. Furthermore, its research terms appear to illustrate a high-scale challenge related to LCA at the urban scale, including framework and decision-making, building, and health. Accordingly, we gave this area of focus a more general description: *human factors and future uncertainty.*

Cluster One: Urbanization and Infrastructure Planning

A number of studies have examined the impact of residential and commercial density on energy use and life cycle costs within urban regions (Anderson et al. 2015). Low-density suburban neighborhoods were found to have higher energy use and GHG emissions per capita compared to a high-density urban core (Borg and Groenen 2005, Newman et al. 1989, Zhang et al. 2010). Increasing population density while maintaining low-rise building typology tends to reduce the total energy demands and associated greenhouse gas emissions per capita (Borg and Groenen 2005). Another important finding was that a reduction in house size had a positive impact on decreasing overall urban energy and material use. The composition of urban space impacts—mixed use versus single use—also demonstrates the impact of use on energy efficiency. The results found that households in urban centers had lower emissions than their suburban counterparts; however, the urban sprawl could neutralize all the benefits from urban development and redevelopment (Zhang et al. 2010, Conte and Monno 2012, Turconi et al. 2014).

Cluster Two: Waste, Water, And Energy

The second area is waste, water, and energy, which can be summarized as urban metabolism. An urban metabolism framework was developed with the aim to provide a foundational understanding of city resource uses and distribution (Naess 2009). Urban metabolism was originally developed by Wolman in 1965 as a methodology for measuring a city's overall energy, materials, water and nutrient inputs and outputs, and related processed and transformative energy and resources (Chester and Horvath 2012). Until now, the application of metabolism has been focused on energy consideration. Many studies on this have been conducted, including Ristimaki and team members who found that, in comparison to district heating, a ground source heat pump including 10% renewable energy was the most cost-effective method for an urban area with a 100-year life span (Newman and Kenworthy 2015). The shortcomings of the urban metabolism method lie in its lack of inclusion of upstream effects or a quantitative impact assessment regarding the local environment or human health. In a

recent report produced by a research team from the University of California, Berkeley, the research team assessed how the life cycle assessment method could beintegrated with urban metabolism to develop comprehensive energy and environmental inventories. Consequently, this approach could compensate the shortcomings of the traditional metabolism method.

Cluster Three: Human Factors and Future Uncertainty

The third area includes all topics relating to the complexity of urban issues, such as building-related health issues, decision-making, and associated information. Urban and built environments can be understood as complex social-ecological systems, where multiple related metabolisms interact at different scales (Berkes and Foke 1998), with the building representing just one scale in the holistic system. However, the cluster two (building) unlike others that are intertwined together, is isolated from infrastructure, planning, and energy consumption in other clusters. The disconnection of this cluster from others may be due to the emerging transdisciplinary research represented within the core of building industry: decision science, uncertainty theory, parametric modeling, and economy. The integration of multidisciplinary research is still in the infant stage, where including human factors as part of the decision-making process has been challenging due to uncertainty. Therefore, it will take some time before this research focus is mature enough to reach out to other areas. died energy (Jones and Kammen 2014).

4. DISCUSSION

In the current prevalent building-centric analysis approach, an individual building is regarded as a function unit, with individual building performance as the top priority. Analysis at the individual building scale treats the building as a stand-alone object, isolated from its context within the built environment (Anderson et al. 2015). This approach reflects the conception of the building as a consumer of resource and energy rather than as a producer of sustainability at different spatial scales (Turconi et al. 2014). Currently, life cycle energy consumption of buildings includes embodied, operational, transportation, construction, and demolishing energies. However, all of these are direct energies whereas several significant indirect energy types have not been included in the evaluation of building performance, which could represent a large missing portion. For instance, an office located in a dense urban space will result in much less energy being spent by occupants on commuting, due to widely available public transportation.

Another misleading concept, according to Pacheco's study, is the energy performance center: "A more energy-efficient building design does not necessarily coincide with more economical or more environmentally friendly designs" (Pacheco et al. 2012). The contribution of a building to sustainable development is assessed based on building performance (Kibert and Grosskopf 2012), with performance often quantified by energy performance and efficiency. Other indicators—such as indoor air quality, thermal comfort acoustic quality, visual comfort, and the occupants' well-being and satisfaction—are equally important to building energy performance (De Nooy et al. 2018, Rodríguez et al. 2013). Currently, some studies have tried to integrate those factors; however, a standardized procedure is still lacking.

The last knowledge gap involves the inclusion of temporal and human factors in LCA. Unlike other commercial products, a building has a much longer life span—about 50–75 years—and the use phase can have large environmental impacts, with multiple renovations and building upgrades related to building technology developments.

Variations within the use phase can sometimes be greater than the total impact of the materials, construction, and end-of-life phase (Burnett 2007), and the variations are often caused by the users' decisions, or human factors. The most current LCA studies of built environments use a static model that assumes the impact factor is constant over the time span. This could result in an inaccurate projection, as building materials and systems are constantly changing and improving. Instead, the measurement should have a dynamic framework, rather than a static one, to accommodate technology development.

Based on the findings from the literature review, the author can conclude that significant progress has been made over the past twenty years of life cycle studies and assessment at the building and urban scales, respectively. Very few studies have been conducted on integrated LCA for buildings within an urban context; such studies could reveal hidden factors and result in new findings.

CONCLUSION

The built environment assists societies in meeting basic needs for shelter and security. Throughout time, it has increasingly developed to provide greater scales of comfort and amenities, albeit with considerable environmental impacts (Chester and Horvath 2009). Accordingly, a comprehensive LCA framework that integrates different scales of the built environment could play a major role in promoting the reduction of related ecological impacts. Most current LCA studies are confined to their own scale and scope while lacking consideration of other related factors, such as population density, urban density, transportation accessibility, open space, and public parks. It is imperative to synergize LCA at the building and urban scales together, using an integrated framework. The potential to use an integrated framework in both urban planning and a building design context is a relatively new development. At the building scale, early adoption of an integrated framework could help designers, architects, and engineers find optimized solutions through quantitative analyses and evidence. At the urban scale, the planning process is a matter of organizing land use and optimizing resources, materials, and the energy flow within city boundaries. Therefore, a future integrated framework could be used in two ways: either as an analysis tool to aid the decision-making of government officials or as a design tool for urban planners. There is also a need for the planning and design community—specifically, architects, engineers, and planners—to work together as a synchronized unit to set up work for a higher level of LCA integration in the built environment (Chester and Horvath 2012).

This research project identifies primary LCA research activities at the building and urban scales, followed by an explanation of the main research areas of focus and an outline of the knowledge gaps. Findings from this research project include other important environmental factors and also provide a foundation for further studies of an integrated framework incorporating LCA from different scales. There are limitations in this research, as LCA was divided into two macro-scales: building and urban. Significant differences exist between different micro-scale urban contexts—such as city, neighborhood, and district—thus there are specific considerations related to each individual scale.

PAPER #6.03

COMMUNITY PRESERVATION OF DISTRICTS: THE *BROWNSTONERS*. THE CASE OF BEDFORD-STUYVESANT

Ana García Sánchez[a]
[a] Universitat Politècnica de València, Valencia, Spain

ABSTRACT

The preservationist movement started in New York City in the mid 1960s, as a reaction to the losses of a series of historically significant buildings for the city. In response, the Mayor Robert F. Wagner, Jr. enacted the Landmarks Law in 1965, which laid the foundations for the creation of the Landmarks Preservation Commission, main municipal agency in charge of safeguarding built heritage in New York City.
In these same years, a group of intellectuals created an association to protect the brownstones, a housing typology characteristic of New York City in the 19th century. These activists called themselves brownstoners, and their mission was to fight against the massive demolitions of this type of dwelling and their subsequent replacement by modern apartment buildings.
In New York City, on top of the philanthropic contributions coming from the private sector (something typical of American culture), it is paramount the work of local associations and the same citizens when it comes to deciding which buildings and collections of them are liable to be granted landmark or historic district status.
An example of a historically deteriorated neighborhood at the heart of Brooklyn was taken, Bedford-Stuyvesant, in order to prove how community efforts can have a determining effect on the Commission's decision to have a collection of buildings designated as a historic district.
This system of heritage management that gives so much importance to community support may be a valuable contribution to the model that currently prevails in our country.

KEYWORDS

Heritage; preservation; brownstones; bedford-dtuyvesant; New York City.

INTRODUCTION: BUILT HERITAGE PRESERVATION IN NEW YORK

In the United States, public awareness about the importance of protecting historic buildings is something relatively recent. The New York Landmarks Preservation Commission (LPC) was created in 1965 when the Mayor Robert F. Wagner signed some legislation in response to the losses of several historically significant buildings.

Figure 1. Pennsylvania Station, 1911. Source: (Library of Congress, Prints and Photographs division, Detroit Publishing Company Collection 1910)

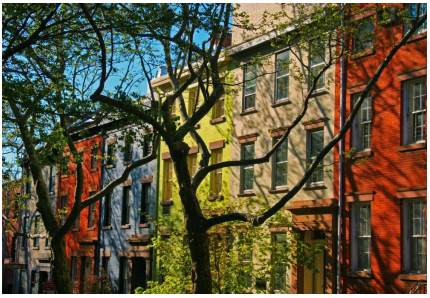

Figure 2. Row houses in the Brooklyn Heights historic district, 2012

The most infamous and controversial of these losses was Pennsylvania Station in 1963, when the building designed in 1911 by the renowned architectural firm of McKim, Mead & White (Fig. 1) was demolished to make way for the multipurpose venue Madison Square Garden. Some years later, there was another milestone, also related to a train station, Grand Central Terminal. In this case, the Commission rejected the construction of a 55-story tower above this station. The case was taken before the U.S. Supreme Court, which decided to keep the historic building as it was, victory in favor of the preservationists that strengthened the Landmarks Law and validated the preservation movement across the country. As well as protecting individual structures, this legislation also designates historic districts, interior landmarks and scenic landmarks. It is worth mentioning that, on the other side of the ocean, legal protection was granted at the same time to individual landmarks and to historic ensembles. Thus, the first historic district that was approved in New York City was Brooklyn Heights (Fig. 2) in 1965, the same year that the Commission was founded and the Law was enacted, unanimously and with great support from neighbor associations and homeowners. It is interesting how this designation was made just a year after in Europe started the concern about preserving historic centers, since the publication of the Venice Charter in 1964, where for the first time "modest works" are mentioned (Icomos 1964, 1). A consideration to consider regarding historic districts protection (or any other property subject to protection) in New York is related to the designation process. Naturally, proposals may be initiated by the same Commission members, through research they carry out regularly, with surveys which are also inventories of the city's significant buildings. However, it is noteworthy is that any member of the public can submit a Request for Evaluation (RFE). In order for the Commission to consider these requests, it is necessary that enough support from residents and neighbor associations is shown (Historic District Council 2018), as we will confirm on the example described below. Besides the governmental organizations, it is essential the work of other non-profit associations that cooperate with the advocacy of New York's built heritage, for instance, the New York Landmarks Conservancy and the Historic Districts Council (HDC), both of them having been started in the early 70s, soon after the Landmarks Law was passed.

1. THE *BROWNSTONERS*

Back in the 60s, while many white families fled the hustle and bustle of the city looking for the suburbs' peace and African American and Puerto Rican immigrants crowded in the housing projects (public housing developments), a group of middle-class educated young people (Osman 2011, 8; Schuman 1973) settled down in a neglected neighborhood in Brooklyn, focused on preserving the urban typology of the 19th century par excellence, row houses, more commonly known as brownstones.[1]

These houses were suffering a massive demolition because of their advanced state of decline, due to having been abandoned a few decades before or occupied by more people

[1] *Brownstone* is a kind of sandstone which the façades of most houses at the time were built with and, by extension, in New York any row house built around this time is termed a brownstone, be it this material or other, such as limestone or brick (Lockwood 1972, xiii).

than they should, after their subdivision into several apartments, as well as because of their location in troubled neighborhoods, with a population comprised mainly of Latin and African American immigrants that had moved to New York looking for better job opportunities (Lockwood 1972; Osman 2011; Schuman 1973).

These activists, who named themselves brownstoners, founded the Brownstone Revival Committee and gave rise to the movement known as Brownstone Revival, which soon expanded to other areas of Brooklyn[2]. They started to restore some of these houses, in an attempt to give them back their original magnificence (Osman 2011, 5). The neighborhoods that they occupied were called "Brownstone Brooklyn" (Fig. 3) and their names were coined during these years. What they were searching was a sense of belonging to a community, rather than the anonymity of the suburbs. As Osman (2011, 5-6) states:

> Brownstoning was a cultural revolt against "sameness", conformity and bureaucracy. In a city that was increasingly technocratic, Boerum Hill[3] was a "real neighborhood," a vestige of an "authentic community" lost in a modernizing society.

Figure 3. Location of the brownstone neighborhoods in Brooklyn.

In its early years, however, the organization focused on fighting red-lining, a process where banks denied loans to immigrants in these neighborhoods. However, their results were not immediate, as an article on the *New York Times* from 1976 showed. In these years also operated a sister organization, the Brooklyn Brownstone Conference, which proposed the Brownstone Savings & Loan, a new savings and loan association that provided money for buying and renovating brownstones.

In 1974 the Brownstone Revival Committee issued a publication, *Home-buyer's guide to New York City Brownstone neighborhoods*, destined to potential brownstone buyers, where they described a series of neighborhoods where these houses could be found, and offered their price and state of preservation. In addition, they started to promote their designation as historic districts. Their preservation efforts led to these neighborhoods' social and economic regeneration, which went hand in hand with a rise in property values (Osman 2011; Schuman 1973).

Another line of work of the Brownstone Revival Committee was education, which proved to be very popular, according to a 1973 *The New York Times* article. In order to help the brownstone enthusiasts renovate their new houses appropriately, the Brooklyn Brownstone Conference also sponsored the Brooklyn Brownstone Fair for several years starting in 1972, with an array of experts who could offer practical advice, among which was the Brownstone Revival Committee, along with representatives from all the brownstone neighborhoods.

This organization is still operating today, under the name of *Brownstone Revival Coalition*, offering guided tours, seminars and newsletters. In addition, they keep a list of craftsmen and preservation specialists that these houses' homeowners can turn to when they have to carry out restoration work on them.

[2] The great brownstone revival is continuing throughout Brooklyn, thanks in part to the enthusiastic proselytizing of "pioneer" brownstoners who began to reclaim blighted neighborhoods in the early nineteen sixties (Schuman 1973)
[3] Boerum Hill is another neighborhood in downtown Brooklyn with an abundance of brownstones.

2. CASE STUDY: BEDFORD-STUYVESANT

Bedford Stuyvesant's (Fig. 4) urban development started in the mid-19th century, during the American Civil War, when the Dutch farmers that had settled there during the 17th century sold their lands to speculative builders and real estate developers, who turned the existing rural community into an urban residential area of brownstones for upper and middle classes. In the 1860s and the 1870s an increasing number of merchants who worked in Manhattan, mainly of German and Dutch origin, established residence in Bedford (Echanove 2003, 3), as well as families coming from New England. Thus, Bedford became a very attractive and sought-after neighborhood, and proof of that is the refined architecture of the houses that mushroomed all around the empty lots, replacing most of the freestanding frame houses from the colonial era (Fried 1969; Lockwood 1972, 251). The most intense construction period was between 1895 and 1900. During this first stage, some wealthy African Americans also bought houses in the area. Over these years, it was a well-to-do neighborhood. After the First World War, and particularly after the Great Depression, the demographics started to change. The upper and middle class fled the area, moving to the suburbs, causing thus a drop in property value that was taken advantage of by the immigrant working class, comprised of a variety of ethnic groups (Jews, West Indians, Irish, Italians), who worked at the Brooklyn Navy Yard, near the Brooklyn Bridge. As Echanove mentions (2003, 3) when the subway line that connected the neighborhood with uptown Manhattan was built in 1936 along Fulton Street, many inhabitants from a crowded Harlem migrated to central Brooklyn, which offered more jobs and better housing. After World War II, the black population grew to dominate the neighborhood completely; by 1940, sixty-five thousand blacks lived here (Morrone 2001, 252). These demographic shifts, however, maintained intact the architectural character of the neighborhood (Fig. 5):

> while the brownstone houses of Bedford were solidly built and long lasting the community itself was to be temporary, transformed in a few short years by the ceaseless forces of urban change (Ment and Donovan 1980 cited in Echanove 2003, 3)

This was, however, only exteriorly, as in the 1930s and 40s many brownstones were subdivided into multiple dwelling and rooming houses (Morrone 2001, 251), as it has been seen on the previous section that happened in many other areas of Brownstone Brooklyn.

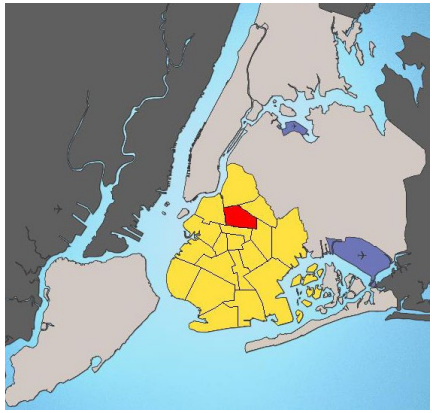

Figure 4. Location of the Bedford-Stuyvesant district within the borough of Brooklyn. Source: (Schorzman and JacobS 2009).

Figure 5. Halsey Street and Nostrand Avenue. Source: (Irma and Paul Milstein Division of United States History, Local History and Genealogy, The New York Public Library 1941)

The neighborhood fell into decline during the central decades of the 20th century, partly because of the tension caused by the racial riots and the crack epidemic that took place during these years at the New York areas inhabited mostly by black people, as well as redlining from the banking institutions. As Morrone (2001, 252) states "In the 1960s, Bedford-Stuyvesant became synonymous with the "urban crisis" in America"[4]. As property value kept dropping, black people came to Bedford-Stuyvesant because they were not able to be anywhere else.

In addition, during these years the construction of housing projects for low and moderate-income residents on the northern part of the neighborhood gave it a bad reputation. Another problem were abandoned residential properties. As housing deteriorated to slum conditions, the community turned gradually into "one of the nation's worst urban ghettos" (Rejnis 1974).

In 1967, Senator Robert F. Kennedy decided to tackle the problems that these neighborhoods faced, marked by poverty and left to themselves by the public authorities, and planted the seeds for what would become the Bedford-Stuyvesant Restoration Corporation, the first Community Development Corporation[4] in the country, after touring the dilapidated area.

This organization was born with the mission of creating job positions, renovating the existing housing and building new, affordable houses. During its first years it was moderately successful: after four years, the Corporation had improved the physical appearance of 55 blocks, renovated the exteriors of 2,230 brownstones, erected a 52-unit apartment house and rehabilitated 34 others (Emerson 1972). This work was done entirely by unemployed community residents who were given training by the Corporation. The President of the Corporation stated in 1972:

> The impact of young guys off the streets, learning a skill and seeing a job finished and homeowners seeing what they can do has an energizing effect. We are further along as a community now.

Senator Kennedy even invited the prominent architect I.M. Pei to consult on the physical planning needs of the area (Morrone 2001, 252). The result was the execution of an urban enhancement project on two blocks within the neighborhood, which, according to I.M. Pei's office, provided the variety of focal points that the area had been lacking (Fig. 6).

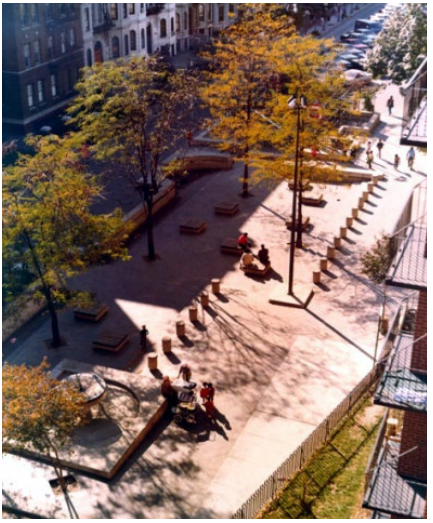

Figure 6. I.M. Pei's superblocks in Bedford-Stuyvesant. Source: (Pei, Cobb, Freed, and Partners 1969)

At the Brooklyn Historical Society there was a collection of magazines that this association published between the years 1975 and 1981, where they offered some interesting data and statistics about the neighborhood and the regeneration work of the Corporation in those difficult years. They stated that

[4] Community Development Corporation are not-for-profit organizations that provide programs, services and other activities that promote and support community development in struggling neighborhoods organizations are often associated with the development of affordable housing.

Bedford-Stuyvesant had traditionally been a stable community, with half of its residential buildings being owner-occupied. Finally, in 1981 there was news of restoration projects of old, abandoned buildings with public funding, which were destined to social housing.
But all these projects would not have been materialized without the people of Bedford-Stuyvesant. The owner of a house at one of the blocks object of I.M. Pei's project stated that

> now it's all nice again, and it's just because the people on the street wanted to make it that way (Borders 1969)

The "brownstoning" phenomenon also arrived in Bedford-Stuyvesant in the 1970s, with people who had grown in the neighborhood but had left for college. Instead of heading to the suburbs, they moved back and started renovating brownstones, joining block associations[5] and getting involved in other aspects of community life (Landmarks Preservation Commission 2015b, Rejnis 1974). The president of one of these associations claimed that "What Bedford-Stuyvesant needs is more of its people to care about it" (Fried 1969).
In 1978 "a small group of friends and neighbors who wanted to make a contribution to their great community" founded the "Brownstoners of Bedford-Stuyvesant", a non for profit organization dedicated to the preservation, revitalization and enhancement of the neighborhood. They tried to change the media's concept of the community, sparkling new pride in the neighbors who still lived there and encouraging many African Americans to come back to the properties that their parents and grandparents coming from the South and the Caribbean, had worked hard to acquire. It is still operating today, being one of its committees dedicated to promoting affordable housing and planning the annual house tours.
Recently a new wave of immigrants, from a variety of ethnic origins, has arrived in the neighborhood, having achieved its revitalization, by renovating and occupying properties which had been previously abandoned. The main reasons behind the growth and the charm of the neighborhood are its strong sense of community as well as its abundant and handsome houses, being the area of Brooklyn with the highest concentration of this typology. Signer (2012) speaks of these new arrivals as a second wave of brownstoners.
Echanove (2003, 3) suggests that the preservation works undertaken by community and governmental organizations, such as the Bedford-Stuyvesant Restoration Corporation, have been instrumental in uplifting the neighborhood. The Landmarks Preservation Commission (2013, 3) agrees: "this effort (…) has brought renewed stability the historic neighborhood".
However, the main disadvantage of the neighborhood's development, from the point of view of historic preservation, is the renovation of its housing stock by speculators, in the form of "luxury" developments, progressively removing the elegant row houses that made it famous (Vandam 2009). Here is where designations of historic districts come into play.

Figure 7. Row of brownstones within the Stuyvesant Heights historic district. Source: (Landmarks Preservation Commission 2013)

[5] Block Associations are groups of residents who decide to collaborate to strengthen a block or area, beautifying neighborhoods or advocating for better crime prevention. Their organization and governance comes in a variety of formulas. Nowadays, Bedford-Stuyvesant has the biggest concentration of block associations in the city (Schubach 2016). In 1969, it already had 100 block associations that "are striving, with varying degrees of effectiveness, to foster community improvement and spirit" (Fried 1969).

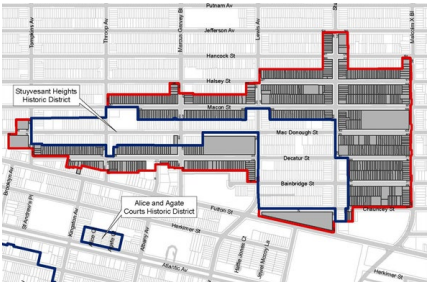

Figure 8. In red, boundaries of the expanded Stuyvesant Heights historic district. In blue, boundaries of preexisting historic districts. Source: (Landmarks Preservation Commission 2013)

In 1971 the Stuyvesant Heights historic district was designated, being expanded in 2013 (Fig. 7 and 8), after public hearings having taken place in 1993 and 2011. On the press release that followed the designation, Commission Chairman Robert B. Tierney made a statement highlighting the importance of community support (Landmarks Preservation Commission 2013, 2):

> We finally crossed the finish line today, thanks to a great deal of work by the residents, homeowners and leaders of this community. We look forward to our continued partnership with them to protect the extraordinary streetscapes of their neighborhood, one of the most renowned in New York City

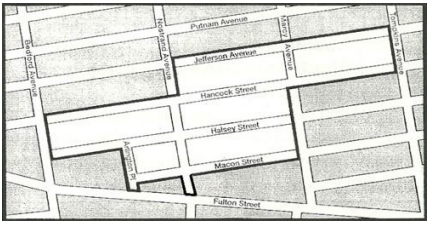

Figure 9. Boundaries of Bedford historic district before the official survey. Source: (Brownstoner 2010)

In 2010 started the process of protecting another historic district in the southwest section of Bedford-Stuyvesant, when the Bedford District Block Associations (BDBA) submitted a RFE to the Commission (Fig. 9) and started collecting signatures in support of the designation (Brownstoner 2010). They arranged meetings as well in order to inform the neighbors about what it would mean to have their house protected.

Figure 10. Rows of houses at the Bedford historic district proposal. Source: (Landmarks Preservation Commission 2013)

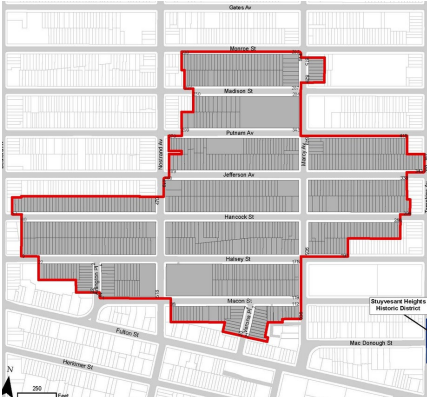

Figure 11. Final boundaries of the Bedford historic district. Source: (Landmarks Preservation Commission 2015)

Finally, the historic district was calendared on May 12, 2012, and the public hearing was scheduled on January 15, 2013. On the hearing, there was a presentation on the district, including photographs of relevant rows of houses (Fig. 10). The spokesperson for the New York Landmarks Conservancy also testified at the public hearing, stating that:

> The Conservancy is pleased to have that community as partners in preservation (…) This designation will only spur more applications and more improvements. We (…) look forward to speaking on the other Bed Stuy areas, including Stuyvesant East and Stuyvesant North, as well as several others

At the time, there were opposed positions (Budin 2013; Dunlap 2013; Landmarks Preservation Commission 2015a, 1; The New York Landmarks Conservancy 2013), and the Commission's vote was postponed[6]. It was not until December 8, 2015 that the Commission unanimously approved the designation of Bedford historic district (Fig.11).

As it has been already argued, the work of community associations is crucial when it comes to the Commission considering approval of a Historic District proposal[7]. In 2013 there were several associations that promoted the preservation of Bedford-Stuyvesant, whose work was decisive in order to get the positive vote from the Commission: the B*edford Stuyvesant Society for Historic Preservation, the Bedford Corners Historic District Joint Block Association and the Stuyvesant East Preservation Action League*.[8] The first one gathered information about the different historic districts that have been proposed in the area of Bedford-Stuyvesant and worked closely with the HDC to promote Bed-Stuy's historic district (Frishberg 2015). As for the second, it was basically a portal that answers the questions of the owners and residents in the Bedford area regarding its designation as a historic district and what this would entail, declaring itself in favor of its preservation, and offering the chance of signing a petition supporting the designation. There was also a section with news related to the historic district and its designation. The third one had more or less the same mission, but focused on the Stuyvesant East area.

3. THE SPANISH MODEL

In order to ascertain what the New York model of heritage management can offer to our system, we need to provide some information about how our model works. According to the Spanish Historic Heritage Law (Cortes Generales 1985, 10) and the Valencian Cultural Heritage Law (Cortes Valencianas 1998, 22), the designation of a landmark can be initiated by the administration or by citizens. The process includes a stage where the proposal is publicly exposed and a public hearing for the affected city councils is held. Then, article 5.4 of the Valencian Cultural Heritage Law (Cortes Valencianas 1998, 14) states:

> The Valencian Government will promote a collaborative framework with volunteering associations for the preservation and dissemination of the Valencian Cultural Heritage.

[6] According to the LPC (2015a), thirty people spoke in favor of designation, three people testified in opposition and three people questioned whether the designation process had provided enough community notification. The LPC received 356 form letters and emails in support of the historic district, and 220 letters stating that they wanted additional information about the process

[7] According to a 2011 news article "LPC didn't see enough community consensus to convince them that the Bed-Stuy residents wanted the designation (…) without community support, the LPC is not going to do this. If they don't see community support, they walk away (…) We've been on their agenda since 1993. They're just waiting to see the neighborhood support (Morris and Staff 2011)". Also, in 2011, Spellen stated after an informative meeting with the LPC that "Landmarks was very pleased by the turnout and positive interest of the majority of the crowd, an important part of their decision to landmark any area"

[8] The information about these three organizations was retrieved from their websites in 2013, but they are no longer operating, hence why they are not included on the reference list.

This is as far as Spanish law goes in relation to the role of non-governmental organizations and citizens on landmarks designation and preservation.

CONCLUSION

Having seen this, it can be asserted that the model of heritage management that prevails in New York presents very interesting contributions that could be adopted by the Spanish system, such as the necessity of community involvement when it comes to protecting their built heritage. The case of Bedford-Stuyvesant is an example of how people of the community can help regenerate and preserve a historic neighborhood, be it by renovating its façades or advocating the designation of the district. However, public awareness of the importance of safeguarding historic buildings and districts would not be what it is today in this city was not for the work of the brownstoners and other activists that set out to reclaim those houses and neighborhoods that no one valued at the time.

PAPER #6.04

DEFROSTED ARCHITECTURE: DEBUSSY'S *CATHÉDRALE ENGLOUTIE* CASE STUDY

José L. Baró Zarzo[a], Pedro Verdejo Gimeno[a], Gracia López Patiño[a], Verónica Llopis Pulido[a]
[a] Universitat Politècnica de València, Valencia, Spain

ABSTRACT

Music is liquid architecture; architecture is frozen music said once Goethe quoting Novalis; *music is mobile architecture*, declared Xenakis, while according to Pallasmaa, *architecture is the art of petrified silence*. All these expressions deepen in a same idea, the material consistency of matter in front of the ethereal volatility of sound; but they also suggest another think: the interchangeability of their states of matter, solid from liquid, water from ice. Is it possible? To look into such a slippery business, we'll move closer to the programme music, that which, as opposed to absolute music, attempts to represent extra-musical contents (poems, images, descriptions…). In our case, we'd rather a piece based on an architectural program. Debussy composed the famous prelude for solo piano *La Cathédrale Engloutie* (The Sunken Cathedral) by 1910, inspired on an ancient legend: in the coats of Brittany, the mythical city of Ys had immersed into the sea and every clear morning the cathedral emerges from water and sinks back again.
This paper tries to discover the musical resources employed by Debussy to evoke specific architectural images, like Impressionist painters also did. For this purpose, we'll turn to the analytical study of the main musical components under the perspective of Architecture.

KEYWORDS

Music and architecture; impressionism in music; programme music; préludes for solo piano; city of Ys.

INTRODUCTION

It should be noted that the following text is not intended to give an absolute depiction of the extramusical content of Debussy's Prelude. Quite the opposite, only a possible interpretation is here presented.

1. CONTEXT

1.1. The Preludes for piano (1909-1910) by Claude Debussy (1862-1918)

The poetic sensitivity of Claude Debussy, the light and color that emerge from his music, have earned him the qualifier of "sound painter":

> Judging by his works and by their titles, he is a painter and this is what he wants to be; he calls his compositions pictures, sketches, engravings, arabesques, masks, black and white studies. There is no doubt that for him it is a pleasure to paint in music.[1]

The personality of Debbussy stands out for his bohemian and rebellious character, little given to follow the established. His music was influenced by the nationalist Russian composers (Mussorgsky, Rimsky-Korsakov...), the Impressionist painters (Monet...) and, above all, by the French symbolist poets (Mallarmé, Rimbaud, Verlaine...). In front of the grandiloquence of the Sublime, embodied by Richard Wagner, whose figure could not go unnoticed at the time, Debussy's musical choice was focused towards the delicacy of the Beautiful. Facing

[1] Quotation of René Peter, Debussy's close friend. Quoted in: Thompson (1967). *Debussy: Man and Artis*t. New York: Dover, p. 19.

the shape and structure of German music, he bets on color and texture.

It was from the 1890s when Debussy abandoned abstract music in favor of a more programmatic conception (Morgan 1994: 59). The composer chooses picturesque scenes that boost the recreation of suggestive atmospheres in search of the pleasure of listening, far away from the tears provoked by the expressionist music of Schoenberg and Webern.

In his mature period, Debussy composed two volumes of preludes for solo piano, containing short pieces of varied subject matter. They are works of independent character, in the line marked by Frédéric Chopin in his Op. 28 (Llácer 1980: 127), that is, without subordination to other subsequent piece of greater extension. The total number of pieces is 24, the same as each of the volumes of Johann Sebastian Bach's *The Well-tempered clavier* and the aforementioned album by Chopin. However, unlike these, Debussy does not follow a predetermined pattern that justifies the number and order of the pieces, which is why concert performances are not always integral and do not always follow the original numbering correlation. The first volume of preludes[2] was composed between December 1909 and January 1910 and, that same year, they were edited and premiered.[3]

It is a music more evocative than descriptive. In fact, the title of each prelude does not appear at the beginning of each piece, but just at the end: it appears in brackets and after suspension points, as if wanting to leave the performer to transmit his own impressions, without conditioning him by those of the composer. However, the extra-musical reference of Prelude n. 10, *La Cathédrale engloutie*, is very specific. But let's know first where it is inspired from.

1.2. The city of Ys

The legend of city of Ys is based on historical facts about King Gradlon, in the area of Brittany, near Quimper, around the 6th century of the Christian era. From then on, the popular tradition has been fattening the myth of the submerged city. Ys was a town of Celtic origin, built below the sea level, so it was surrounded by dikes to contain the onslaughts at high tide. A single gate allowed ships to pass through during the low tide, the key to which was jealously guarded by Gradlon.

One night, while the king was asleep, Princess Dahut, his daughter, wanting to please his

[3] First edition in Paris, by Durand et Cie., April 1910. The first performance or Preludes n. 1, 2, 10 y 11 took place at the *Société musicale indépendante* in Paris, played by own Debussy. The first comprehensive audition of the 12 preludes was on 3 May 1911, at the Pleyel Hall in Paris, performed by pianist Jane Mortier.

lover's madness, stole the key and handed it to him. The lover ran to open the door and the city began to flood, disappearing soon after under the waters. The king managed to reach his horse on dry land riding on the waves, but during the scape the princess fell off the horse (Fig. 2), and then she sank and transformed into a mermaid.

The legend tells that in calm days one can hear the chime of bells and the singing of monks of the ancient cathedral from the depths. This and other popular Breton songs were rescued from oblivion by Théodore Hersart de la Villemarqué in 1839, in a book of great reception (Fig. 1), from which some texts would be adopted and adapted for several artistic manifestations, including Debussy's famous prelude.

2. *LA CATHÉDRALE ENGLOUTIE:* FORM AND STRUCTURE

Now entering to spell out the musical contents, we can first state that this prelude consists of a short (89 bars, about 6 minutes long), slow ("profondément calme"), soft (mostly between *p* and *pp*) and very tied piece. Although it is theoretically in C major and C# minor, the fact is that there is no clear tonal center because of the chromatism, the use of Gregorian modes, the sequence of parallel octaves and fifths, the pentatonic and whole tone scales, and the arrangement of triads with no harmonic function. The desire for freedom affects also the rhythm. The initial equivalence of two time signatures implies an ambiguity in the pulse, opting for duple compound meter in some segments (6/4, e.g. bars 16-21), and triple simple meter in others (3/2, e.g. bars 28-46).

It cannot be said that the musical fabric is woven by themes or melodies in the traditional sense, but rather by "short motivic cells that are variations of other interconnected to one another" (Morgan 1994: 60). Among the motivic units there is a very frequented cell, formed by notes D-E-B (bars 1, 3, 5, 14, 15, 84, 85), taken both ascending and descending. But just because the genesis of the work is not thematic it does not mean that there are no themes. We will quote two, formed in turn by motivic material: the melody of bars 7-13, which is later repeated in measures 47-51, and the theme formed by parallel chords in 28-38.

Figure 2. Évariste Vital Luminais: La Fuite de Gradlon (1884). Source: Musée des Beaux-Arts, Quimper.

2.1. Program

As we said, the extramusical reference of *La Cathédrale engloutie* is very specific. Some of the nuances of expression contained in the score refer directly to phenomena compatible with the mythical legend, such as the misty atmosphere that is ordered in measure 1 ("dans une brume doucement sonore") or in bar 16 ("peu à peu sortant de la brume").

In the course of the piece, the cathedral seems to emerge from the sun-bathed waters and then to return to depths, while ringing bells, religious chants and organ chords are heard. It is possible to imagine this tour from the very structure of the work.

2.2. Structure

From the get-go, the prelude comprises three sections divided by corresponding key signatures (Tab. 1), resulting in an A-B-A' scheme, where the last part includes fragment variations of the first. The initial section (bars 1-46) is in C major, the central (47-71) in C# minor, and the last one (72-89) in C major again. However, this organization is far from the rigid scheme typical of classicism, since the material is freely reworked.

In turn, each section contains several variable extension segments, which are underlined -although not always- by indications of *tempo*.

2.3. Section A (bars 1-46)

Within the first section, the longest of the three, subsection A1 (bars 1-15) represents the haze on the swell and the depths with the submerged cathedral; subsection A2 (16-27) evokes the gradual emersion of the temple; while segment 3 (28-46) already shows the majestic building clearly raised on the waters.

In turn, each of these passages could be broken down into smaller segments. And so, in the first part, the succession of ascending chords in pentatonic scale (D-E-G-A-B) over a pedal note in the first bars (1-6) is taken up again in ascending and descending movement at the end of this same subsection (14-15), allowing the clerics' singing be heard, still underwater, in the central bars (7-13) with the indication "doux et fluide", a theme that will reappear more clearly in section B.

The following subsection (16-27) comprises a first part in which the series of ascending and descending chords continue progressively increasing their intensity (16-21), in the presence of an ever-raising temple, to conclude with a transition passage composed of descending octaves in diatonic and pentatonic scales (22-27) that prepares the entry to the next subsection.

The beginning of the last excerpt goes along with the indication "sonore sans dureté". It starts with a very intense first part (28-38) that represents the sound of the organ rhythmically accompanied by bell taps (pedal note). It is the moment of greatest splendour, in front of the imposing volume of a cathedral outlined with grazing lighting. Tonality remains stable in C major, with homophonic texture based on parallel chords. After this passage, and before entering the next section, the musical discourse goes through two brief episodes: the first of transition (bars 39-41), and the second of returning to calm, where the soft chime of bell becomes diluted (42-46).

2.4. Section B (bars 47-71)

The second section begins with the same melody heard in 7-13, but two octaves lower (measures 47-51), and continues in a high-pitched position, intensifying the listening up to bar 61. The end of this passage is

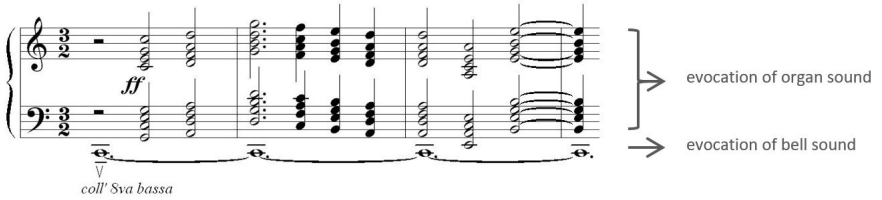

Figure 3. Claude Debussy: La Cathédrale engloutie, bars 28-31. Source: Petrucci Music Library.

reinforced by appoggiaturas in the left hand (59 and 61).
Suddenly, dynamics fades and evolves descending through a bridge of dominant seventh chords (bars 62-65: D#7-C#7-B7-A7-C#7-G#7), closing with a double cadence. The section ends with a new transitional episode (66-71).

2.5. Section A' (bars 72-89)

In the last section, the shortest one, the motivic development of measures 28-38 is repeated, but with significant differences: dynamics goes from *ff* to *pp*; the pedal note is transformed into an unfolded chord, whose *ostinato* oscillation recovers the soft swell and sun reflections; and, in addition, right hand chords descend an octave, all with the intention of generating "comme un écho de la phrase entendue précédemment" (72-83), evoking the progressive return to immersion and the reappearance of the misty atmosphere on the waves.
At the end of the piece, the ascending chords of the first bars are taken up again (84-85), with the indication "dans la sonorité du début". The cathedral has been completely submerged and now only the mist can be perceived. This passage is solved in the final cadence, where the sound is slowly extinguished with chords that extend to the entire keyboard range (measures 86-89).

3. *LA CATHÉDRALE ENGLOUTIE:* EVOCATIONS

Once analysed the structure of the piece, we'll interpret what Debussy might evoke with his music and how he carried it out.

3.1. Remote times

At the time to move the imagined scene into the past, Debussy uses at least two resources.
On the one hand, he introduces the *organum*, or movement by chords with parallel octaves and fifths, which refers to the origins of polyphony in 11th and 12th centuries (*Ars Antiqua*). This movement was banned in Western music during the Renaissance precisely in order to distance itself from what was considered as outdated.
On the other hand, the composer resorts to different Gregorian modes, transcending the limitation to the major and minor scales of the tonal system. The use of Lydian (T-T-T-S-T-T-S)[4] and Æolian (T-S-T-T-S-T-T) modes will be discussed later. Doric mode (T-S-T-T-T-S-T) is present in bars 23 and 24 over D.

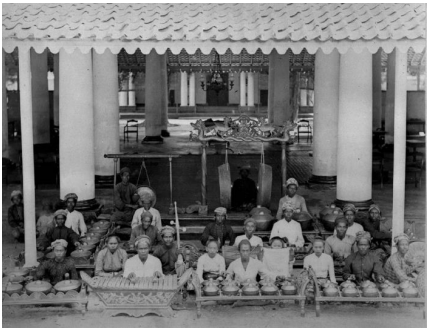

Figure 4. Gamelan orchestra in Java, late 19th century. Source: Tropenmuseum, Amsterdam.

[4] T: tone; S: semitone or half tone.

3.2. Exoticism

Although at first the pentatonic scale connects with the sound of Eastern music -in the case of Debussy, the connections would lead to Javanese gamelan, which he met at the Paris Universal Exhibition of 1889[5]- (Fig. 4), it is likely that the search for the exotic is mixed with references to the distant in time and the aura of suspense that surrounds the myth. Among other passages, there are pentatonic sequences in bars 16-18 (B C# D# F# G#) and following (19-21: E_b F G B_b C; 22-23: G A C D F) (Bruhn 1997: 42-44).

3.3. Religious content

The legend of Ys is imbued with ethical-religious connotations around the idea of sin, incarnated in Princess Dahut, as a result of which the destruction of the city would have been derived as divine punishment, as Sodom and Gomorrah were in their time. Also involved in the story was Saint Winwaloe, founder and abbot of the first monastery established in Armorica region, who had prophesied about what would eventually happen.

At a time when the Christian tradition is still present in French culture, Debussy resorts to sound references linked to the Christian liturgy to evoke this specific atmosphere: organ chords, monodic singing, and bell ringing.

The sound of **organ** appears in all its sumptuousness in bars 28-38 (Fig. 3), with a dense, sharp, homophonic, and rhythmic texture, without being polluted by the existence of other effects except for the bass touches of pedal. The movement by parallel fifths and octaves has already been mentioned.

As for **singing**, the arrangement of a simple melodic line with no doublings comes to evoke the monody of Gregorian chant, performed by male voices. This tune is half-heard fleetingly from the depths in measures 7 and 13, and then plainly with the cathedral emerged (47-51); the first in Lydian mode on E and, the second in Æolian or minor mode over G# (Bruhn 1997: 42-44).

Finally, the ringing of **bells**, understood among the Christian tradition as a sign to summon the faithful, is evoked through the iteration of long-lasting pedal notes in deep range.

3.4. Architecture

In bars 16 and 17, the symmetrical up-down movement (F#-G#-D#-G#-F#) of the right-hand chords represents almost literally the outline of some towers, still under water, but already visually noticed. The melodic drawing with a 5th jump in the middle suggests a pointed top, perhaps a steeple or a spire. At bar 18, symmetry becomes imperfect (F#-G#-D#-F#-G#), perhaps by glimpsing the connection of the towers to the central nave (Fig. 5).

Figure 5. Claude Debussy: La Cathédrale engloutie, bars 16-19. In red the ascending and descending movement of the chords that suggests the vision of two towers. Source: Petrucci Music Library.

[5] The sonority of Thai gamelans has influenced many composers, such as Debussy, Satie, or John Cage and their *prepared piano*.

The magnificence of the building is shown in subsection A3 (bars 28-40), by means of resources such as the key of C major, very clear in 28-32; the homophonic texture formed by parallel diatonic triads with the counterpoint of a bell; the intense dynamics (*ff*); and the simple motivic development, both melodic and rhythmically. These tools may also insinuate the presence of consistent and imposing materials, such as a stone ashlar fabric.
Over this play of solemn representation, another capricious and delicate game is superimposed: the arabesque. In bars 19 to 21, Debussy introduces a recurring ornament consisting of groups of three or four descending fast notes (even reinforced by an *acciaccatura* in bar 20), which just appear in full ascent of the temple to the water surface. It could be interpreted in a vague way with the progressive visualization of the decorative apparatus that usually accompanies the architecture of great cathedrals (traceries, moldings, foliage…). The melodic material however does not seem to refer to a specific stylistic affiliation beyond providing a simple exotic touch.

3.5. Emersion - immersion

The dynamic intensification and the progression to higher-pitched tessituras suggest the rising ascension of the temple to surface (Bruhn 1997: 42-44). This phenomenon occurs from bar 18 (*p*), passing through 22-24 (*f*), 25 (*più f*) and 27 (*sff*), until measure 28 (*ff*). The opposite process implies consequently the descent and subsequent re-immersion of the cathedral into the sea. Observe the resolution of this episode, where dynamics passes from *ff* in 38 to *p* (42), *più p* (43), *pp* (44) and *più pp* (45-46).
The tower-top appearance on surface happens in measure 19 et seq, with some really marked notes on a rhythmic background based on triplets. In bar 23, it is the central nave that is emerging; the extended octave lines in Doric mode, first in right hand and then in left hand, followed by a pentatonic scale on the same D, allow us to calibrate their magnitude. Finally, the cathedral can be appreciated completely in bar 28.

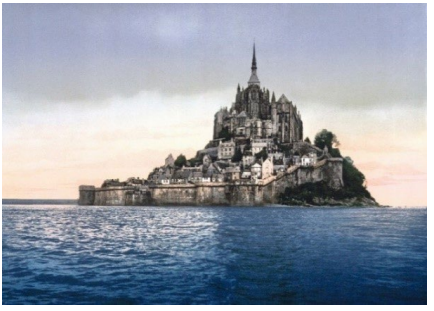

Figure 6. High tide in Mont Saint-Michel, France (c. 1900). Source: (old post card)

3.6. Atmosphere: sea and mist

Seascape is one of the favorite pictorial topics of Debussy and, in general, of all Impressionist painters. The poetic strokes that sketch the sound image of the sea focus mainly on its most sensory aspects, such as the uninterrupted movement of waves and the incidence of light on the surface.
In the case of the swell, the incessant rolling of the waters is evoked by the succession of ascending and descending chords, perhaps accompanied by rising bubbles, as if something was happening underneath.
As far as light is concerned, two characteristic and simultaneous phenomena converge. Firstly, transparency, which allows a glimpse of what lies beneath, for whose musical expression the level of intensity and tessitura are played, depending on the proximity to the surface of the sunken objects. Secondly, reflections or light flashes, recalled by sporadic replication of motifs or melodic material fragments. In this sense, the presentation passage of the temple (bars

28-38) could be tinged by the rays of sunrise, thanks to a greater harmonic and melodic clarity after the disappearance of the mist.
To represent the appearance of the mist with its aura of mystery, Debussy associates the idea of blurring or loss of visibility with that of fogginess or lack of sound sharpness. And this is achieved through harmonic vagueness, the absence of a clear melodic line, or the incorporation of pedal notes, which eventually make turbid the sound.
The atmosphere hinted at by all these phenomena could well be identified with some of Claude Monet's paintings, among which *Impression, soleil levant* (1872), the series of the London Parliaments (1900-1904) (Fig. 7) and the one of Rouan Cathedral (1892-1894) deserved to be highlighted.

CONCLUSION

Music has effectively a great capacity to evoke extra-musical contents: arguments, images, atmospheres, movements... In *La cathédral engloutie* all this is combined: the tale of an emersion, the representation of a mythical city, the recreation of an inner life, the evocation of a mysterious atmosphere... Certainly, the evanescent character of all music seems to fit perfectly with the ephemeral and instantaneous perception the impressionists were interested in. And Debussy, with his synesthetic ability and clever sensitivity, gets easily to transport us into a world of vibrant images, drawn in the air with sound brushstrokes.
Among the gamut of dreamy figures, there are also architectural ones: spires, main nave, perhaps an impressive façade..., that are aroused by a wide display of tools: scales, harmonic games, motivic and melodic material, rhythms, dynamics and other nuances... Based on this election, it would be said that the evocation of *La cathédral engloutie* is oriented towards a High Medieval Period rather than a paleo-Christian construction (Early Middle Ages), which would be in greater accordance with the chronology of the legend. Debussy's frequent visits to the island of Mont Saint-Michel may be at the base of this association (Fig. 6).
It should be reminded, however, that the music of this prelude is not purely descriptive. Not even the author could see directly the image represented, but only imagine it. Hence, his intention was not to predispose towards an accurate interpretation of the story but only to suggest it, leaving performers and listeners to build their own world of impressions.

PAPER #6.05

INTERVENTIONS IN SPANISH MONUMENTAL HERITAGE: A HOLISTIC VIEW OF BURGOS CATHEDRAL

Elisa Bailliet[a]
[a] Universidad Rey Juan Carlos, Madrid, Spain

ABSTRACT

Theoretical protection -derived from conservation theories and international recommendations and conventions on the protection of historical cultural heritage- as well as the legal protection of monuments, are as necessary as they are vain if they are not accompanied by intervention, whether conservation or restoration.
Based on this concept, the present document proposes that there is no protection without a thorough knowledge of the good itself and the recognition of monumental values brought together in it. This fact is evident in monuments of high complexity. An example of this is the huge sequence of interventions in the Cathedral of Burgos, Spain. Motivated by the obvious historical and artistic values, more than half a hundred projects were carried out during the twentieth century.
This work provides an overview of the interventions made in the Cathedral of Burgos during the last century, and demonstrates that a global analysis allows us to understand this process as a constant search for balance and coherence, not only theoretical but also constructive, structural, and aesthetic.

KEYWORDS

Heritage; restauration; cathedral of Burgos.

INTRODUCTION[1]

In recent decades, there has been an explosion of interest for the state of conservation of cultural heritage in general, and spanish heritage in particular. Also, generic and specific studies, analyses, and research, have proliferated to provide further information on monumental heritage. This, in part, originates in intervention projects, whether conservation or restoration, and there are many researchers from multiple disciplines who analyze the past of goods, theories, and interventions.
During the last decades, a premise has been frequently repeated about heritage: it is not possible to protect what is unknown or what is known superfluously.
We can try, and just try, to find partial solutions through partial knowledge, but we cannot protect all values encompassed in a monumental good without the integral knowledge of it. Though it seems obvious, this has not always been accomplished. From our perspective, this fact demonstrates that, there is a need to determine a minimum knowledge that was required in each intervention of historic buildings. This minimum turned out to be the Director's Plans, which have served and still serve today to gather the vast information disseminated along the centennial history of the largest monuments in Spain. This seems like an immense task ... and, in view of the historical results, it has certainly been.
But, before intervention, even before the recognition of the need for intervention, there is a stage subject to legal norms

[1] This paper is part of the research carried out for the preparation of the Doctoral Thesis entitled "History of the protection of architectural heritage in Spain. 1933-1985", presented in 2016, under the direction of Mr. José Luis García Grinda and Mr. Jesús Prieto de Pedro, in the Department of Architectural Composition. Escuela Técnica Superior de Arquitectura (ETSAM). Universidad Politécnica de Madrid. Spain.

and criteria that protect the Monument conservation, or at least try to. The legislative set of protection rules has evolved since the nineteenth century with the sole intention to be increasingly efficient. After two centuries of evolution, we can appreciate that the doctrine must be applied, and that its application is the intervention itself. Far from inaction or indolence, the intervention MUST materialize everything that, as a rule, the Laws require.
Therefore, it is a succession of several documental, legal, and constructive efforts.

1. SEVERAL GENERATIONS UNDER CONSTRUCTION

In 1221, the new Cathedral of Santa María of Burgos was built on a Romanesque temple that would remain, like so many others, encysted inside or under it.
It shows reminiscences of French Gothic style and is therefore related to other similar cathedrals such as those of Burgundy or León (Gonzalez-Varas Ibáñez, 1999), sharing the stonemason master, Master Enrique in 1240.
Hans of Colonia, who also participated in its construction, built the perforated spiers in 1442 which would become one of the hallmarks of the Cathedral, as recognized by Vicente Lampérez y Romea in the installation project of the lightning rod in 1892 (Lampérez y Romea, 1892).

2. INTRODUCTION TO CENTRAL ADMINISTRATION RESTORATIONS

The Spanish administrative management during the first half of the twentieth century, through the General Commissions of the National Artistic Heritage for the conservation of Monuments, was concentrated in some architects for a long period of time. Therefore, in spite of the absence of a comprehensive document that implied an exhaustive documentary and historical investigation as well as the monitoring and control of all past interventions, knowledge of the monumental good was extensive and intense. This allowed that the works would follow a logical way, based on a planning that, far from being anarchic, has been progressive.
The same as for so many other monuments, the administrative organization, according to a geographical zoning, allowed some continuity of architects in charge of conservation and restoration works in the Cathedral.
Between 1942 and 1944 Francisco Iñíguez Almech, Director of Monuments of the National Treasury of Art, was in charge of interventions. From 1948 to 1963 he was replaced as architect of the monument by Anselmo Arenillas, who was followed by José Antonio Arenillas Asín (Assistant Architect of the 2nd zone). In 1978, Francisco Iñíguez Almech carried out two works, but the remaining ones, more than twenty restoration projects for the Cathedral, were performed by Marcos Rico Santamaría between 1976 and 1990.
The last restoration of the Cathedral of Burgos in the 19th century was carried out by Ricardo Velázquez Bosco in 1898. From then on, for almost twenty years, Vicente Lampérez y Romea intervened different areas of the monument. In 1929, J. Apraiz made the consolidation of the South needle.

2.1. Interventions on the roofs of Burgos Cathedral: the fundamental link for integral conservation

If the construction of a "building" lasts more than four centuries, it is apparent that the restorations alternate with the construction. In that case, we have to admit that some interventions have not recorded its imprint because they have been made interspersed and mimicked with the construction itself. According to the data provided by García Escudero and Hernández Gil in the 1995[4] intervention project, the first restorations was carried out in 1692 in the towers, followed by

the "Pellejería" (1516), the reconstruction of the dome (1539-1567) and the reform of the cruise of the cathedral (1642 and 1664).

They were followed by a multitude of cases with diverse objectives and incomparable magnitudes, from needles to reliefs, from facades to traceries and ornaments, which will be the subject of other studies.

But in 1948, although it had been proposed in some previous project and as an emergency plan, begin forty years of restoration works in all the roofs of the complex, alternating with works in other constructive and decorative elements.

By 1910, Vicente Lampérez y Romea had restored the covers of the Chapel of the Constable and the lower nave of the south side, with a budget of 18,732.89 pesetas, but unfortunately it has not been possible to access the documentation of the project, which prevents us specify the magnitude of such an intervention.[2]

Also, in 1929, Apraiz undertook the timely restoration of the cruise deck, as part of a general intervention.

But it is in 1942 when we began to recognize the interventions in the real problems of the roofs, starting with the project of Francisco Iñíguez Almech (Iñíguez Almech, 1942). In this project he faced the repair of the pavement of the low cloister and recognized that his roof had leaks and that it was necessary to restore it, although only the "review of the zinc cover" was indicated.

A few years later, in 1948, Anselmo Arenillas (Arenillas, 1948) insisted on this situation again, which let us infer that the tasks carried out proved insufficient.

As Iñíguez Almech explained in the project in 1963, almost twenty years later, the rains of the previous year had deteriorated the tissues of the whole, so he proposed the restoration of the roof of the Chapel of Santiago, such as the side skirt from the Chapel of Santa Tecla. This restoration involved the replacement of 40% pairs of the roofs, around 500m2 of planking, and with 50% use of the roof tiles.

Despite this, a year later José Antonio Arenillas Asín (Arenillas Asín, 1964) proposed the reconstruction of the cover of the Condestable Chapel due to the great deterioration detected (loss of section due to the presence of xylophagous insects), which compromised the structural stability of the cover, and put at risk the vaults and arches. The reconstruction proposed involved the construction of a metal structure with articulated anchors to avoid the transmission of effort when the material dilated.

It should be noted that this change in the construction system proposed by Arenillas Asín in his project, the replacement of a wooden structure by a metal structure, minimized the possibility of a fire like the one in Notre Dame Cathedral, in Paris, in 2019.

Obviously, the situation of the Condestable Chapel was no exception, and in 1966 Arenillas detected that this state of consummate ruin, not incipient, had repeated in the cover of the Chapel of Santiago (Arenillas Asín, 1966).

This situation would continue over time, and in 1976 architect Rico Santamaría presented three new roof repair projects of the lateral naves of the Chapel of "San Nicolás", the Chapel of "La Natividad" and the Chapel of "San Antonio" (Rico Santamaría, 1976a), "Santa Ana" and "Santa Tecla".

In addition to the structural replacement, the vaults were reinforced by a water-repellent concrete coating to minimize the possible leaks of the roof, and the stone material of the coronation of the walls was consolidated.

Due to the structural unit of the roof of the Chapels of Santa Ana (Rico Santamaría, 1976b) and Santa Tecla (Rico Santamaría, 1976c), the project for the roof replacement of the latter was prepared on the same year. On this occasion, and with the double objective of facilitating water evacuation and minimizing its effect on the left tower, and also visually freeing the flying buttress and the tower, the

[2] General Archive of the IPCE, Ministry of Education, Culture and Sports, Madrid, and General Archive of the Administration (AGA), Alcalá de Henares. Consultation period: January and February 2012.

project proposed the reconfiguration of the roof to four waters. The project contemplated the protection of the churrigueresque dome through an internal formwork with minimal impact on the surface.

The project also contemplated the restoration of the stones of the wall, as well as the provision of isolated zinc gangways to prevent the tiles from stepping on. The exterior stone walls would also be repaired, covering them with a coat of transparent and matt silicate paint as protection against future erosion.

From the general analysis carried out by Rico Santamaría, there is evidence that the roofs were in a state of poor conservation and that it was necessary to undertake successive restoration works that, could involve the dismantling and reconstruction of some zones.

In general, and due to the structural similarities of the roofs, the conservation problems were similar throughout the whole building. The leaks in the vaults and the consequent deformations, as well as the appearance of damp in adjacent walls would cause the wooden structures to be replaced by a metallic one. Besides this reconstruction, the stone material of the walls had to be also restored by means of stapling and grating at the coronation.

In the same way, the roofs of the central nave of the apse, both lateral naves, and the passage of the Chapel of the "Condestable" (Rico Santamaría, 1977b), respectively, were intervened.

Two years later, in 1979, two projects were drawn up with the objective of partially restoring the roofs of the Cloister, in the area near the Chapter House (Rico Santamaría, 1979a) and in the Sarmental (Rico Santamaría, 1979b) area, respectively. In both works, the wooden elements were replaced by metal belts laminated with a hollow ceramic vault board, with the corresponding compression layer and double metal mesh. These projects proposed to reduce the slope from 45% to 33% and replace the flat by the curved tiles. In the opposite sides, in the area near the chapel of Santiago and San Enrique, roofs of one water with a 10% slope and covered

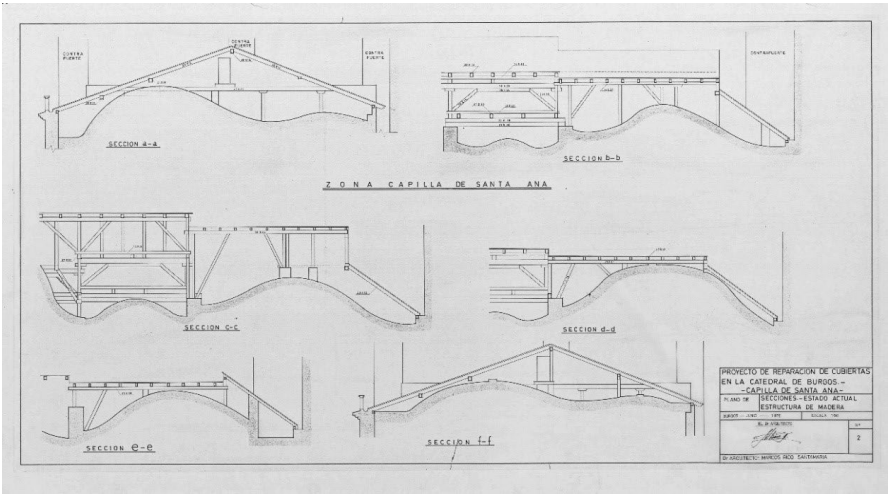

Figure 1. Detailed plan of the roof repair project in the Cathedral of Burgos. Chapel of Santa Ana. Current State. Architect: Rico Santamaría, M. Date: March 1976. Source: IPCE General Archive. IPCE Planoteca. Ministry of Culture and Sports. Spain.

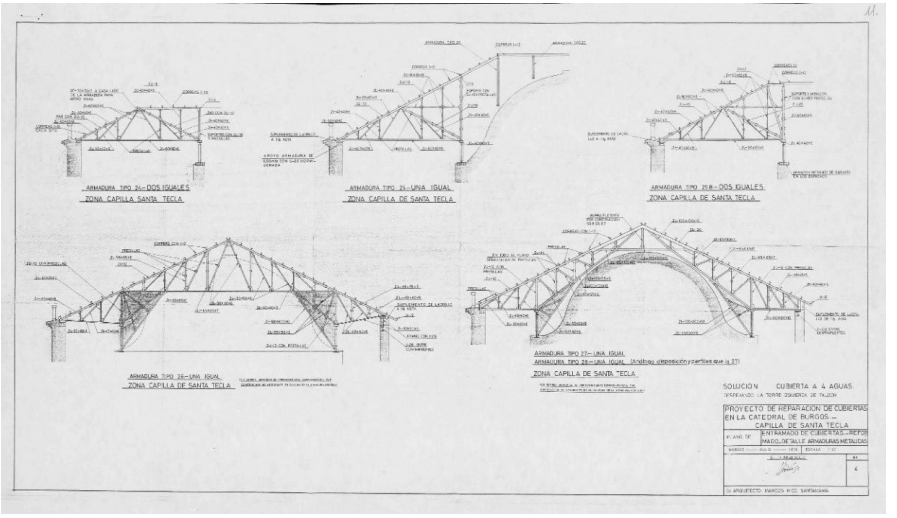

Figure 2. Detailed plan of the roof repair project in the Cathedral of Burgos. Chapel of Santa Ana. State reformed. Architect: Rico Santamaría, M. Date: March 1976. Source: IPCE Planoteca. Ministry of Culture and Sports. Spain.

by zinc sheet were renovated. In addition to the replacement of downspouts, valleys, and gutters, access doors to the galvanized sheet platform would be incorporated, plastering the skirts with water-repellent mortar.

That same year, at the end of 1979, Rico developed two complementary projects in which he proposed the partial repair of the roofs of the Anterior Central Nave, in Plaza de Santa María, the left front lateral nave (Rico Santamaría, 1979c) and the roofs of the towers, and the right lateral nave (Rico Santamaría, 1979d).

The following year, efforts were focused on areas that had not been previously intervened, covering 1,657 m2. Thus, the project for the partial repair of the roofs of the Burgos Cathedral (Rico Santamaría, 1980) was proposed, including several areas like the Chapel of the Remedies (or of the Holy Christ of Burgos), the Dressing Room of the Canons, and the Sacristy of the Chapel of the Presentation, the Chapels of the Presentation, of the Relics, of San Juan de Sahagún, and of Santa Isabel, the South arm of the transept, the Chapel of San Enrique, and the Vestibule of the Sacristy.

The intervention consisted in the application of the same technique of substitution of the wooden framework by a metallic structure of laminated profiles, the restoration of the accessory elements of the roof. Unlike other sectors, this area presented unevenness and access to the below deck, so access skylights would be incorporated. This solution makes it possible to bridge the gap between roofs and vaults without it being perceived from the outside.

In 1981, while the works in the nearby areas were being completed, the General Directorate of Fine Arts, Archives and Libraries of the Ministry of Culture commissioned Rico Santamaría a new project (Rico Santamaría, 1981) for the restoration of 2,014 m2 in order to conclude the repair of the Cathedral roofs. This new project included restorations in six priority areas which were located in the Sacristy of the Main Chapel, the roofs

of the transept lantern, the Chapel of the Condestables, the Chapel of Santiago, that of Santa Catalina and the Archive (on the Chapel of Corpus Christi), access to the archive (on the Chapter House), and the Engine Room and boilers.

As with all covers, the protocol was limited to the protection, replacement, and adaptation of covers according to their state of conservation, the degree of deterioration, and the material used.

For years, Rico Santamaría dedicated himself to restoring and rebuilding the roofs of the cathedral with the aim of stabilizing and updating the structures because, as he himself indicated in the project, "All the roofs of the Cathedral have been studied conscientiously to free them from their deplorable state, ..., having given an effective remedy to all of them." (Rico Santamaría, 1981. Pág. 2)

But this complex and methodical process would culminate in one of the most visible tasks, such as the intervention in the cruise ship's lantern. This element, rebuilt in the 16th century by Juan de Vallejo, had a plementery with openwork hidden by a framework. Such a sculptural filigree deserved special attention, literally, "... if there is one in which that scrupulous study has to be taken to the extreme, it is this one, the lantern in the transept." (Rico Santamaría, 1981. Pág. 2). This scrupulous study consisted of verifying the state of conservation of the roof elements, the decision to maintain the beams that supported the framework that was to be removed, "... as a relic of other times ...", the estimated calculation of the self-weight of the structure and the need to lighten it without intervening the openwork plementery.

Likewise, the placement of three skylights per triangle roof, a total of twenty-four Stadip skylights on the octagonal roof, was proposed with a double mission of lightening the roof and illuminating the delicate works of Juan Vallejo.

CONCLUSIONS

In the last decades, some studies have suggested that the works carried out in the Spanish monumental heritage during more than half of the 20th century had not followed any planning and that, on the contrary, they had been the result of impulses motivated by emergencies. It is true that, on many occasions, the appearance of pathologies of variable magnitude and importance has marked the sequence of works in many heritage assets. But, in contrast, some monuments have gone through a process of exhaustive analysis through which priorities were identified that guided the intervention process.

Gradually, interventions in the Cathedral of Burgos have been linked to a strategy of structural stabilization and roof consolidation, and this was demonstrated by the progression of the works carried out on the roofs by Marcos Rico Santamaría.

The Cathedral of Santa María de Burgos is one of the most intervened Spanish monuments over the last three centuries. Altogether, numerous works of all kinds, size, and budget have followed one another. All this with the sole and essential purpose of maintaining, preserving, safeguarding its integrity and that of the artistic, historical, architectural, and sculptural elements: to preserve their cultural values.

This monument, declared by Royal Decree of April 8, 1885, would take a century to be declared a World Heritage Site in 1985. During that century it became one of the hundreds of pampered goods, in the best sense, of Spain. And, for this reason, it was recognized by UNESCO in the best possible state thanks to, at least, sixty-four projects of various kinds.

It has been speculated that the tragedy occurred at Notre Dame of Paris could take place in one of the Spanish Cathedrals. It would be naive and reckless to deny emphatically that any disaster could occur

in the Spanish heritage, but in the light of data available, after centuries of meticulous and effective care, the possibilities seem drastically reduced and that image, less likely. Or at least we hope so.

PAPER #6.06

THE ROLE OF KNOWLEDGE TRANSFER IN MASONRY BRIDGE CONSTRUCTION FROM SPAIN TO GUATEMALA

Sandra Hernandez[a], Ahmed K. Ali[a]
[a] Texas A&M University, College Station, TX

ABSTRACT

By the 16th Century, transportation networks played a vital role in the urban growth of many settlements during the Spanish colonization in Guatemala. Consequently, the construction of masonry bridges ran parallel to the regional trading networks. Beyond its humble simplicity, expressed in the use of local materials, such as stone and bricks, these bridges resulted from technological advancements that fostered cultural, social and knowledge exchange between the Spanish colonists and the local Mayan Indigenous. Moreover, the construction of masonry bridges included a complex process of knowledge transfer among both cultures. Interestingly, little has been written about the still-standing Colonial bridges, which have not always been the primary focus of preservation efforts. The influence of both cultures on the masonry bridge's construction during the 16th Century in Latin America is one critical question in revealing its construction history yet to be answered.

This paper builds on an ongoing doctoral research that intent to investigate and document both the Las Donadas Bridge in Montoro, Spain, and the Los Esclavos Bridge in Santa Rosa, Guatemala. This study attempts to understand the non-verbal reflections of history through the physical characteristics, materials, and constructive methods of each bridge. Ultimately, the goal is to build a comparative analysis using three material and construction elements of a bridge, such as stone, arch, and abutment. A qualitative case study approach incorporates historical archives, field observation, survey, and photography. Each structure is expected to provide a greater knowledge of the cultural influences and the apportioning of both cultures' craftsmanship during the Los Esclavos Bridge construction.

KEYWORDS

Knowledge transfer; bridge construction; stone; arches; Colonial Period.

INTRODUCTION

In the 15th Century, during the Exploration period, Spain invested an extensive effort to expand its empire in America. Previous experiences in warfare strategies, including technological advantages such as weapons and horses, gave Europeans the superiority over Indigenous groups. Consequently, Spanish conquerors became experts in incorporating strategies of colonization throughout America. During this period, the encounters between local ideas and foreign ones created a hybrid exchange of knowledge between both Mayan Indigenous and Spanish cultures resulting in new cultural entities (Headrick 1988). This interweaved cultural integration was developed to fit local conditions through many areas of life. For example, the Spanish Colonization in Guatemala reveals a sum of new intangible manifestations expressed by language, faith, and folklore. In conjunction with tangible entities, such as architecture, cuisine, clothing, and building technology, all together became the cultural legacies between the Mayan and Spanish cultures.

In the 16th Century, the Colonization period started a new wave in building technology and infrastructure. It coincides with the development of a transportation system and the construction of masonry arched bridges. Few scholarly writings have been focused on the role of infrastructure related to colonization. One influential work is "The Tools of Empire" by Daniel Headrick. In his book, Headrick pointed out the impact of technological advances in transportation and infrastructure as elements of colonization in the new environments. Although the work focuses on the transfer of knowledge in technology, it is framed within the 19th-Century European context (Headrick 1988). Even less has been written about the role of the masonry bridges as elements of technological innovation in the context of the Colonial period. One crucial structure for this research is the Los Esclavos Bridge, found in a small village located in the Department of Santa Rosa on the southeastern Guatemalan territory. The masonry bridge's construction was primarily carried out by the Xinca Natives, one ethnic group within the Mayan civilization (Recinos 1984). To inquire into the role of knowledge transfer and the requirements to build the structure, first, it is necessary to know about the source of hand-labor and source of knowledge prior and during its construction. At the same time, it is essential to know the materials, methods used for its construction. Therefore, one section of this analysis provides a general background for each bridge undertaken. The other section offers a technical analysis of both structures to compare about their visual characteristics.

1. METHODOLOGY

The interdisciplinary nature of this research requires the need to analyze different fields, theories, and concepts, from a subjective perspective. Therefore, it is based on the comparative analysis of qualitative case studies. The focus of this approach is to develop an in-depth understanding of two units of analysis, represented by two historic bridges. This model will explore the phenomenon of transfer of knowledge through the architectural lens to demonstrate repetition, patterns, and commonalities between both cases (Merriam and Merriam 1998) The first bridge which will serve as a benchmark is the Las Donadas Bridge, located in Montoro, Spain, built approximately between 1498 and 1544. The second bridge that acts as an embedded (in-depth) entity is the Los Esclavos Bridge, located in Santa Rosa, Guatemala, built between 1592 and 1600. Los Esclavos case received a broader perspective of analysis with a more in-depth understanding of the factors that affected its construction (Scholz and Tietje 2002). The goal is to use the findings as a starting point to establish the patterns and interrelations between the Spanish and the local Indigenous, to argue the established assumption that the process of knowledge transfer ran only one way as imported and blueprinted from Spain. The research methodology included the following tasks: To establish the time-frame: built between 15th and 16th Century (based on Los Esclavos' date of construction in 1592) To select the geographic location: Guatemala and Spain (to display the sequence of events from Spain to Latin America) To generate a survey and analysis: based on bridge typology construction method, arch configuration; span range; length; function or utility; architectural features, such as construction materials: Masonry, stone, and brick To organize the acquired data. To draw the conclusions.

2. BACKGROUND

This analysis presents general information of the Indigenous and Spanish technological developments that influenced the construction of the Los Esclavos Bridge. As well, the historical background of the

locations where the bridges' construction took place. De-winding those factors together with the stone, arch, and abutment technical analysis will help create a holistic view.

2.1. The Mayan Indigenous' Influence

The region of Guatemala is the center of the ancient Mayan civilization. It is documented that during the time of the Spanish conquest, Mayan builders already knew the corbeled arch method, which they used to construct vaults. This particular spanning system is also known as the Mayan arch, designed to cover rectangular spaces and support the stone ceiling (e.g. Fig. 1). The Mayan arch system is based on the cantilever principle that relies on an offset horizontal stone projecting beyond the one underneath (Gilabert Sansalvador 2018). Simultaneously, the horizontal stone layers create an inverted "V" shape over a linear axis (depicted as stepping stone stairs in cross-section). Unlike the semicircular Roman arch, the Mayan arch's construction was less complex because it only worked under gravity loads or by axial forces; therefore, it was also known as a false arch (O'Kon 2012). Researchers believe that Mayan builders relied on two different methods to achieve this effect during construction. First, the synchronized construction of the exterior and interior masonry walls served as a mold or framework for the core fill-in material, usually ruble. Second, the internal thrust beams built with timber were designed to serve two purposes; as a scaffolding to reach heights fixed to remain-in place after completion and as an axial shear reinforcement of the arch (e.g. Fig. 1).

While the Mayan builders took advantage of their local resources efficiently, using mostly limestone, clay, and timber founded in the surroundings (Wernecke 2005), recent research demonstrated that the Mayan builders used a different method for building bridges across a major rivers. According to the archaeologist and engineer James A. O'Kon, the archeological remains found in a Mayan site called "Yaxchilan" demonstrated that they used a combination of a suspension rope-cable method aided by two a passing-through masonry towers and anchorages to each side. (O'Kon 1995). Because of the structural advantages of this system that allow longer lengths, the Mayan were able to build a bridge with three continuous spans for a total length of approximately 182 meters (approximately 600 ft.) over the Usumacinta River, which defines the border between Guatemala and Mexico.

2.2. The Europeans' Influence

Roman builders were considered as the fathers of the masonry arched bridge's construction that were built throughout Europe. When the Romans conquered Spain, they brought their knowledge of civil engineering to that region. Consequently, the history of bridges in Spain's western part was influenced by both the Roman and Moorish cultures that occurred the land.

Similarly, since the Spanish Empire colonized Guatemala, it was expected that the knowledge of bridge-building technology was an adaptation and incorporation of both cultures, the Spanish and the Mayan Indigenous.

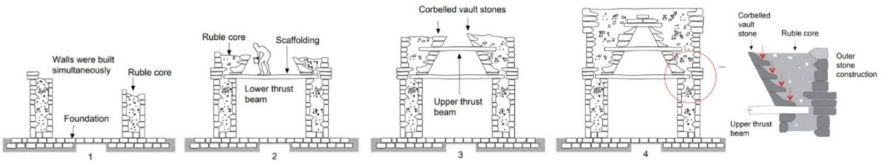

Figure 1. Construction process of the Mayan arch based on O'Kon sketches. Source: (Author 2020)

One crucial example of this technology is exemplified in the Los Esclavos Bridge, found in a small village located in the Department of Santa Rosa on the southeastern Guatemalan territory. It is undeniable that the Los Esclavos Bridge is a clear example of European colonists' intent to introduce their constructive methods in the new environment. For the first time, the Indigenous of Guatemala were introduced to the production and technology of fired brick and semicircular arched masonry structures. These skills and knowledge were passed down from Spanish builders and masons to the local artisans and then to their new generations (Fraser 1990). In Spain, similar structures were constructed in the Cordova and Extremadura regions, near the Portugal's border. One example is the Las Donadas Bridge, located in Montoro, Cordova (e.g. Fig. 2). Despite the two structures being built more than 150 years apart, and different continents with a distance of approx. 8,690 km from each other, the most visible characteristic of comparison are their physical configuration and surface qualities such as material and craftsmanship.

2.3. Las Donadas Bridge as a benchmark case study

The Las Donadas Bridge, located in Montoro Village, Province of Córdoba, Spain, carries the Cedrón road over the Guadalquivir River. The bridge's original name was Puente Mayor, which means "Major Bridge" in the English language. The exact dates of its construction have not been determinate. However, according to Jose Ortiz Garcia, a researcher from the University of Córdoba, it is estimated that the bridge construction lasted for nearly over 40 years between 1498 and 1544. There is the possibility that Enrique Egas, an architect from Brussels, was in charge of the design and the construction under the direction of a master of works named Pedro Fernandez (García 2006).

Portion of the funding for its construction came as a donation from the Montoro's inhabitants and neighbor communities under the justification of regional financial benefit (García 2006). For this reason, the bridge was called El Puente de Las Donadas or "the bridge of the donated" in the English language. According to Daniel Vela, historic bridges in Portugal and Spain that belonged to the Roman political system were regulated by pre-established rules that define their craftsmanship and materials and not by local conditions (Vale 2019). One of these rules dictated that a bridge must be wider than 5 meters (approx. 16.5 feet) to allow the Roman mounted troops to campaign and commercialize. Here, it is necessary to remember that back in the 15th Century, the typical transportation method in Spain and Europe was by horses and carriages, which justified the 5 meters bridge's width ruling. Despite the present technological advances in transportation, the Las Donadas

Figure 2. Left, Las Donadas Bridge, Montoro, Spain. Source (Garcia 2008). Right, Los Esclavos Bridge, Santa Rosa, Guatemala. Source (Author 2018). Two remarkable technological innovations from 15th and 16th Century.

Bridge still serves its original purpose. The 29 feet width clearance of its road is enough to accommodate a two-way vehicular traffic and the pedestrian circulation (Table 1). During special events, the bridge modifies its function and becomes part of the Montoro's community space for an open social events and celebrations (e.g. Fig. 3).

2.4. Los Esclavos Bridge as an embedded case study

As colonists began to establish new foundations, it became necessary to connect those settlements that were part of the Viceroyalty of the New Spain (now known as Mexico, Guatemala, and much of Central America). Before the year of 1592, colonists who traveled the southeastern mountainous area of Santa Rosa, Guatemala, encountered a raging river that caused a loss of time, human resources, and money. Those reasons were the primary motivation for constructing a masonry-arched bridge that would withstand the violent waters, especially during the rainy season, providing a fast and easy method to safely cross over the river for all the traffic operating during that time. The arched bridge's construction was executed by the Xinca Natives, who were enslaved to serve the colonists. Based on the chronicles of Bernal Diaz del Castillo, a traveler historian, the Xinca were the first slaves formally assigned to conquerors in that area (Tom. II, Tratado IV, Cap. XXII, from the MSS. of Fuentes). For this reason, the small village, including the river and bridge were named Los Esclavos, which means "the Slaves" in the Spanish language. Its construction began approximately on February 17, 1592, and was finished in the year 1600. Unfortunately, there is no known document describing the construction process or an inventory of the people who participated in its construction, which what makes this study important to reveal the construction story of that bridge.
During that time, the primary means of transportation were either riding a horse or a wagon pulled by oxen. Therefore, the three meters width of the Los Esclavos Bridge allowed just one-way traffic at a time (e.g. Fig. 3). The access ramps on each side of the roadway probably functioned as a waiting zone for travelers, cattle, and merchandise to cross over (Table 1). Similar to the Las Donadas Bridge, the construction of the Los Esclavos Bridge was partially funded by a taxation policy; in this case, a tax was applied to bottles of wine (Hemeroteca PL. 2017). Over time, the bridge's economic benefits became visible to the surrounding area, and the Viceroyalty of Santiago de los Caballeros in Guatemala located 40 miles away from the site (de Administración Tributaria 2009).

	Las Donadas Bridge	*Los Esclavos Bridge*
Location	Montoro Village, Cordoba, Spain	Los Esclavos Village, Santa Rosa, Guatemala
Length Approx.	180 Meters/590.5 Feet	89 Meters/293 Feet
Width Approx.	9 Meters/29.5 Feet	3 Meters/10 Feet
Height Approx.	19.5 Meters/62.3 Feet	11 Meters/29.5 Feet
Number of arches	Four (4)	Eleven (11)
Latitude and Longitude	38°01'37.4 N / 4°22'63 W	14°25'10 N / 90°27'42 W

3. TECHNICAL ANALISYS

3.1. Abutments

Both bridges appear to have similar abutments in their design and geometric configuration; perhaps their arrangement is one of the most common elements. While the structural analysis of the bridges is out of the scope of this research, it is necessary to provide a general explanation of the acting forces to justify the role of abutments on the bridges. Structurally, semicircular arches transfer loads in a vertical direction, and segmental aches transfer the loads in an inclined direction to the supporting piers and abutments (Huerta Fernández 2001). The Los Esclavos Bridge involves a combination of both type-arches, five semicircular, and six segmental arches that form the barreled vaults. The piers located on either side of the vault receive upper loads and bring them to the foundation. In conjunction with the piers, the abutments have three main functions; first, to absorb half the weight of each adjoin barreled vault; second, to resist the side forces created by the load on each vault; and third, to provide equilibrium and stabilization to the bridge in the horizontal direction (Apreutesei and Oliveira 2005). The presence of sharp edges on the upstream abutments serves as a hydraulic approach to redirect and lessen the upstream river flow's impact against the spandrel wall. Further, it deviates the floating debris by controlling the flow passing through the barreled vaults' openings and between piers. The upstream abutments in both bridges present the same principle. The abutments in the Las Donadas Bridge have only two plan configurations and fewer abutments; three are ogival and three semicircular. On the upstream façade, two of the ogival abutments are full height up against the road level, and a third is with half-height; some scholars suggest that it was never finished. One unique element of this bridge is that two full height ogival abutments became a balcony at the road level, modifying its function and providing pedestrian access for a lookout. This particular experience enhances the relationship between landscape, bridge, and the user. The semicircular abutments are built on the downstream façade. Each abutment is elevated until half the height of the bridge. After this point, the semicircle flat-based rises to a conical cap ending towards the spaniel wall, where it reaches the pinnacle (table1). Differing from the Las Donadas Bridge, the number of abutments in the Los Esclavos Bridge increased significantly to nineteen (19). All of them have a full-height; however, there is no pedestrian access. As expected, all the upstream façade abutments (east) have sharp edges, however, their plan configuration is distributed to seven triangular and two more in a trapezoidal shape. On the downstream façade, the plan configuration changes to seven semicircles and three trapezoidal shapes (table1).

Abutment	Las Donadas Bridge			Los Esclavos Bridge		
Location	Plan shape		Height	Plan shape		Height
Upstream façade	Three (3)	Ogival	Full (2)	Seven (7)	Triangular	Full
			Half (1)	Two (2)	Trapezoidal	
Downstream façade	Three (3)	Semicircular	Half	Seven (7)	Semicircular	Full
				Three (3)	Trapezoidal	
Total	Six (6)			Nineteen (19)		

Table 2. Distribution of abutment in both bridges, by plan shape, façade and number of units. Source: (Author 2020)

3.2. Arches

Contrary to the Mayan corbeled arch, the construction of a semicircular arch involves the use of a temporary framework in the form of mold to guide the construction as the arch gets shaped. The curvilinear shape of this deck not only provides stability, but also supports the dead weight of the materials, and maintains the semicircular shape of the upper unfinished vault-structure until it acquires the strength to support itself. In the Los Esclavos Bridge, five central barreled vaults have a series of small holes embedded on the walls along a horizontal axis as evidence of this procedure. By definition, those holes are known as "putlogs" it was a prevalent practice in masonry historical bridges (Curl 2006). Their consistent rectangular shape and their size indicated the possibility of perpendicular beams that penetrated the walls to support the curved platform's ends. However, there is no specific information about the material used for this purpose. It would be possible they used timber or bamboo as part of the framework and scaffolding since the grass grows in the area. Bamboo is a common material in Guatemala that is fast growing and can be up to 30 centimeters (12 inches). The Las Donadas Bridge is composed of four semicircle arches, all with different spans that support the 180 meters-long deck. This structure works on the basic principle of semicircular arches; the load and forces are transferred in a vertical direction to the piers, which was previously explained (e.g. Fig. 4). This was the technology that the Spanish Colonists brought to New Spain. The Los Esclavos Bridge has eleven arches to support the structure, distributed along a linear axis approximate 89 meters long (293 feet). Each arch became a barreled vault to carry the single-lane deck, defined by the three-meter width (approx. 10 feet) of the road above. The facades have five semicircle arches and six segmental arches

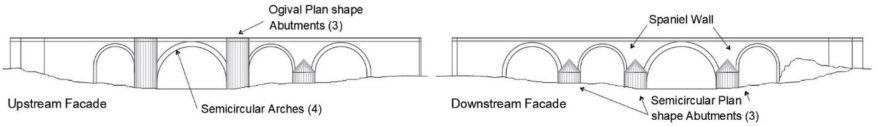

Figure 4. Left, Upstream Façade Las Donadas Bridge. Source (Author 2018) Right, Downstream Façade of Las Donadas Bridge. Source (Author 2020)

in elevation, each with different height and span to accommodate the uneven terrain. The role of the framework (or mold) in the construction of the Los Esclavos Bridge was essential for the learning of the local carpenters and builders who became acquainted with the new arch principles. This historical structure is sober in decorations, but it is evident they used an appropriate and well-constructed framework, which allowed a structural sound bridge when it comes to its efficiency. Despite torrential rains during wet seasons and the constant earth-shaking, this structure still stands to attest its exceptional craftsmanship, passed from the expert European master to the novice Mayan Indigenous builders (e.g. Fig. 5).

3.3. Stone of the Las Donadas Bridge

The village of Montoro, Spain, is well known for using a red colored stone in its buildings and ornamentation around the town. The Las Donadas Bridge was built with a local stone classified as lithotype known as "Molinaza Roja" (Molina et al. 2015). It is unquestioned that the Las Donadas Bridge's construction involved a considerable amount of labor not only in preparing the cut stone but also arranging the ashlar setting at the site. It was finely worked to produce a masonry system predominantly made of rectangular and square ashlar blocks. Although the structure was carefully built from start to finish, visually, it exposed two particular patterns. The upper section starts from the top of the handrail down to the road level. The lower section starts from the road level, down to the foundation (e.g. Fig. 5-b). Both upper and lower sections are separated by a continuous horizontal sill located approx. at the bridge's road level. This sill is projected from the spaniel wall and extends to the bridge's entire length in both facades. The upper section presents a modular system crafted into consistent stone blocks. Detailed stonework was applied to precisely lay the stone and neatly to address the handrail's edges. All three rows of the handrail wall are well proportioned and balanced for a uniform ashlar configuration, including the robust capstone that matches the wall pattern (e.g. Fig. 6-a, and 6-b). The size of the joints are consistent and relatedly thing that the mortar is almost invisible. The lower section presents a different modular arrangement (e.g. Fig. 6-c). Most of the blocks were laid horizontally and maintained the interlocking system between each row. However, each row has a different height related to the other (e.g. Fig. 6-c). In some cases, the stone units were laid in a random pattern, sometimes facing the headers and others facing the stretcher, but keeping the same height through the entire course. The changes in the ashlar configuration could be the product of an intermittent sequence of construction. The present findings suggest that the craftsmanship applied to the Las Donadas

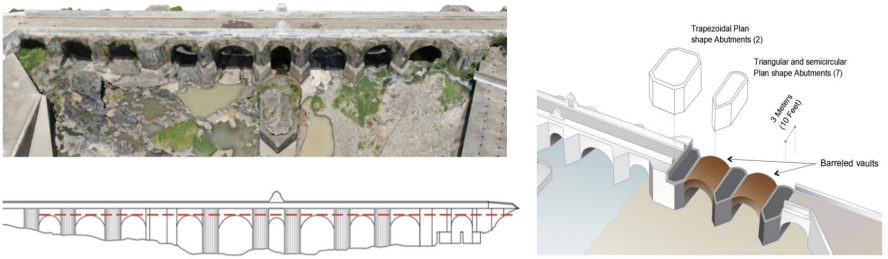

Figure 5. Left, Upstream Façade of Los Esclavos Bridge. Source (Author 2018) Right, 3Dimentional model of Los Esclavos Bridge. Source (Author 2020)

Bridge and its work's magnitude might significantly influence its 40 years of construction. Both sections' patterns balance the bridge; the lower part was designed for general serviceability. Based on the visual characteristics of the upper section, it suggests the use of sophisticated craftsmanship and material hierarchy compared to the lower section. Perhaps, the upper part was influenced by the relation between pedestrians and the bridge, to please and enhance the people's experience.

Stone of the Los Esclavos Bridge

The masonry stone system of the Los Esclavos Bridge is mainly composed of rubble stone except for the arches, barrel-vaults, and handrails that were made of brick. In some cases, the use of rough-cut stone was implemented to create specific elements of the bridge, such as the abutments, corners, and edges. The pattern configuration of the stone is varied and improvised. It is speculated that the Indigenous hand labor resolved the issues instinctively as it arose. The stones were laid with the intention of horizontal rows; however, not all the times it was achieved. The overall character of the bridge depicts a massive and permanent structure. However, visually at close range, the sober character of materials exposed an assemblage of emergency as if the constructors whisking to build the bridge as soon as possible. Further, the timeline coincided with the socio-political situation of the region at that time of its construction. Compared to the Las Donadas Bridge, the differences of the masonry stone system of the Los Esclavos Bride became evident at first sight. While the Las Donadas was built with red ashlar stone, in an almost perfect square-cut arrangement, the Los Esclavos Bridge was constructed with available local materials such as uncut rubble limestone in an irregular pattern configuration (e.g. Fig. 7).

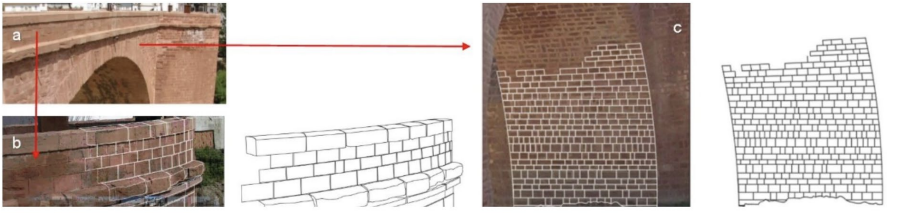

Figure 6. Upper and lower masonry stone system in Las Donadas Bridge, Montoro, Spain. Source (Garcia 2008) (Author 2020)

CONCLUSIONS

The results of this analysis highlight several visual characteristics among the two bridges. These findings will lead to support or refute the hypothesis that the knowledge applied to the construction of the Los Esclavos Bridge is the adoption of European technologies. Similarities and differences in characters, and construction techniques might be summarized as follows:

Similarities:

Based on typology, both bridges showed a close relationship in their components, such as incorporated abutments, barreled vaults, massive handrails, and spandrel walls protected by colossal abutments. Although the abutment's plan configuration differs in each bridge, they are related by the same principle of sharp edges facing upstream river flow. The same situation happened on the downstream façade, where the principle of smooth semicircle abutments is evident. Also, each bridge presents a symmetrical number of abutments in both the upstream and downstream facades. While the number of arches and the type of building materials are different, the principle of an arched masonry structure is still the same. They shared the same structural principles, by transferring the weight loads in a vertical and inclined direction to the piers, then to the abutments, and lastly to the foundation.

Differences:

The most visual difference between both cases is based on craftsmanship and the pattern arrangement of the stone. The surfaces of the Las Donadas Bridge present more elaborated and smooth stone craftsmanship. Logically, Spanish builders had hundreds of years of practice in the making of masonry arched bridge technology. Spanish trained craftsmen had a superior advantage over the novice and informally trained Maya Natives. In terms of construction length, the Los Esclavos Bridge took less time to build (ten years), probably due to three important facts. First, the bridge's proportions are smaller; this involves fewer materials, less financial inversion, and less hand-labor compared to the Las Donadas Bridge. Second, the purpose of the bridge was to serve the necessity of crossing the river; its materials, ornamentation, and labor were applied accord to its function. Lastly, it is speculated that the amount of hand-labor provided by Mayan-Xinca Indigenous and African slaves was substantial at the time of the bridge's construction. Both bridges differ by the number of arches and abutments in their physical composition. Although the Los Esclavos Bridge is significantly smaller in its dimensions and proportions, it has a greater amount of elements such as eleven arches and nineteen abutments. The Los Esclavos Bridge presented a high degree of uneven stone configuration. There are many possible explanations of this craftsmanship issue, such as variations in builder's crew skills, hand-labor shortage, economic funding struggles, or quarry location changes. Further, the use of raw stone reflects its experimental status, challenges faced, and the Indigenous' problem-solution skills when issues arose. The level of sophistication of the Las Donadas Bridge's craftsmanship and technology correlates well with Montoro, Spain's socio-political context. Oppositely, the stone's size variations and the improvised pattern arrangement of the Los Esclavos Bridge reflect the historical circumstances when the bridge was created, characterized for economic manipulation, forced labor, and slavery against the Indigenous population. Two reasons might influence plaster usage as a final finishing on the surfaces in the Los Esclavos Bridge. First, to cover up the pattern irregularities and rough contour of the stone. Second, influenced by the local cultural customs coming from Mayan traditions with the use of plaster on the walls. Several fundamental questions remain partially or entirely unanswered due to the insufficient material and evidence to

thoroughly compare both structures, such as drawings or historical documentation. The construction of the Los Esclavos Bridge was a significant milestone of the vault method in the region of Guatemala. This bridge acted as a tool for learning, which provided the Mayan Indigenous and the Spanish masters the opportunity exchange the knowledge of masonry bridge technology and adapt it to local needs. It is anticipated that future analysis through photogrammetry will be reported on the bridge that can reveal more secrets about the history of its construction.

PAPER #6.07

ARTS AS CATALYST: STRATEGY FOR URBAN REGENERATION - CASE OF BENESSE ART SITE: NAOSHIMA, INUJIMA & TESHIMA-

Koichiro Aitani[a]
[a] Texas A&M University, College Station, Texas, USA

ABSTRACT

"Benesse Art Site Naoshima" is the collective name for all art-related activities conducted by Benesse Holdings, Inc. and Fukutake-Foundation on the Naoshima Island and also extended to the Teshima Island in Kagawa Prefecture and the Inujima island in Okayama Prefecture. The Seto Inland Sea, known as "Japanese Mediterranean Sea" with hundreds of islands, are now became the tourist destination triggered by the combination with ART, Architecture and Nature.
In a heyday of these islands, industries brought permanent habitants, however, due to the decline of industry along with aging population, brought significant problems in there. Benesse's fundamental aim was to create engaged spaces by bringing contemporary art and architecture in resonance with the pristine nature of the Seto Inland Sea, a landscape with a rich cultural and historical fabric.
The world-renowned architect, Tadao ANDO was asked to be an advisor for establishing an "International Learning Camp", and 3 years later, commissioned the first project, Benesse House Museum, mixed-use development of hotel and museum (1992) after Benesse opened the International Camping field in 1989. As a great impact resulted from this bench mark project, Benesse accelerated its various interventions in Naoshima, as well as surrounding islands. Collaboration with Kagawa Prefecture government, they have launched the Art Triennale, since 2010, so far four Triennale has been held (1st: 2010, 2nd:2 013, 3rd: 2016, 4th:2019). In totalling with 105-108 days of this art festival, over 1million tourists have visited those islands during the event.
This paper will clarify a process of the Benesse's Strategy and its execution of interventions, impact to the neighbourhood, and summarizing a mechanism of urban regeneration chronologically, and will discuss and theorize this urban regeneration as an outcome of catalytic effect of series of Urban Interventions.

KEYWORDS

Urban Catalyst; art intervention; aging society; shrinking society; urban regeneration.

INTRODUCTION

Setouchi Art Triennale has initiated to pursue the reaeration and vitalization of the Setouchi Inland Sea and islands since 2010. Prior to this art Triennale, Benesse Holdings, Inc. and Fukutake-Foundation has been heavily involved with the regeneration of Naoshima Island particularly. "Benesse Art Site Naoshima", its fundamental aim is to create significant spaces by bringing contemporary art and architecture in resonance with the pristine nature of the Seto Inland Sea, a landscape with a rich cultural and historical fabric. Through contacts with art and nature, sceneries and inhabitants of the Seto Inland Sea region, they have been seeking to inspire visitors to reflect on the meaning of Benesse's motto - Well-Being.

The 1st Triennale was held in 2010, for a total of 105 continuous days in Takamatsu and Uno ports and on the 7 islands of Naoshima, Teshima, Megijima, Ogijima, Shodoshima, Oshima, Inujima, and from the 2nd time, 5 more islands of Shamijima, Honjima, Takamijima, Awashima and Ibukijima were added to the exhibition places (Table 1 and Figure 1). In addition to that, the Triennale periods are divided into 3 sessions; Spring, Summer, Autumn from the 2nd time, due to the high demand by the residents. The total number of participants (visitors) for the 1st Triennale resulted in over double numbers than originally anticipated. The nature of the art exhibition was to activate the declined island, where population decreases, ration of senior residents increases, decreased younger gradations, etc. Although the objectives to make a positive contribution to the local communities, administration and operation staff of the events depended on the local residents and volunteers on top of prefectural staff and Benesse Holdings, Inc. and Fukutake-Foundation. By the surprisingly large number of visitors to the islands exceeded the capacity of organization. Dividing into three sessions helped their operation and management of the visitors, and the Triennale was organized smoothly.

Table 1. Year, Days, Places, Artists, and Participants of Each Art Triennale

1. SETOUCHI TRIENNALE

1.1. Background

Over 1 million visitors from Japan and abroad came over the course of the three sessions. This demonstrated the popularity of the Triennale's unique approach, which allows visitors to experience the nature and culture of the Setouchi region and its islands through a wide array of site-specific works and projects. New art works and events were added with particular emphasis on each year's sub-themes, such as the region's connections with Asia and the world via the sea; the Setouchi Food Project; and sharing regional culture, such as lion dances and bonsai.

Not only the domestic and internal visitors, the number of foreign visitors rose dramatically as well. This was due in part to the establishment of additional international routes connecting Takamatsu Airport to other parts of the world and in part to the increase in overseas exposure with each Triennale. The number of repeaters also increased as did the length of time each visitor stayed in the area. In addition, a greater number of people visited sightseeing spots that were not part of the Triennale. The Triennale also generated many other benefits. The influx of visitors not only enlivened the islands during the Triennale but also sparked local initiatives directed at revitalization. In addition, media coverage by newspapers, television and magazines raised the reputation and increased the visibility of Kagawa prefecture as a whole.

Many local people were actively involved in making this Triennale a success by helping with the production of art works, manning the reception desks, offering food and hospitality that reflected local customs, and greeting and sending off visitors at the ports. Such efforts, which also contribute to revitalizing local communities, increased noticeably, indicating that they are becoming an established feature of the Triennale.

Figure 1. Islands for the Art Triennale Places. Source: (Kagawa Prefecture 2016)

1.2. Naoshima

Naoshima is an island town administratively part of Kagawa Prefecture, Japan located in the Seto Inland Sea. As of April 2017, the town has an estimated population of 3,117 and a density of 220 persons per km². The total area is 14.22 km². Naoshima Island is known for its many contemporary art museums. For example, the Chichu Art Museum (Figure 3: Top Left) houses a number of site-specific installations by James Turrell, Walter De Maria, and paintings by Claude Monet. Designed by world recognized architect, Tadao ANDO, it is located on one of the highest points of the island, and various exhibits and facets of the museum's buildings take advantage of its commanding view. Another contemporary museum (with hotel function, one of the early experiments in Japan) is Benesse House, also designed by ANDO. Table 2 shows the chronological interventions applied to Naoshima Island, Teshima Island and Inujima Island by Benesse Holdings, Inc. and Fukutake-Foundation in relation to the Setouchi Triennale.

The museums and beauty of the island draw many tourists, whose visits help support the local economy. However, it is Mitsubishi Materials, loosely affiliated with other Japanese companies of the Mitsubishi name, that dominates industry on the island, as Naoshima has been the site of massive refining by Mitsubishi since 1917. Benesse Art Site Naoshima, Benesse Corporation (one of the largest education companies in Japan and based in Okayama) has directed the creation and operation of the island's museums and other projects since the late 1980s. Basically, Naoshima is categorized in 3 regions, the North with Mitsubishi Materials, Central is with residential neighborhoods both traditional and modern time 2020, Universitat Politècnica de València
with two ports (Miyanoura and Honmura) for residents and visitors, and the South with National Park and Benesse's Art Site (Figure 2: Left).

Table 2. Timeline of Projects in Naoshima, Teshima, Inujima. Source: (Benesse Art Site Naoshima)

1.3. Teshima

The main attraction on Teshima is the Teshima Art Museum (Figure 3: Top Middle), one of the most intriguing contemporary artworks in Japan. Standing amongst terraced rice fields, the simple concrete structure stimulates its visitors’ senses with the play of water drops on a concrete surface. Several more artworks are scattered around the island’s three fishing villages. Most are open almost every day, especially the larger museums and outdoor installations, however some of the smaller artworks are only open on weekends and holidays.

Teshima is the region’s second largest island after Shodoshima with population of 867. A forested mountain stands in its middle, and a circular road connects its three small fishing villages. Two of the villages have ferry ports, Karato and Ieura, the latter of which is the more important. A half to a full day is needed to explore the peaceful island with its slow-paced atmosphere and rural landscape. Dining, shopping and lodging choices are limited, but slowly increasing by the effect of Art interventions such as Teshima Art Museum and Teshima Yokoo Museum (Figure 3: Bottom Middle). Without previous knowledge, visitors will not notice that Teshima once made news due to a toxic waste scandal in the 1980s in which a company illegally dumped hundreds of thousands of tons of toxic waste on the western tip of the island. Cleanup efforts were finally completed in 2017 (Figure 2: Middle).

1.4. Inujima

Inujima (literally: "dog island") is a small island off Okayama in the Seto Inland Sea that is named after a large rock resembling a sitting dog. Like nearby Naoshima Island, Inujima has become known as a site for modern art in recent years and serves as a venue of the Setouchi Triennale. Due to its small size, the peaceful island can be explored entirely on foot (Figure 2: Right).

Before turning to modern art, Inujima was mostly an industrial site. During the feudal age it produced granite blocks for castle construction, and in the early 20th century a copper refinery was supposed to bring prosperity and people to the island. However, copper prices plummeted within ten years of the refinery's opening and led to its premature closure and a drop in the island's population. The refinery was not demolished after its closure, and despite being out of business for almost a century, its ruins still characterize Inujima's landscape. Designated as a "heritage of industrial modernization", the ruins with their exposed brick walls, overgrown power plant and crumbling smokestacks can now be explored by tourists.

In 2008, the refinery ruins were converted into the Inujima Seirensho Art Museum (Figure 3: Top Right) by tastefully incorporating an art gallery into the ruins. The gallery is located mostly underground and uses local materials such as granite and discarded bricks from the refinery. Among the small number of artworks on display are an intriguing tunnel of mirrors and a tribute to the late novelist Mishima Yukio, which consists of pieces of Mishima's former residence suspended in midair.

Figure 3. Architecture and Art interventions in Naoshima (Left), Teshima (Middle). and Inujima (Right). Source: (http://benesse-artsite.jp/)

2. IMPACT AND EFFECT

2.1. Effect of the Triennale

The results of input-output analysis and hearing surveys of transportation companies and other related parties indicate that Setouchi Triennale 2010, 2013, 2016, 2019 had the effects described below.

2.1.1. Economic Ripple Effects

Based on the Ministry of Internal Affairs and Communications' 2005, 2011 input-output table and the 2005, 2011 input-output table for Kagawa produced by the prefectural government, the Takamatsu branch of the Bank of Japan and the Setouchi Triennale Executive Committee concluded that the Triennale had the following economic ripple effects (Table 3, Table 4, Table 5 and Table 6).

2.2. Ripple Effects

Economic Ripple Effects (JPY) of Setouchi Triennale 2010			
	Direct Effect (JPY)	Primary Effect (JPY)	Secondary Effect (JPY)
11.1 billion	**6.4 billion**	**2.5 billion**	**2.2 billion**

Table 3. Ripple Effects of Setouchi Triennale 2010

Economic Ripple Effects (JPY) of Setouchi Triennale 2013			
	Direct Effect (JPY)	Primary Effect (JPY)	Secondary Effect (JPY)
13.2 billion Spring: 2.7 billion Summer: 5.9 billion Autumn: 4.6 billion	**7.7 billion** Spring: 1.6 billion Summer: 3.4 billion Autumn: 2.7 billion	**2.9 billion** Spring: 600 million Summer: 1.3 billion Autumn: 1.0 billion	**2.6 billion** Spring: 500 million Summer: 1.2 billion Autumn: 900 million

Table 4. Ripple Effects of Setouchi Triennale 2013

Economic Ripple Effects (JPY) of Setouchi Triennale 2016			
	Direct Effect (JPY)	Primary Effect (JPY)	Secondary Effect (JPY)
13.9 billion Spring: 2.8 billion Summer: 5.9 billion Autumn: 5.3 billion	**8.6 billion** Spring: 1.7 billion Summer: 3.6 billion Autumn: 3.3 billion	**2.9 billion** Spring: 600 million Summer: 1.2 billion Autumn: 1.1 billion	**2.4 billion** Spring: 500 million Summer: 1 billion Autumn: 900 million

Table 5. Ripple Effects of Setouchi Triennale 2016

Economic Ripple Effects (JPY) of Setouchi Triennale 2019			
	Direct Effect (JPY)	Primary Effect (JPY)	Secondary Effect (JPY)
18.0 billion Spring: 5.2 billion Summer: 5.0 billion Autumn: 7.7 billion	**11.2 billion** Spring: 3.2 billion Summer: 3.1 billion Autumn: 4.8 billion	**3.7 billion** Spring: 1.1 billion Summer: 1.0 billion Autumn: 1.6 billion	**3.1 billion** Spring: 900 million Summer: 900 million Autumn: 1.3 billion

Table 6. Ripple Effects of Setouchi Triennale 2019

Direct Effect: The amount spent that would flow out of the prefecture, such as goods and services that must be procured externally, etc., was deducted from the amount spent by Triennale visitors within the prefecture.

Primary Effect: The increase in output for each industry within the prefecture due to the Triennale's direct effect.

Secondary Effect: The increase in output for each industry within the prefecture due to the direct and primary effects that would result in additional consumption due to increased employee earnings.

The economic ripple effect within Kagawa prefecture in 2013 amounted to 13.2 billion yen, which represents an increase of 2,100 million yen, or a percent increase of 118.9%, compared to 2010.
The economic ripple effect within Kagawa prefecture in 2016 amounted to 13.9 billion yen, which represents an increase of 700 million yen, or a percent increase of 105.3%, compared to 2013.
The economic ripple effect within Kagawa prefecture in 2019 amounted to 18.0 billion yen, which represents an increase of 4,100 million yen, or a percent increase of 129.4%, compared to 2016.

Over all, the Triennale has been proved successful and even more the degree of economical impact getting bigger.
Operation budged including 2years of preparation for each Triennale was 723 million JPY (2010), 1 billion JPY (2013), 1.27 billion JPY (2016) and 1.25 billion JPY (2019). The budget has been increased, and the period of the triennale was almost identical. The number of visitors is increased as well. Comparison of the Economic Ripple Effect over the budget is 15.3 (2010), 13.2 (2013), 10.9 (2016) and 14.4 (2019). This proves the economic impact against the investigation is very successful.

2.3. Amount Spent by Visitors

Setouchi Triennale 2016	From Outside: Overnight Stay	From Outside: Daytrip	From Kagawa: Overnight Stay	From Kagawa: Daytrip
Ratio Amount Spent/Person (JPY)	47.0% 43,699	26.0% 15,927	1.0% 33,975	26.0% 15,514

Table 7. Amount Spent by Visitors of Setouchi Triennale 2010

Setouchi Triennale 2013	From Outside: Overnight Stay	From Outside: Daytrip	From Kagawa: Overnight Stay	From Kagawa: Daytrip
Ratio Amount Spent/Person (JPY)	43.0% 41,870	23.0% 14,529	1.0% 31,762	33.0% 14,899

Table 8. Amount Spent by Visitors of Setouchi Triennale 2013

Setouchi Triennale 2016	From Outside: Overnight Stay	From Outside: Daytrip	From Kagawa: Overnight Stay	From Kagawa: Daytrip
Ratio Amount Spent/Person (JPY)	47.5% 53,127	21.4% 19,150	0.9% 31,072	30.2% 14,646

Table 9. Amount Spent by Visitors of Setouchi Triennale 2016

Setouchi Triennale 2016	From Outside: Overnight Stay	From Outside: Daytrip	From Kagawa: Overnight Stay	From Kagawa: Daytrip
Ratio Amount Spent/Person (JPY)	52.6% 67,034	18.8% 13,913	1.0% 29,281	27.6% 13,041

Table 10. Amount Spent by Visitors of Setouchi Triennale 2019

The amount spent by overseas visitors was 61,733 yen per person, accounting for 13.3% of the total in the "From Outside: Overnight Stay" category.

The classification of visitors is divided into 4 categories: From Outside - Overnight Stay (50 %), From Outside – Daytrip (22 %), From Kagawa - Overnight Stay (1 %), and From Kagawa – Daytrip (27 %). Approximately of the breakdown was relatively similar. Significance of this table is the amount spend by the outside p overnight visitors increases.

Gender	No. of People 2010	%	No. of People 2013	%	No. of People 2016	%	No. of People 2019	%
Female	7,826	68.6%	11,637	67.5%	10,297	67.2%	4,419	67.2%
Male	3,581	31.4%	5,602	32.5%	5,019	32.8%	2,387	32.8%
Total	11,407	100.0%	17,239	100.0%	15,316	100.0%	6,806	100.0%

Table 11. Number of Participants for the Questionaries' Survey by Visitors in 2010, 2013, 2016 and 2019

Setouchi Triennale	2010	2013	2016	2019
Average Days (Stay)	1.96 days	2.48 days	2.72 days	3.05 days
Average Overnights (Stay)	1.94 nights	2.00 nights	2.36 nights	2.56 nights

Table 12. Average Days and Nights spent in Islands, Survey by Visitors in 2010, 2013, 2016 and 2019

Table 11 shows the proportion of Female and Male numbers who contributed to the Questionaries' Survey in 2010, 2013, 2016 and 2019. It shows the tendency of more female visitors than male visitors, roughly 2:1 throughout of the all Triennale.
And Table 12 shows the increase of average days and nights to stay in islands.

CONCLUSION

Many local people were directly involved in the production and implementation of Setouchi Triennale 2010, 2013, 2016 and 2019. This has become the culture and developing a sense of bonding among them. Such involvement contributes to the revitalization and restoration of local communities and is becoming a firmly established feature of the Triennale.
Not only making an economical advantages and impact, each Triennale helped building the benchmarks on the islands. Those permanent facilities will generate visitors even outside of the Triennale years. Chichu Art Museum in Naoshima, Inujima Seirensho Art Museum of Inujima, Teshima Art Museum, and Teshima Yokoo Museum are the great landmarks or anchor destinations to trigger more visitors.
There are tendencies for new restaurants and local inns to accommodate tourists by converting the vacant houses. Locations are mainly in the existing neighborhoods. The mechanism of spread of renewal is still unclear, therefore, it is significant to carry on this research by finding out when and where the new shops/inns appeared in 3 Islands (Naoshima, Teshima, and Inujima). Other small islands are still lacking permanent interventions yet.
The increase of permanent residents is clarified; however, the numbers are still limited. Most obvious reason is the visitors are limited still seasonal. Therefore, to make continuous income through the year is challenging if they rely on the tourism.
Conclusion is the Benesse Holdings, Inc. and Fukutake-Foundation, and Kagawa Prefecture`s effort has been very successful to revitalize the declined islands, moreover, it makes declined islands as a world-wide destination. 30 years ago, nobody knows those islands outside of Kagawa prefecture or Shikoku Island, now the international recognition is superb. It is important to continue observe, to collect data for this impact, and find out theory behind for application to other places.

ACKNOWLEDGEMENTS

This research was sponsored by the Japan Society for the Promotion of Science with a Grants-in-Aid for Scientific Research. Also, my research was concentrated the theme of "Urban Catalyst", and my previously published book, "Urban Catalyst" from SHOKOKUSHA Publishing Co., Ltd. contributed the research approach. PAPER #6.08

SPACES AND PLACES OF CULTURE FOR THE RENEWAL OF CONTEMPORARY CITY

Antonino Margagliotta[a]
[a] Università degli Studi di Palermo, Palermo, Italy

ABSTRACT

Spaces for culture are necessary places for human and community life. Architecture gives form to this need and contributes, at the same time, to the construction and modification of the city.
In countries where architectural culture is more widespread and civic sense is linked to the qualifying experience of space, the construction of new spaces for culture (museums, libraries, etc.) - or the redevelopment of existing ones - has contributed to spreading the presence of services into the territory and has proved to be a valid opportunity (or pretext) to launch urban qualification programs (of the historicized city as well as that of recent formation). Moreover, it allowed to give quality to the public space through the modification induced in the context by the architectural project, through its ability to define formal relationships and functional correspondences, as well as significant exchanges with the existing place. In some cases, the new architectures, designed or become the strategic presence of urban transformations, have collaborated to outline (and communicate) the true identity of the city. In particular, public library, more than any other space, revealed itself to be a political-cultural communication tool: library projects have often determined initiatives and established important dynamics for the regeneration of the city (requalification of historic centres, provision of services of the suburbs, attribution of identity to the newly formed settlements). The library, a place of knowledge and encounter, of sociality and dialogue, exalts and develops transversal processes up to be a suggestive pretext for defining a program on the role of architecture and public space in the current urban scenarios.
In addition to outlining the theme in its transversal motivations and through some recent architectural solutions on the international scene, the contribution will present the results of an academic research project about the role of libraries (as representation of collective memory, invention and renewal occasion too) in the contemporary city.

KEYWORDS

Architecture; culture; city; library; project.

INTRODUCTION

The spaces and places for culture (especially libraries and museums, which are linked respectively and traditionally to the presence of books and of art) have been transformed spatially and typologically in recent decades; they have also modified specific settlement strategies, taking on precise roles in the organisation and construction of the contemporary city. Historically these architectures have been built (especially since the nineteenth century) in what we now consider the historic city, sometimes in buildings specially buit for, sometimes in pre-existing buildings of considerable historical and architectural value. The latter condition, if on the one hand it has defined the identity and prestige of many cultural institutions, on the other hand it has also determined a strong link between institution and city, even helping to clarify the image of the city itself. Many libraries, located in buildings sometimes created even

earlier to the formation and transmission of culture (convents, monasteries, seminaries, colleges) have guaranteed the permanence and continuity of the cultural institution in precise areas of the city and allowed the architecture to last, despite transformations and tampering. In this sense architecture has represented the vocation of the place and the recognition of the cultural institution. However, this condition is now sometimes assumed to be a weak and a critical point: the presence of libraries and museums inside the ancient city and in historical containers opens up some questions to be read and interpreted in the necessary relationship between the cultural structure, the architectural organism and the city, which appear to belong to internal order (since historical buildings have little inclination to change and assume the degrees of flexibility that modern cultural services require) and to external order (because of the difficult accessibility, the impossibility of expanding and acquiring new functions). At the same time, now that the city has expanded and become polycentric, architectural culture and political strategies favour the diffusion of services for culture in the vast urban area, the prediction (or implementation) of which has often proved to be an opportunity (or pretext) to launch qualification programmes both in the historicised city and in the recently formed one; it has also made it possible to confer quality on public space through the modification induced in the contexts by the architectural project and the ability of architecture to define formal relations. In some cases, the new architectures, conceived or become the strategic presence of the transformations, have collaborated to delineate (sometimes even projecting outside) the identity of the city itself with the iconicity attributed to the project.

1. LIBRARY ARCHITECTURE IN CONTEMPORARY CITY

Among spaces for culture, public library - more than any other space – has revealed itself to be a political-cultural communication tool: library projects, through presence of service for community and the role of space, have determined several urban initiatives and established dynamics for the regeneration of the city as requalification of historic centres, provision of services of the suburbs, attribution of identity to the newly formed settlements. The interest comes from the role of library, outlined in these years, which became a fundamental space of sociality and democracy that helps to overcome the individualist risk of contemporary societies tending to impoverish city of public spaces and cultural spaces. Library's role and functions transformation has been supported by several experiences made in those countries where architecture culture is consolidated and diffused while civic sense goes through public spaces as necessary qualifying agent for growth and learning. At the same time, in these contexts library represents for inhabitants a service for the community and a usually frequented place. It represents for the city an opportunity to organize public space and, sometimes, to give and identity to the existing one. Construction of new libraries and the spatial and organizational requalification of many existing structures, became an opportunity to create places for encounter and dialogue, to provide services to territories and, even, to enhance city marketing actions undertaken through *cultural operations.* Library went beyond a certain rhetoric which for century has consider it as a space – if not as a temple – for books but it can't be considered anymore exclusively connected to preservation and access to books: it is no longer a poetic "public granary" as described by Marguerite Yourcenar because the primary role of the book is now substituted by the primary role played by the user, therefore by the person that reads, or better, by all those

people that populate this space also for activities different from traditional reading; it is neither the "splendid courtyard" described by Joseph Fletcher where is possible to converse with old sages and old philosopher. To understand what a library of a contemporary city has become, it should be remembered that Temple University public library was open on 2018 in Philadelphia designed by Snøhetta to support 39,000 thousand students of the university but also to welcome (besides other traditional spaces for books storage, study and research) a variety of places for cooperative and social learning and to accommodate 5,000,000 visitors per year.

During these years, library became a perfect architecture to start and establish urban transformation dynamics: there are many contemporary experiences where the project of a library allowed to offer or to return to cities, meant as urbs (therefore as space and organisms) and as *civitas* (therefore as a community), spaces and places that historically and traditionally belongs to territory and population as right to access to cultural development and to access to cultural services. Library, though as infrastructure and as fundamental service for city and territory (as well as hospitals) it is an authentic place of urbs and civitas which accelerate urban regeneration and qualification in a physical and social sense, applying democratic principles; therefore, the public library is protagonist of city redevelopment projects, being a perfect example of participation and sharing, of freedom and creativity of each citizen.

Especially from recent architectural experiences, the role played by public libraries in contemporary cities arise as strategic presence in transformation's dynamics as important public space to freely access to information, as cultural service oriented to a polyvalent character. The library has lost its mono-functional place sacral character responsible for books preservation and to knowledge diffusion, in order to became a communication space (a centre of information and formation) and a place for community.

From the organizational and spatial point of view library transformed itself in a flexible container capable to contain multiple functions and roles, likewise necessity of user as changed following the rapid development of multimedia and digital technologies, with a destiny similar to museums: it is not a coincidence that, among cultural spaces, it goes to Piano & Rogers' Centre Pompidou in Paris the claim and implementation of a *free* space to facilitate interdisciplinary of communication tool, youth and pauperistic language which, anyway, can't stand without support of most sophisticate technology, almost like a revival Labrouste's libraries technological vocation. The Beaubourg, like a supermarket - which will be taken up again twenty years later in the Idea-stores (new concept libraries and permanent training centres designed by Adjaye Associates in the East End of London as a response to the decline of traditional library and training services) puts at the centre of the project the void for users (who see and touch everything), not necessarily attracted by the book but by the activities connected to it. As well as the *Sala Borsa* in Bologna (2001) uses the covered courtyard of an old building, in communication with the street, as the main space of a public multimedia library of general information that privileges the use of electronic resources and access to new information technologies, positioning itself as a centre of aggregation through services and the organisation of cultural events open to everyone, the city and the metropolitan area: it is the *square of culture* (Agnoli 2009) that opens the library to the city and is itself a fragment of the city. The library, in this way, becomes dynamic and "moves, driven by the interests and interventions of its users that are constantly developing and transforming" (Oechslin 2017, 29).

The library is then to be considered as a mirror reflecting the city and contemporary sociality,

at the same time a place of education and communication, "instrument of a social communication strategy [...] emerging point of a leisure management policy that involves the urban equipment and the planning of specific metropolitan areas. Around [libraries] the cultural districts are organised, through which the revitalisation of disused containers is proposed" (Irace 2001, 6-7), ancient buildings are recovered and reused, particularly in cities where the number of historical buildings and the density of the urban fabric are significant. In this vision, even libraries institutionally responsible for conservation and documentation (often located in ancient buildings) have directed their management towards overcoming the traditional model and have focused on promoting integrated cultural and social initiatives (Fig. 1). In these institutions, moreover, the enormous growth of the library heritage and of the number of users has in fact transformed the library into an urban component, a point of accumulation of the social and cultural life of the city; therefore, in any case, even historical libraries must perform more varied and complex functions than in the past and require reorganization with new architectural solutions.

2. THE PROJECT FOR NEW LIBRARIES FOR URBAN REGENERATION

Following the needs and transformations of the contemporary city, considering the role of the public library as an architecture that structures urban space, bearing in mind that the library still remains susceptible to definition and continues to offer itself for experimentation and research, the project of public libraries has often been used as a didactic theme for the students of the Course of Studies in *Building Engineering - Architecture* and in *Architecture* at the University of Palermo. The project of the public library, integrated in different urban contexts to propose services suited to the idea of the city, has for several years constituted the suggestive pretext for the definition of a programme about the role of architecture and public spaces in the contemporary city, with the ambitious intention of attributing to the projects the value of exemplariness, in the hope that the formal values of the building (and the transformations induced into the city) will generate further beauty in public and even private spaces. In any case, it proved to be an exercise in beauty and civil commitment. Within the framework of a general vision on the issues related to the library project in the contemporary city in different conditions and contexts in the didactic activity of the Courses, the project of new architectures has been privileged with the intent also to study new places of culture and meeting in the territory of modernity and in the contexts of marginality. The first experience - *A library for every city* - carried out in the academic year 2008-09 (*Course of Architecture and Architectural Composition 1* - prof. A. Margagliotta, tutor Giovanni Lumia and Ignazio Saitta) involved the whole of Sicily since small towns do not always have public places and spaces where to cultivate cultural interests and have opportunities for meeting and comparison. In small towns the library can represent an important centrality and assume the function of a multi-purpose cultural service. On this occasion almost fifty projects of small libraries are formalized for as many cities for which, in addition to spatial and figurative, functional and constructive research, the positioning and insertion in the urban landscape, the design of open spaces played a fundamental role, having taken as a starting point for the construction of the place relations between the existing system of signs, with the idea of identity and belonging (Fig. 2, Fig. 3).

In the academic year 2012-13 (*Architectural Design Laboratory 1* - prof. A. Margagliotta, tutor Sebastiano Provenzano, Ignazio Saitta and Giuseppe Scuderi) the theme was explored with the project of *new architecture*

for the municipal library system in Palermo: small neighbourhood libraries to highlight the need for new *cultural infrastructures* for a city of great size (which, among other things, was preparing that year to become the Italian Capital of Culture 2019) with the intention of strengthening the municipal library system with a *widespread* presence to be established in emblematic areas, either in the organisational strategy of the neighbourhood, in the relation to the recognisability of the place, or in order to resolve critical spatial or environmental situations. Symbolically, eight areas were identified, corresponding to the municipal districts into which the city is divided, for which each library had to express its identity and explicit its identity. Thus the library of the old town centre (which is the district where all the ancient libraries are located and would be considered already abundantly served) is planned in a highly degraded but highly suggestive area for *the multimedia library*; in the district characterised by a small port (memory of a seaside village) the library requalifies the ancient landing place and builds the *library of the sea*; in a marginal district, marked by environmental degradation, inside a disused quarry the *environment library* is planned; in the residential area, in the area belonging to a school, the programme includes the *learning library* (Fig. 4). In this way, besides proposing a realistic functional programme, the project participates in the idea of *propagation* of architecture and services into the city, so each site has been chosen with its own specificity, which the project have to highlight in relation to the logic of the settlement, the character of the place and the communities for which it is intended. In this way the library becomes a new urban centrality with the function of a multi-purpose cultural service that acts as a centre of aggregation capable of encouraging more intense and active participation by citizens in the life of the community.

In the Degree Course in Architecture in Palermo (Agrigento's headquarters) during academic year 2016-17 the students of *Laboratory 3 of Architectural Design* (prof. A. Margagliotta

- tutor Giovanni Gueli and Sandro Lo Bello) designed new spaces to enhance the existing municipal library of Agrigento with new functions and attractiveness. Strategically, the area below the railway station forecourt has been identified, which today constitutes itself an urban centrality and is close to the municipal library and other cultural institutions. Also in this case the formulation of the functional program foresees functions necessary for a library that intends to relate and identify itself with the activities of a cultural production centre. The new place had to strengthen the existing service with new attractive spaces through the quality of the architecture that for didactic and narrative reasons is developed with a possible theme (the immaterial library, the library/archive, the children's and youth library, the multicultural library, the city library, the library of sounds, the popular library, the study-library, etc.) that synthesises the cultural and social needs of the city.

3. THE DESIGN EXPERIENCE ON HISTORICAL LIBRARIES

For several years, from 2008 to 2013, the final thesis Laboratory of *Building Engineering - Architecture Degree Course* (in charge prof. A. Margagliotta) developed a study and project strategy on places and spaces for culture in the contemporary city, identifying as a privileged area of research the city of Palermo for which (in addition to museums and places for music) project proposals have been developed for the reorganization, enhancement and expansion of historical libraries. The methodological approach followed as a path:

- the study, critical analysis and redefinition of the organisational structure in relation to modern techniques and recent library economics;
- the understanding and the attribution of meaning to the spatial structure, conducted through the history of the fabrics, the survey of the architectural complexes (of which the libraries often constitute only a small part) in order to overcome, through the project, the dyscrasies and fragmentations deriving from property constraints that over time have dismembered the architectures and caused the loss of spatial unity;
- the definition of the institution's relationship with the city in order to rediscover the sense of architecture in its relationship with the urban structure, also taking the opportunity to resolve open spatial issues through the project, wounds that have never been healed, to restore quality of abandoned or degraded spaces, to restore meaning to spacial situations waiting to be defined, to build the city.
- the elaboration of a design solution on the scale of the building and the city.

The projects, starting from the analysis of critical issues, aimed at reorganising spatiality in relation to the reasons of architecture, often aiming at configuring new extensions, sometimes redefining the proprietary framework because of architectural and urban coherence, sometimes with new projects describing new potentialities and new languages to be put in dialogue with what exists. Through the projects, an attempt was made to address a cultural policy for the city that aimed to adapt the library service to contemporary standards and, at the same time, to redefine the library's presence in the city (Fig. 5, Fig. 6).

All the project proposals, therefore, include both the redefinition of the existing spaces and the hypothesis of expansion through the search for a capacity of relationship that the new must establish with the historical architecture and cultural services existing in the urban surroundings; They also intend to express the sense of a research that contains the understanding of the urban phenomenon in relation to the artefact studied and the possibility of generating spatial relations, making the single intervention an opportunity for regeneration for a portion of the city (whose extension is connected to the capacity of interference of the single artefact with the morphology and the nature of the service offered). The project of the new, under this light, is not taken as an isolated phenomenon but is inserted into urban dynamics, generating relationships, connections, paths, unifying parts that have undergone processes of separation or detachment over time. Ultimately, through study, analysis and experimentation, the works as a whole have the ambition to offer a vision for the spatial and cultural redevelopment of the city.

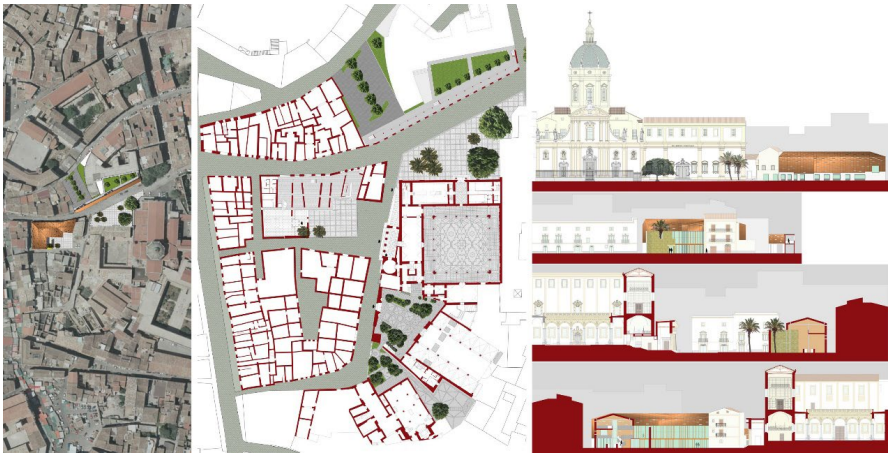

Figure 5. Reorganization of the Municipal Library of Palermo. Source: (Carmelo D'Anna, Antonio Giunta 2005)

4. CONCLUSION. EXERCISE THE COMMITMENT

Ultimately, the library requalifies the city in two ways and defines itself as a priority for the presence of users and is proposed as a place for the dissemination of knowledge, information and training, enhancing the possibility of developing cultural and social activities.

For the new libraries, which have become a symbol of urban public space, the project therefore becomes a way of rethinking urban spaces, of removing them from the increasingly rampant and pervasive commercialisation and making them places of encounter, exchange and collective action. In this vision, the public library becomes an *open territory*, a centre for reflection and knowledge sharing, the node of a network with other cultural institutions.

For the existing historical libraries, in particular, it is time to redefine the places in which they have settled, considering the condition that the contemporary city has assumed: in the face of the external turmoil, inside the library it is possible to find spaces for silence and listening (listen to others, to memory, to oneself). However, it becomes essential to adapt the spaces to the new ideological and library-related needs, offering more modern and attractive services, mitigating the austerity and rigidity of the buildings with the provision, where possible, of new expansions that coexist with the presence of the past but speak the contemporary language.

These aspects, with a view that simultaneously embraces a single building, a system of buildings and the city, are analysed through the ability of architecture to offer itself, for its relational value, to address (and try to solve) spatial and socio-cultural issues, in the ideal of an architecture that knows how to become an instrument of promotion and development. We have tried to grasp this attention and share it with young people in the didactic dimension, with the awareness that the project's didactics accord aesthetic issues to ethical ones.

However, the library cannot renounce beauty and the presence of books: the library can only be beautiful because it bears values for the

Figure 6. Reorganization of the Library of the Capuchin convent in Palermo. Source: (Giovanni Lupo 2015)

space itself and for the city itself, knowing that beauty educates and generates other beauty. This is the great responsibility of architecture. The library, then, must build on the friendly presence of the book as it is an ancient but lasting sign of culture and an expression of the dissemination and sharing of knowledge. Jaen-Claude Carriére compared the presence of books to a warm fur that warms and protects. In fact, in a library one is protected "against error, against uncertainty [...] Being surrounded by all the ideas of the world, by all feelings, all knowledge and all possible errors, offers a feeling of security and comfort. You will never be cold in your library. Here you are at least protected, at least from the dangers of ignorance" (Carrière, Eco 2009, 247).
For this reason, therefore, through the project of new libraries, as well as through the work of dissemination (exhibitions, seminars, conferences in Palermo and in the places of interest) following many of the initiatives described, we have tried to link the concept of urbs to the civitas, in order to try to influence the quality of the service, the city and, above all, the consciences of young students: urging them to pay attention to the spaces for culture, to the knowledge (and love) for libraries, to the exercise the commitment to the cities we live in. "If there is a subject that is pleasing an architect and that is capable of inflaming his commitment - Etienne-Louis Boullè seems to write about it - this is the project of a Public Library".

PAPER #6.09

THE NEW CHALLENGES FOR CONSERVATION AND MANAGEMENT OF HUWI, AHMEDABAD, INDIA

Mehrnaz Rajabi[a], Stefano Della Torre[a]
[a] DABC, Politecnico di Milano, Milan, Italy

ABSTRACT

The overall aim of this paper is to investigate the new role of Historical Underground Water Infrastructures (HUWI) as *cultural heritage*, under the contemporary environmental and climate changes. The paper's first attempt is to understand the issues related to HUWI due to the gradual loss of its original function, and furthermore, to investigate the lack of proper protection and management and usual absent of effective and feasible future plan toward sustainability and the resilience of their contexts.
In this regard, the paper also critically reviews the *P Preventive and Planned Conservation* method -a long-run strategy of integrated management of built cultural heritage- as one of the most significant and recent integrative methods of dealing with complex conditions like in Ahmedabad, India. The main challenge which this paper presents, therefore, is the engagement of the conservation, protection and management processes as an innovative method of capacity building for sustainability and resilience for both the HUWI and their local context/communities.

KEYWORDS

Cultural heritage; historical underground water infrastructures; climate and environmental change; resilience; preventive and planned conservation.

INTRODUCTION

Scarcity of water resources has always been a critical issue for most settlements in the arid and semi-arid climates throughout Central Asia, North Africa, and especially Southwest Asia. Historically people of these regions invented or slowly adopted a variety of solutions to deal with their harsh environments. Historical Underground Water Infrastructures (HUWI), which can be found throughout those territories, are among the most fascinating architectural artefacts of local production, astonishing works of engineering and hydraulics with superb formal and structural aspects. The modernization, the introduction of new industries and heavy mechanization of agricultural systems that accompanied, by accelerated population growth, have generally sought different, more ecologically damaging system of water management through deep drilling, gradually ignoring the well-planned networks of the earlier systems, which had been so carefully integrated with cities/villages, their habitats, and the hinterlands. In India, the stepwells were unique national forms of subterranean water storage systems, especially in the western states where always exists a high level of scarcity of water resources. The main functional role of stepwells was water supply, both for habitats, households, and their personal means as well as for animal watering or agricultural purposes. As the water was a crucial factor in Indian's life, the underground water buildings –as a community center and religious place– were flourished with

the best responsive interplay. In fact, stepwells were designed and constructed as a combination between utilitarian and social manifestations, where the water resource became a meeting point for social and cultural interactions, and therefore a simple act of water drawing became a ritual. With the arrival of modernization to India and the lack of water resources for industrial agriculture, the dramatic shift from traditional hydraulic system to piped system occurred and hence, almost all of those stepwells lost their original function. Nowadays, they are either drastically ignored, severely damaged and abandoned, or on the contrary their cultural image used as the center of speculation for the real-estate market. Some of them can still be found in decent condition but totally or partially disconnected from the network they once supplied from. Only a few of them have been recognized as a monument, listed as cultural heritage nationally or internationally, while almost all of these structures and their networks could be qualified as cultural heritage. Even those that remained under continual maintenance usually do not have proper management and are lacking any future plan, which could provide sustainability or resilience of their contexts –both historical and emergent ones. Although those stepwells have the potential to contribute to the touristic offerings of their regions, their current lack of conservation and their poor management, make it difficult to consider them capable of fostering either local or international tourism, or contributing to the local economy. Hence, this paper aims to explore the current conservation management issues of Indian HUWI, and to critically investigate its protection/management quality, which often lacks an effective and feasible plan toward future sustainability and resilience of its contexts. The paper questions the contemporary landscape of conservation and management of cultural heritage in India, showcasing and comparing the current conditions of two cases of Gujarat stepwells. Furthermore, as the main challenge, this paper pursues the possible new role of HUWI, especially the Indian stepwells, as *cultural heritage,* under the contemporary environmental and climate changes. The paper finally advocates the *Preventive and Planned Conservation* strategy, as one of the most significant and recent integrative methods of dealing with the complex condition of cultural heritage such as HUWI, due to its effective and comprehensive multi-disciplinary process-based approach toward the conservation of cultural heritage and its strategic long term vision.

1. HISTORICAL UNDERGROUND WATER INFRASTRUCTURES

1.1. The Indian Stepwells: the genesis of problems

During the 18th century, with the decline of the Mughal Empire in India, the door to the remarkable career of commercial enterprises of the British East India Company was opened, and empowered by its political ascendency in India until the Indian independence. And, by gradually substitution of the Indian cotton textile manufacturing with the later imported mechanized manufactured products of British mills, a new era of commercial activities and trades was started which progressively, marginalized the role of Indian merchants, as well as gradually weakened the Indian handloom weaving and spinning wheels that were “the pivots of the structure of that society” (Marx 1853). Traditionally, in response to the arid and semi-arid climate, the artificial irrigation system by canals, and water storage buildings in India was providing the basis of agriculture, in which the “prime necessity

of an economical and common use of water" required "the interference of the centralizing power of Government" (Marx 1853). Although the economic function of providing the related public works, was led by Central Government, the internal economic and social structure of the villages/small cities –the so-called village system- allowed the domestic industries -agriculture and manufacturing- and local communities, to have "their independent organization and distinct life" (Marx 1853). Nevertheless, that particular form of the social and economic structure of Indian villages and cities was, gradually, broken by the English interference in trade, land and tax policies, and by neglecting agriculture and the maintenance of water storage buildings. During the mid-19th century, thus, the consequential issues related to the mismanagement of especially water resources in India, led to the debates, that originated the *foundation of an economic critique* by Karl Mark. In his thesis, he stated that "British steam and science uprooted, over the whole surface of Hindostan, the union between agriculture and manufacturing" (Marx 1853)[1]. In parallel events, the inauguration of the railway system in India by the British Government, "opened up the door of opportunity toward the industrialization of the textile system" (Heidari Afshari and Rajabi 2016, 936), which water was the fundamental resource for that type of industry. Once, those textile mills were successfully naturalized, due to the consequential fast growth of populations around them -especially the labor class– settlement patterns of the host Indian villages/cities, were drastically transformed, in particular in the western regions such as Gujarat in which the traditionally-planned networks of the water-buildings and agricultural lands integrated well with their original habitats' needs. Furthermore, the new hydraulic engineering system –piped system– was introduced also by the British, and thus the nucleus of the "social ecology" of those water-buildings was dramatically alternated. Although "caring for wells was once a critical community responsibility and created an invisible circle around a well", after the introduction of the piped system "they [people] stopped to cleaning it" (Livingston 2002, 139). The piped system became an overcoming substitute for the traditional water structures. Starting from the late 1960s –in the post Indian independence era- the so-called *Green Revolution* credited to the new type of agriculture, to the new related technologies such as deep bore wells system and thus, to the establishment of much heavier industries. And thus for decades, India witnessed the overloaded mass water drawing. As the underground water tables dried deeper until the contemporary time, several districts in western states such as Gujarat and Rajasthan became overexploited. One can consider the *Green Revolution* as the final blow to the traditional water infrastructure. Furthermore, the big scale ambitious construction projects –nationally valued- such as the dam of Sardar Sarovar on the Narmada River in south-eastern Gujarat are the good excuse of "the government [to] ignore small restoration projects when newsworthy dams were available to them" (Livingston 2002, pp. 164-6). Those devastating events, are not unique to India, similarly lots of developing countries in the arid and semi-arid climatic zone, have faced the consequences of their late modernizations, and over scaled industrialization. The condition which more than ever seems crucial, due to the contemporary impact of climate change on the sectors such as water. In fact, the "accelerated warming has been observed in India" between 1971 and 2007, "primarily caused by an intense warming trend observed in the recent decade (1998-2007)" (Revi et al. 2015, 12),

[1] Such critiques picked up by Marxists and Indian nationalists, are still alive in political debates in India.

in which urge us reasonably to rethink the contemporary role of Indian well-rooted and culturally feasible pre-industrial water infrastructures, ignored for the last decades.

1.2. Contemporary condition of Indian stepwells; case study of Ahmedabad

Gujarat state, on the west of India, is where one can find the most distinguished HUWI, stunning stepwells, water reservoirs, and Kankarias. Geographically speaking, Gujarat has a semi-arid climate with raining monsoon and almost half a year of the dry season. In the pre-modern India, stepwells were the strategic infrastructures and eminent architectures with the capacity to store monsoon's collected water in their wells and to have it accessible during the dry season. Their strategic locations based on the geographical features of the territory, as well as, their vicinity with the main roads and settlements, were well calculated and complimented by the nature of rural India. However, as mentioned before, their condition is changed. During the last 20 years, the whole Gujarat state transformed drastically, from typical rural/hinterlands and core cities to vast urbanized territory via an exploding, eclectic and uneven urbanization process. One can clearly observe the impact of rapid urbanization in the case of Ahmedabad city, which has been, recently, converted into a mega-region of several municipalities, most of which were previously rural in 2000. That was mainly the result of the so-called *smart development* vision, which is being accelerated by the first implemented program in India, *the Integrated Mobility Plan for Greater Ahmedabad Region, 2031*; the comprehensive plan which intended to adapt both *transportation plans* and *Development Plans* together in order to, shape the future vision of the Ahmedabad and Gandhinagar region. *The Greater Ahmedabad (GA) region* envisioned to cover the developments in the area, in a span of 20 years, arriving from 8.1 million habitants in 2011 to about 12.5 million in 2031 and, increasing employment by 70% in 2031. Looking into the condition of India after independence, without a doubt, the economic reforms of the 1980s and 1990s, consequently, the *liberalization of the Indian economy* and its transition to service sector, opened up the door of opportunities to large investments of private-sectors, as well as the emergence and development of small and medium industries, which were interspersed within, the historical villages and cities such as Ahmedabad. Accordingly, under the Urban Renewal Mission the program which was launched in 2005 by the Government for the development of hundred Indian cities, the Ahmedabad city envisioned *smart city, City Development Plan Ahmedabad, 2006-2012*, and *Comprehensive Development Plan of 2021*, were initiated. All comprehensive visions, as expected, accelerated the rapid urbanization and population growth in Ahmedabad city, having 5,633,927 populations as per the Census of 2011 and becoming the sixth largest city of India. Meanwhile, the Ahmedabad district, together with Gandhinagar, possesses some of the finest examples of stepwells, all of which lack a minimum of protection/conservation, not to say, a lack of a management plan. Out of around 60 recognized stepwells in Gujarat[2], only one -Rani-Ki-Vav (the Queen's stepwell) at Patan- has been nominated and inserted into UNESCO World Heritage Sites. Those recognized stepwells are protected, by the Central Government and Archaeological Survey of India (ASI), as the monuments of *national importance*, such as Dada Harir Stepwell at Ahmedabad city and Rudabai Stepwell at Adalaj village in Gandhinagar district, or the other 45 stepwells, by the Gujarat Archaeological department. Yet, there are a lot of lesser-known stepwells in the Gujarat state that, unfortunately, are

[2] Based on the published list by the Archaeological Survey of India.

not recognized, and thus, drastically ignored, severely damaged and abandoned. (Fig. 1) Dada Harir stepwell -dated around 1499 A.D- was built with Hindu and Islamic styles. It is located in the eastern part of Ahmedabad city -near the core historic city, which by 2017 inscribed in the UNESCO World Heritage List- in the post-industrial context with several abandoned textile mills' sites, several small/medium-scale industries, and their low-income society settlements. Nowadays, the stepwell and its mosque are, to some extent, isolated and separated from their context, original programs, and social and economic structures of their contexts. Although, Dada Harir stepwell, is declared as the monument of *national importance*, in the development plan of the city, it is not provisioned as a cultural heritage site. The stepwell suffers from ignorance, not only by the state government and decision-makers but also by local people -where Hinduism entails the majority religion in the city. And thus, during the last decades, the preservation plans for the stepwell mostly were limited to the monument itself. (Fig. 2) On the other side, another declared *national importance*; Rudabai Stepwell -dated around 1499A.D, located at the historic village of Adalaj and constructed with Hindu style- currently, is one of the most famous touristic destinations on the periphery of Ahmedabad city. While, the stepwell's complex is well protected, during the last decades, the edges of its protected boundary and the surrounding areas of the historical nearby village, have been dramatically transformed. Such immediate transformations were the consequences of separate development plans based on the promotions of tourism in India initiated in 2002, followed by the states' tourism policies in 2015, and accompanied by the regional *smart development plan*. For instance, the new highway and touristic facilities nearby the stepwell, built under the assumption of beautification for the mass tourism, has been transformed the social, economic and spatial structure of the village. By consequence, the villagers are being, more than ever, separated from the stepwell, incoming tourists and any possible future programs of the under-used touristic facilities. (Fig. 3)

2. CONSERVATION, MANAGEMENT, PROTECTION IN INDIA

The Archaeological Survey of India (ASI), under the Ministry of Culture, is the prime governmental organization that is responsible for excavations, protection, conservation, and preservation of monuments and sites, already recognized as the monuments of *national importance*. While the Archaeological department inside the states conducts the preservation activities, as well as, the protection actions on the *protected monuments of the state*, the Indian National Trust for Art and Cultural Heritage (INTACH) -the only non-governmental body of professionals in India- has been involved, with identification, documentation, protection, and conservation of India's cultural, natural and intangible heritage, which are not under the jurisdiction of the ASI as well as protected heritages of the state; INTACH's Charter of 2004 -*charter for the Conservation of Unprotected Architectural Heritage and Sites in India*- has been the main document, to refer to, for the conservation of *unprotected architectural heritage and sites of India* within an institutional framework. Nonetheless, without a doubt the conservation manual of Sir John Marshall, in which the principles of the conservation was comprehensively laid down, for the first time, is still one of the primary conservation references in India; where the values of cultural heritage used not to be considered, in governmental decision makings and policies, nor inclined to be inserted in legislation and norms and similarly used to follow the old colonial-period heritage laws, constituted by focusing on the fabric of the monuments, or else, on the material-based approaches (Sharma 2019). In recent years yet, the ASI has adopted several international charters and guidelines to, better, define conservation approaches for the protected monuments (NPC – AMASR 2014). Likewise, *The National Policy for the Conservation of the Ancient Monuments,*

Archaeological Sites and Remains (NPC – AMASR) of 2014 is the first conservation policy in India for safeguarding, protecting, managing and conservation of the monuments and sites of *national importance*. The National Policy primarily dealt with the internationally recent issues such as *capacity building* and *building of partnerships with multi-disciplinary organizations and institutions, Community Participation in Conservation, Public-Private Partnership in Heritage Conservation and Management, Tourism and Visitor Management,* and *Disaster Management*. The National Policy was envisioned, in concurrence with the provisions of the *Ancient Monuments and Archaeological Sites and Remains* (amended and revalidated) Act of 2010, which, in specific, obligated the 100 meters around protected boundary of the monument as *Prohibited Area or Buffer Zone*, and further beyond the prohibition area, up to 200m in all direction, as the *Regulated Area*[3]. However, those protections designated for monuments, such as stepwells of Ahmedabad, have not been successfully implemented or, if the profit necessitates, the more powerful bodies prefer not to deliberate those further protections around heritage. On the contrary for instance, in the case of Rani-Ki-Vav, it was evident that besides all Indian heritage regulations, the international organizations had effective influence on the stepwell's protection from the disengaged development plan of the city of Patan, which was prepared and sanctioned, before inserting the stepwell at Tentative List of UNESCO, in 1998, and its inscription at UNESCO World Heritage List, in 2014. In recent years, several policies, charters, and strategies are passively deliberated by Government, ASI, and INTACH, in order to adopt more *values-based* and *people-based* approaches to conservation, management, and protection of built heritage in India, yet, practically, they have not been even-handed; as in two cases of Dada Harir and Rudabai stepwells, the missing roles of local and low-income communities in the so-called *smart development* plans were evident, and the process of economic speculation of residential extensions and *tourism development* exceeded over the conservation programs of the two monuments. At least, in the monuments of *national importance* under the protection of the Governmental bodies and the legislations which are *purpose-oriented*, one can, clearly observe that those decision makings are still based on the *top-down* attitudes and the new tendencies on the *bottom-up* approaches are not yet considered effectively. And, thus, by contemporary measures, those monuments, are not validated truthfully as *cultural heritage*; their factual authenticity and significant values, are not fully recognized by decision-makers, politicians, and developers as well as, by their local people. The actual condition on Indian conservation, critically requires a shift in attitudes, towards a *global strategy* which "needs to be carefully designed as a set of different tools (regulations, incentives, education, and dissemination of best practices...)", and "actions have to be taken at different levels, and many regulations have to be harmonized" (Della Torre 2010, 169). In India, the missing link in the regulations and the strategic plans is that they are not strategically oriented toward conservation, management, and protection of cultural heritage. That does not mean that the plans and strategies should include conservation of monuments inside their programs, but rather put the conservation of resources especially cultural heritage and its human resources, in the center of all key decisions. Involving citizens, local professionals, experts, and NGOs, should be the main orientation for the policy making for those contexts. As a result, in order to identify the contemporary role of that cultural heritage

[3] The *Prohibited Area*, where no construction is allowed, the *Regulated Area*, where any new construction will be granted permission only with the approval of the National Monument Authority and ASI.

such as stepwells, in their historical and emergent contexts, it is necessary to understand their true authenticity and to recognize them as *cultural heritage* with its most comprehensive and contemporary meaning which includes integration among different disciplines, and at various scales.

3. GLOBAL CHALLENGE FOR CONSERVATION; CLIMATE CHANGE AND CULTURAL HERITAGE POINTS OF VIEW

Taking to account that although climate change has critically affected our cultural and natural heritage sites, generally speaking, the current national and international rules and policies on climate change have not been placed in any respective plans for heritages; "Only Italy and France have included Cultural Heritage in their respective National Adaptation Plan to Climate Change" (Lefèvre 2018, 15). Moreover, cultural heritage still does not have any central role in any international Policies in relation to climate change. In rare cases like Italy, the *Italian National Strategy for Adaptation to Climate Change* referred to cultural heritage sector -by the three technical-scientific documents produced in 2014 and connected with Cultural Heritage protection will be discussed (Bonazza 2018). The ground-breaking initiative of ICOMOS Symposium on *Climate Change* in Pretoria in 2007, was one of the first to underline the significant impact of *Global Climate Change* on cultural heritage "that is often about loss and destruction as much as preservation" (ICOMOS 2008, 4). The initiative underscored "the serious local social impact from such loss" and the involvement of local communities "in establishing related priorities" (ICOMOS 2017, 18) policies and decision makings. But, the turning point was in Quebec ICOMOS Symposium in the same year, which promoted efforts to actively involve climate change concerns in cultural heritage practices. Meanwhile, by 2007, the UNESCO's efforts, on identifying the world heritage properties at risk from climate change, achieved the significant results, in a compulsory *Policy Document on the Impacts of Climate Change on World Heritage Properties,* and in a pioneering report on *Predicting and Managing the Effects of Climate Change on World Heritage* as well as a "strategy to assist States Parties… to implement appropriate management responses", in order to "protect the outstanding universal values, integrity and authenticity of the World Heritage properties from the adverse impacts of climate change" (UNESCO 2007). And thus, "Between 2007 and 2017, 154 reports on 38 World Heritage properties located in 33 States Parties were examined … in relation to climate change related impacts on Outstanding Universal Value" (WHC/18/42. COM/7, 2018). Currently, the World Heritage properties play a significant role in gathering and disseminating the impacts of Climate change, raising public awareness, and capacity building in relation to their contexts. And in similar events, freshly revised UNESCO *Strategy for Action on Climate Change* (2018-2021), -recalls the same strategy of 2008, was adopted by the UNESCO's General Conference in 2017, so as to underline the 2015 United Nation's *Paris Agreement on Climate Change*, and *the 2030 Agenda for Sustainable Development*; "an innovative and ambitious agenda that places the issue of the environment and sustainability at the center of all social and economic activities" (UNESCO 2019, 6). The strategy considers four thematic focus area for action: *Climate change education and public awareness programs and policies, Interdisciplinary Climate knowledge and scientific cooperation, Cultural diversity and cultural heritage safeguarding,* and *Inclusive social development, intercultural dialogue and ethical and gender quality principles*, for climate change mitigation and adaptation.

Developing countries such as India are also slowly picking this issue up. For instance, in 2017, the *Declaration on Heritage and Democracy* issued by ICOMOS in New Delhi identified the *Heritage* and *Democracy* as key ingredients in a *people-based approach* to *sustainable development*, as well as setting it as a relying vision for the cultural heritage societies toward climate actions. One can argue that it is natural for those countries to have consequential delay in recognizing and adopting those kinds of brand new international agreements, yet the concerning issue is that, despite all considerable international efforts during the last two decades, not only the bodies involved in cultural heritage conservation in those countries, have been inefficiently engaged in this mainstream, but also there is no significant and organized rise of cultural heritage concerns in regard to climate change alarming issues.

And that is mostly due to the absence of sensitive cultural heritage driven management system and the lack of consensus among public and governmental bodies regarding the climate change preventive and planned actions.

4. PREVENTIVE AND PLANNED CONSERVATION

The analysis of the current situation of stepwells in India detected a dramatic alternative between abandon and improper management of some cases, which should be protected, but rather suffer exploitation and commodification. This happens because the recognition as *cultural heritage* does not entail a management system focused on the multiple roles heritage can play for local development, but just on the function to foster tourism. Therefore, decision making refers more to tourism destination management models rather than to best practices in the heritage field. Actually, some practices in the heritage sector can be inspiring in dealing with HUWI problems. Some decades ago the problem has been set no longer just in terms of outstanding values, but in the frame of a wide vision of the implications of growth at the planetary scale. This was the contribution given by Giovanni Urbani (1925-1994), who actually started a research stream on conservation as the management of risks, overcoming the theoretic and radical discussions on the preventive conservation, enhancing it from the scale of the objects in the museums to the monuments and sites at territorial scale. Underscoring a shift in the whole matter, that "Cultural heritage must not be dealt with, separately from the natural environment", he prepared, accordingly, a pilot plan for the planned conservation of the cultural heritage in Umbria in 1975[4], which considered the environmental concerns in the conservation of cultural heritage that was radically different from the traditional restoration. One can observe a distinctive common background between Urbani's *Conservazione Programmata* and the parallel concept of *integrated conservation* stated by the *European Charter of the Architectural Heritage* of the Council of Europe and the Declaration of Amsterdam in 1975. By the verge of 21st century, Urbani's planned conservation was re-launched in Italy, encompassing the idea of *preventive conservation*, in concordance with the Italian development of planned conservation from 2000, especially by enforcing the *Cultural Heritage Framework Law* in 2004 which quantified the *strategy*, as a "coherent, coordinated and planned activity of study, prevention, maintenance, restoration". The statement obviously presented the paradigm shift from traditional restoration as event,

[4] Only part of the foreseen activities were implemented, thanks to the enduring commitment of the Umbria Regional Government. Urbani's initiatives were perhaps unsuccessful, because of the political issues of that time, but they had a great influence on the long run.

to conservation as process, which didn't refer anymore to single actions, but "include many more phases, tasks, and activities, like restoring, maintaining, monitoring and also, planning" (Della Torre 2010/a, 169; Della Torre 2010/b, 145) inside the process as a *whole*. And evidently, in the new method, all the phases introduced to be implemented within a long term vision, in order to achieve the maximum coherence. Urbani's claims also bridged the gap between Italian and International practices, introducing a broader understanding of the relationships of cultural objects with environment and society. Those researches in Italy eventually ended up in a vision and a management model, the *preventive and planned conservation*. One can argue, that the focus on prevention has been undoubtedly inspired by the best practices in Netherlands and Belgium, or by the problem solving approaches practiced in the UK. Indeed, the successful experiments in practice by the preventive conservation in Belgium underscored the cost-effectiveness of the approach and highlighted the well-known message of *prevention is better than cure*, and it is worthy to underscore that also these researches came to broaden their approach towards issues like community involvement and economic impact (Van Balen, Vandesande 2015; Van Balen, Vandesande 2016). The *preventive and planned conservation* has been theorized as a long-term strategy of careful planning of uses and quality, information management, regular maintenance and control of environmental factors (Della Torre 2013 and 2015). In this comprehensive vision, all actions and strategies on cultural heritage are deliberated, to be programmed, in the systematic view that they are coordinated, by the management process. As, the strategy encompasses the *planning of large scale features*, from the policies and decision makings for the optimal performance of local people, it emphasizes on being "implemented in the design of regional development projects which encompass investments on cultural heritage properties and sites" (Della Torre 2013, 123). As a matter of fact, strategically, as a new management approach dealing with built cultural heritage (Vandesande et al. 2018), in a long-term vision, endeavors to put together a top-down approach (prevention of territorial risks, such as floods, quakes, abandon…) and a bottom-up approach, i.e. every day behaviors of stakeholders, like architects, conservators and users (Della Torre 2010 and 2013). And thus, in case of successful implementation, this kind of strategy is more effective and feasible in the coherent sustainability and resilience frameworks. In the *preventive and planned conservation* method, the main targets are oriented to, involve different actors and supply chains and to give the opportunities for educational activities and training on the field, as the tactical tool for innovation and capacity building. It provides thus, the necessary condition, to the intellectual capital enhancement in the target territory. In this regard, conservation as planned process, by recalling the *culture as a unifying factor*, could have effective incentives on the improvement of local/ regional development processes, in order to empower local resources and economy. This vision is focused on the recognition of the potentialities of cultural heritage for society, economy and development, and spans from the value of precious details to the global trends related to major challenges and threats. That's why this model is promising, in order to deal with the problems detected in stepwells, which are no longer useful for everyday life in a becoming world. In overall, the capacity to provide an effective and comprehensive multi-disciplinary process-based approach toward the conservation of cultural heritage, inclusiveness of the process, and its strategic long term vision, is making the *Preventive and Planned Conservation*, one of the most appreciated methods in regard to the contemporary challenges like climate change as well as enhancing the intellectual capital of

a territory; the issue which former methods and approaches of managements and policy making in the camp of conservation, failed to address feasibly and effectively, especially in the global south and countries such as India.

CONCLUSION

The *cultural heritage* which, in the 21st century discourses, has been proved not to be anymore, "a cost to society" (*Getting cultural heritage to work for Europe* 2015, 6), but rather, a unique constructive *identity*, should always be measured as an important source of *creativity and innovation* that could encourage *education and lifetime learning*, enhance local development, and empower the local and regional economy. It is obvious that it is almost impossible to achieve these objectives, unless, the governmental bodies consider and apply the integrative type of methods for the conservation and management of cultural heritage, to guarantee their historical and contemporary social, cultural, economic and environmental values and, last but not least, to revive their true authenticity. The main challenge in this regard and, in complex contexts such as Ahmedabad -within its fast-forward development and growth- is, exactly in the systematic management of cultural heritage which, introduces and follows the rational and feasible paradigm of resilience. To put it simply, the management of cultural heritage is much different from the management of the cultural and natural destinations of tourists that insists on the cultural image or, the *Outstanding Universal Value* of cultural heritage, in order to produce the center of speculation of the real-estate market and the source of attraction for the tourists which, is far away from the contemporary definitions of sustainability. Regarding the resilient attitude toward cultural heritage, more than ever before, the need to think and act differently seems necessary; in those contexts, the overall condition of conservation debates requires to change the attitude in both public and engaging bodies. And thus, the strategic plans have to provide stability by refusing to fell in a trap of short term political positivism. The innovation has to be found, in the provision of constancy and anticipation of uncertainties rather than achieving the so-called *smart growth* objectives. The *preventive and planned conservation* as an innovative long-term management approach to cultural heritage, with the definition which was mentioned before, would be an appreciated alternative, especially regarding the contemporary challenges of climate change for cultural heritage. While in 2018, the Intergovernmental Panel on Climate Change (IPCC) projected that by 2030, global warming could reach +1.5°C, and thus, urged all to "immediately and collectively achieve a paradigm shift" (IPCC 2018), the 2019 UNESCO's report of *Changing minds not the climate* underscored that "the climate crisis is an ethical challenge". The management plans should actively pick upon "the cultural dimensions of climate action" (ICOMOS 2019, ii). And, in the contexts such as Ahmedabad, with a long history of water preservation and traditional resilience toward arid climate, the stepwells, are not just water infrastructures out of commission, or historical sites, their value as cultural heritage, are far more climatically ethnical, and culturally proactive. And thus, at least, the stepwells can act in the *preventive and planned conservation* as the strategic *identity* for the contemporary dimension of cultural resilience.

PAPER #6.10

AN INCESSANT RESEARCH EXERCISE ON THE HISTORICAL CONTEXT OF FIORENZUOLA D'ARDA CITY

Michele Ugolini[a], Rossana Gabaglio[a], Stefania Varvaro[a]
[a] Politecnico di Milano, Milan, Italy

ABSTRACT

Designing means looking at and listening to what surrounds us, it means respect for the dense layers of signs sedimented by the time that, in their continuous change, become elements that enrich the existing heritage.
Knowing the stratigraphy of a building or a context, not only in a physical sense, allows us to think about new uses, new needs and to set them up in a manner consistent with the pre-existence.
It is a matter of unveiling potential unexpressed identities to materialize them in reality and bring them out of their latent state.
When the project faces a historical built environment, the role assumption of the knowledge direction becomes particularly significant and necessary in the transforming process of a space in another way than the original one. The project interprets the role of unifying catalyst of the different disciplines necessary for the design of a new space.
Following this track, the case study of Fiorenzuola d'Arda city will be taken as a concrete laboratory in which the knowledge of history has become a guiding tool for the project.
The enhancement of the architectural context characterized by the presence of historic buildings with their internal spatiality and the open space with which they relate, also requires the inclusion of new architectural elements, both through internal interventions, and through new addictions, opening a dialogue aware between what the building was, is now, and what is becoming. A process that is not closed in itself, but that tries to investigate and value the continuous and changing relationship between the city, a part of it, and the single architectural episode with its system of relationships.
It is a profitable process that defines levels of complex relationships, enriches, presents, adds, removes, mediates, tells, briefly, plans the change, searching the appropriate form.

KEYWORDS

Architectural heritage; permanence and transformation; unveiling identity.

INTRODUCTION

The demonstrative occasion of the project methodology application to investigate and design in a systemic way, which primarily chooses to work on the existing heritage by promoting a line of sustainable development for the current city, was the collaboration program between a group of researchers from the Polytechnic of Milan and the Municipal Administration of Fiorenzuola d'Arda city.
The ambition to offer a concrete project theme and direct debate with institutional bodies and citizenship over the years has allowed us to verify new functions and activities to be included, test different structures of public spaces, highlight the possibility of connection urban alternatives, framing the focus of the investigation each time within the historical stratigraphy and re-reading the complex weave of signs and relationships that constitutes the urban fabric.

1. KNOWLEDGE AS A PREMISE TO RESPECT COMPLEXITY AND TO REKINDLE A TERRITORY TOWARDS THE PROJECT

1.1. The complexity of the territory: space and time

The territory can no longer be considered as the physical place where fragmentary monumental episodes are located, but as a complex system of architectural assets and open spaces that interact to form its structure. The widespread historical architecture is perhaps the essential component of the landscape resources that contributes to determining the historical substance of any territorial system. Recently, in addition to the interest in architectural monuments, all those tracks that constitute a concrete testimony to the material, social, political and religious life of a place and the community that inhabits it have become important: the effort result, both in terms of knowledge and design, is to consider them as part of a more complex and articulated system.

Within this ever-changing panorama, the architect interprets, builds and tells. Apparently in opposition, construction - linked to space, which uses stone to show itself - and storytelling - linked to time and word - are instead closely related to each other: in fact not all about the space is regarding to the form, and not all about time is related to the stopwatch.

Both are linked to the concept of human life (Riva 2008): that's why we can define the existing reality, be it an urban or landscape fragment, a place of living, with all the meanings and depth that derive from it. When the architect is called to know and to intervene on architectural heritage, in its several aspects, the effort has to be to interpret places not only from the physical point of view, in any case very rich of meanings and character, but also from an *anthropological* point of view: the built carries on itself the tracks of the ways of living.

Questioning ourselves also on this aspect is necessary to prefigure possible transformation scenarios able, on the one hand, of preserving the character of tradition and, at the same time, of welcoming new needs and new requests and trying to give an answer through an appropriate spatial configuration.

1.2. The knowledge between representation and vision

First of all, what do we mean by a *knowledge project?* A representation that is the language we use to describe a piece of the world. What is represented is not the reality itself, but a reconstruction chosen by the observer who, by returning it, interprets it. However, it cannot be limited to a description of the obviousness, linked to the perceptual approach, but has to become an explanation of the phenomenon investigated.

Through an inquiring gaze of complexity (material, architectural, spatial, relational...), capable of a *deep vision*, it aims to reveal the mechanisms and reasons that explain, as well as give meaning, to the evidence. It is not an almost obsessive accumulation of data and notions, although scientific, the use of these, in a conscious and transversal way, to be able to highlight the *underlying form* (Tagliagambe 1998, 20), or the system of relationships (physical but also temporal and social) between the parties.

Therefore bibliographic, documentary, and archival research become an opportunity to read and interpret the transformation processes, over time and in the matter.

Survey activity is no longer a mechanical action - taking measurements and returning them graphically - but it means investigating, researching, knowing, and understanding, to acquire awareness of the complex and articulated nature of architecture, over time and history.

Specialized investigations, which in recent decades have used increasingly advanced

equipment, are invaluable when they help to give specific answers, to validate some insights or not. The analytical data itself, the result of a specialist investigation, has a relative and limited value if not related to the complexity of the complete cognitive activity.
The constructed reality remains unchanged; knowledge can be compared, therefore, to the set of linguistic tools that we use to explain the existing, capable of giving us back the most different aspects, which are located at levels of greater or lesser depth.
The knowledge of the built city is therefore an opening in a multiplicity of interpretations that have to be respected in their plurality and become the premise for the project. Different points of view and methods of investigation from ours help us to read and understand the forms of contemporary life: they are the result of an articulated framework of complicity and differences, of contradictory and complementary elements of continuous processes of direct and induced transformation.

1.3. The project between permanence and mutation

The territory cannot be described, analyzed, and even less designed, and therefore transformed, through simplifications and reductions, but requires an approach

> that respects its inextricable complexity and the simultaneous presence of heterogeneous events and aspects, which they constitute a network of relationships that is gradually expanding to always include horizons larger and to compose a dust of possibilities that aggregate and disintegrate starting from portions the existing one (Tagliagambe 2005).

How can these design experiences, so specific in terms of context, architectural, material, spatial and temporal characteristics, become opportunities for research?

The question is once again related to the ability to "ask the right questions, choose the right tests and find the right conclusions" (Tagliagambe 1998, 18). The challenge consists in the ability to investigate a specific *object* (an urban or landscape fragment) through its peculiarities and, at the same time, be able to abstract its aspects capable of interpreting some more general questions. Following this, we can test, through the project, a response to conservation and transformation requests.
A project thought not as the only possible but as, "the possible alternatives seen from reality" (Tagliagambe 1998, 34): it's an active and dynamic balance between the rights of the *sense of reality* and the reasons for the *sense of possibility*. We can speak of *ontological planning* (Winograd, Flores 1987), which looks back on the tradition that has formed us, but also towards the transformations that have not yet taken place; it's can only grow on the existing, and starting from it to imagine possible scenarios.
So what is the challenge that increasingly becomes a necessity? Being able, through the project, to define a balance between the ability to innovate and build new meanings and, at the same time, the capability to subordinate these changes to the preservation of a specific identity, which we can define dynamic (Tagliagambe 1998, 5-6).
The essential condition of any authentic and effective design activity is therefore the *ability to feel* and see reality not as something complete and defined forever, but as a process in continuous evolution.

2. THE CATALYST AND UNIFYING ROLE OF THE ARCHITECTURE PROJECT

The assumption of direction role of knowledge and disciplines required in designing a space in a many and different ways from the original one, becomes particularly significant. The architectural project has the catalytic and

unifying role of this articulated process of knowledge.

> Modification, belonging, context, identity, specificity, are a group of words that seem to presuppose a pre-existing reality to be preserved by transforming it, passing on its memory with the traces in turn founded on the basis of the previous traces, a reality that appears in the physical form of a geography whose cognitive cult and interpretation of which provide the backbone of the project (Gregotti 1991).

The project therefore, as a meaningful synthesis of knowledge and interpretation of the existing heritage, has the responsibility to convey the contributions of all the disciplines that, today more than ever, contribute to better define a space. Without this cultural direction in the project the technicalities, the norms, the laws, the functionality prevail and the space, with the load of meaning expectations, is lost.

2.1. A recent experience of territorial government policy in Emilia Romagna region

Promoting a culture that recognizes the complexity of the urban fabric in which it is called to operate, underlines the relational values between the parties and recognizes and confirms the importance of regeneration actions, discouraging new land use, therefore becomes the foundation of each territorial policy that wants to propose itself as sustainable. The city today should push appropriate development policies "to enhance the productive, cultural and relational potential within the growing levels of systemic interconnection" (Losasso 2015).
Based on the in-depth knowledge of the historical building at various scales, the territorial, the urban and the architectural one and defining a systemic framework of all potential that the existing carries with it, has certainly represented a constant with which to measure oneself by those who work in the area, but also an essential challenge of not always easy promotion.
In this sense, the policies of the Emilia Romagna region, one of the most advanced regions of Italy together with Lombardy, are interesting to understand how administrative and political support is a necessary condition for extensive and shared action.
Since the early 1990s, the Urban Redevelopment Programs introduced by the Regional Law have been promoted and funded n. 19/98 "Rules on Urban Redevelopment". These planning actions have anticipated for a large part the contents contained in the "Urban Regeneration" call issued subsequently by the Emilia Romagna Region, without however putting into place a real systemic planning. On the other hand, they contributed to increasing the sensitivity and institutional development of a more structured and complex programming. It is in fact in 2018 that the aforementioned regional call for funding is being promoted which it intends to represent:

> a policy in support of the reuse and adaptation of public and private heritage with targeted, long-lasting and sustainable planning, of obtaining a widespread urban, territorial, socio-economic and environmental quality that is a response to phenomena of spatial and environmental degradation combined with functional decline and poor social cohesion, divestments of activities and improper spatial uses, congestion and settlement disorder, as well as the safety and efficiency of the diffuse heritage, the requalification of marginal spaces with precise attention to the reduction of the consumption of soil. [1]

It is clear the desire to attribute to the planning action the possibility and the ability to transform not only physically and functionally parts of cities. The goal is to finance a strategy for urban quality with a view to a "revitalization

[1] From the regional call Urban Rigeneration, Regione Emilia Romagna, 2018.

of the cities of Emilia-Romagna", as it is written in the call.
The *widespread* term with which the demand for regeneration is characterized by identifying the relationship between urban spaces, buildings and structures to be redeveloped, business plans and management programs as the foundation. In summary, it is an invitation to a systemic reading of the space, be it public or private, whether open or inside a building envelope in close relationship with the life of its inhabitants. In search of what De Carli called "primary space", that complex of relationships that "above all and par excellence in architecture" constitutes "an act of qualification and an authentic attribution or donation of meaning" (De Carli 1982, 362).
Widespread also demonstrates the need to emphasize a cross-scale feature, from the municipal or supra-municipal dimension to the size of the neighborhood, square, building, with the specific request to reason by systems, never in a reducing manner. The single intervention takes on value if inserted in a broad regeneration program that involves a complexity of factors and has positive and lasting effects over the years. [2]

2.2. Fiorenzuola d'Arda

Fiorenzuola d'Arda is a small town of just over 15,000 inhabitants, located along the historical roman Via Emilia, on one of the main motorway axes that connect Milan to Bologna, in the province of Piacenza.
The historic urban fabric of Fiorenzuola is characterized by an older nucleus enclosed within a contiguous quadrilateral of the Via Emilia in which Piazza Fratelli Molinari takes a place as the core of the city with the Collegiata, San Fiorenzo Church and the peculiar bell tower detached from the church.

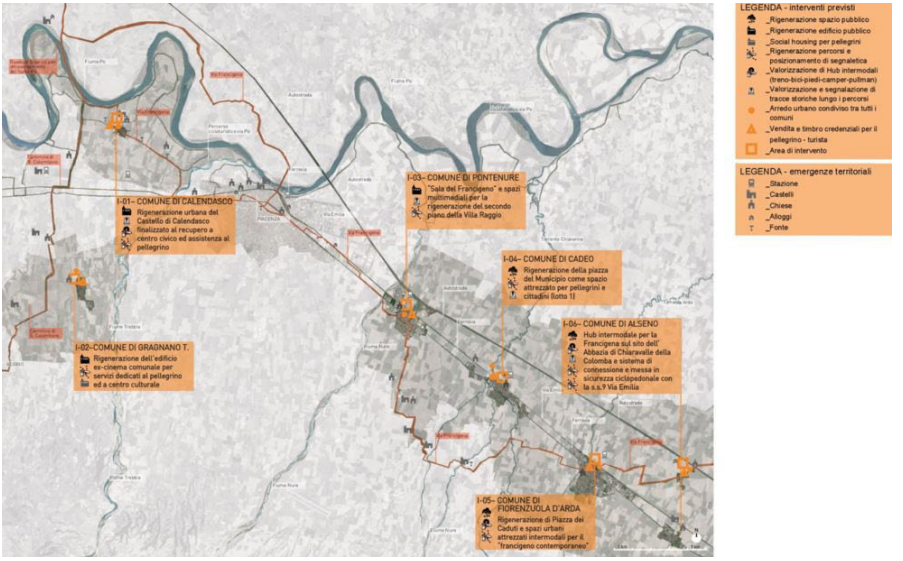

Figure 1. The Via Francigena as a territorial systemic project: the six municipalities involved whose single projects are included in a broad vision regeneration strategy are highlighted. Source: (Vito Redaelli 2018)

[2] The text of the call refers to the absence of a state-level strategy and explicitly adopts some of the principles introduced by the European Union through the Leipzig Charter of 2007 and the Toledo Declaration of 2010 (assuming the integration of policies and sustainability environment as fundamental factors for the attractiveness and competitiveness of cities) and the objectives of the European Agenda for sustainable development.

This original nucleus is in turn inserted in a first historical rectangular shape expansion that extends itself longitudinally following via Emilia, enclosed within the Roman walls on whose route the ring road of the city has been set. Blocked by the railway track, in the second post-war period, urban growth occurred mostly in the south, strongly unbalancing the city towards the hill.
An articulated road network, set on a matrix of roads parallel and perpendicular to the Via Emilia, design the historic area of Fiorenzuola; except for some streets, all road axes are quite narrow.
Instead, there are numerous spaces with a square vocation, urban value and green spaces with relational value. It is not interesting here to go into the specifics of each design solution but to illustrate the principles that generated the project experiences which are described below.

2.3. The Via Francigena as an opportunity for a linear cross-scale connection

The case study of the city of Fiorenzuola d'Arda represents an example of good practice for having participated in the aforementioned regional tender and for taking part in a grouping of six municipalities that proposed the enhancement of a territorial system and historical connection such as the via Francigena (Fig. 1). Also called via Romea, it is the set of historical routes that in the Middle Ages brought pilgrims from Canterbury to the Holy Land passing through Rome, it has united and historically and physically unites the urban agglomerations intercepted by it and, in the specific case, it is assumed the significant connector role of all the projects that each municipality has identified.
Starting from the planning policies developed after the publication of the 2000 European Landscape Convention, the landscape is

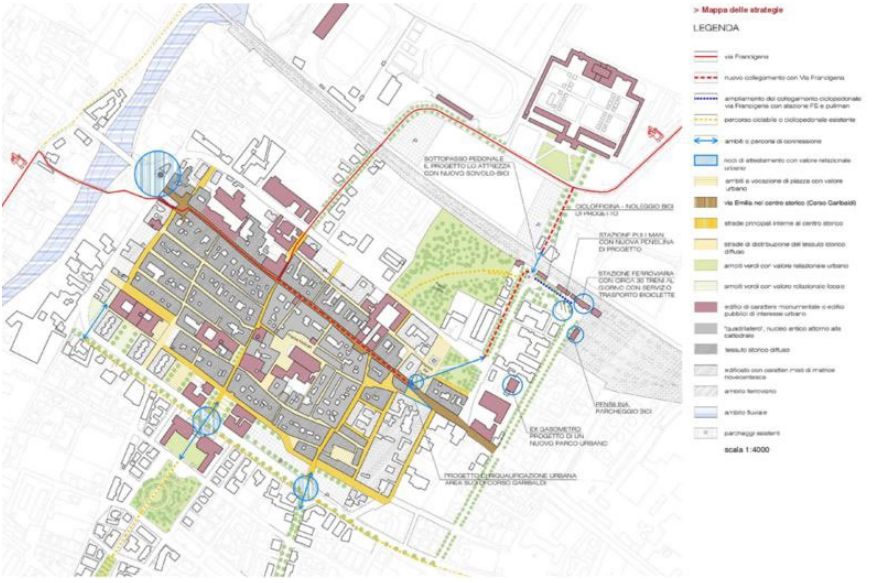

Figure 2. Map of strategies relating to Fiorenzuola d'Arda: all urban regeneration interventions are identified along the urban stretch of via Francigena. Source: (Ugolini, Varvaro 2018)

assumed among the programmatic aspects of the government of the territory.

> The Via Francigena must be structured as one of the axes of the European slow mobility network, in the idea that the corridors are not only fast mobility, but also slow mobility green ways. (...) We agree with the fact that the landscape must, in turn, be considered as one of the values of sustainability (Bettini, Marotta, Tosi 2011).

The landscape of the Via Francigena near Fiorenzuola d'Arda is particularly interesting because it touches an alternation of spaces still open in the countryside and heavily urbanized and infrastructured spaces. There are numerous architectural beauties, among which we can find the Cistercian Abbey of Chiaravalle della Colomba, near the town of Fiorenzuola, which animate the horizontal landscape of the low Emilian plain.
A strategic map is thus outlined which aims to highlight the great potential in the areas directly or indirectly linked to the Via Francigena. Specifically, in relation to Fiorenzuola d'Arda, the railway underpass is redefined as the access point of the Francigena in Fiorenzuola and the bus station, the public space in front of the railway station are redeveloped, providing them with a cycle workshop, the boulevard connecting the station and the Via Emilia is also improved. The intervention aims to enhance intermodality, as an indispensable sustainable choice identified in the broader project of strengthening and upgrading the Francigena route.
Specific occasions have been identified graphically in a dot, usually the expression of a need on the hand of the public administration, by means of a crosshatch it has been identified the area actually involved in the project actions.
It is then proposed, as it emerges from the strategic map (Fig. 2), the definition of a new urban park on the reclaimed area of the former gasometer and the redevelopment of a sequence of open spaces now disqualified and episodic, disconnected from each other, among which piazza dei Caduti takes a place. The project of the square is part of an urban design which, from via Emilia, involves the whole space in front of and behind the war memorial and leads, crossing the public garden, along the large tree-lined pedestrian and cycle path of Fratelli Cairoli boulervard, towards the railway station, the most important of the six municipalities participating in the call.
The nineteenth-century Lucca Park is also involved in this strategy, now in total abandonment, providing for its restoration and proposing it as an alternative connection between the station and the historic center.
The whole project presents via Francigena as a complex territorial system which, knots other systems at the scale of the single municipality which, in turn, strategically insert potential and critical issues to be solved. The necessary knowledge of history and its signs

Figure 3. Behind the actual town hall

Figure 4. Don Bosco school

Figure 5. Former town hall.

passes, therefore, through a dimension of cross-scale project, which, as can be seen from the actions put in place at Fiorenzuola, makes individual projects meaningful and collects the regional political invitation to structure long period topics.

2.4. Redefining the boundary between the historic center and the new expansion in Fiorenzuola d'Arda

Through the project, there have been some occasions to rethink the areas between the new urban expansion and the historic center. The request to qualify the open space behind the current town hall created the opportunity to identify and reconfigure the system of spaces overlooking the ring road that follows the Roman city walls (Fig. 3); the request for new public services within the Don Bosco school complex suggested the need to restore the city thistle to the south and to study the urban connection and the relationship between the built outside and inside the walls, pushing the sequence of spaces and urban park beyond the building (Fig. 4); the request to first place a library, then a health home inside the former town hall overlooking the axis of via Emilia has allowed us to redefine an entire urban quadrant, giving shape to the incongruous and residual open spaces, the result of planning sectorial and approximate past (Fig. 5).
The knowledge of the urban historical evolution (Fig. 6, 7, 8) together with a desire to record the complexity of the issues put in place by any changes in the status quo, has allowed us to identify spheres of influence extended to the single occasion of intervention and therefore to work on parts of the city, where open spaces take on a strategic relational role. The interpretative maps, not only historical but also investigating the architectural and urban form, the dimensions and the altimetry of the built and the ground, the green spaces, the ways of use, the critical points and, the strengths, are developed together to the design suggestions in a relationship of mutual feed.
We try to record the opportunity not to respond to the specific need with an optimal design response, but with a response that makes a reflection and obliges us to a scale and multidisciplinary discussion.

CONCLUSION

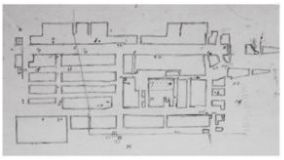
The awareness that *the urban project is structured as a dialogue with the existing, its modification and the constitution of an existing future* (Gregotti, 1993), brings with it the need to articulate that process of context historical knowledge and critical analysis that becomes a project. The analytical approach, already in the identification of the themes, structures the guidelines for a contextual reading from which the project originates. This is the teaching that comes from the work of Giancarlo De Carlo.

> Considering the environment, the city, the neighborhoods, the house not only and solely as artifacts, but rather to consider them as phenomena that make up the human experience. (De Carlo, Sichirollo, 1992)

Opposing functionalism with a reading of the use of space as *experience in all its meanings: practical, contemplative, symbolic (...)* and, proposing participation as an operational tool for drawing up plans for the city of Urbino.

> Beginning to 'know' one realizes almost at first sight, how the landscape of Urbino is rich in events, variations, subtleties, which intersect and stratify to generate a multiplicity of situations that are already memorable or can become one (...) (De Carlo, 1994)

We welcome the invitation not to give up on the interpretation of the complex nature of the urban fabric and to take it as a value, to arrive at diversification of the project capable

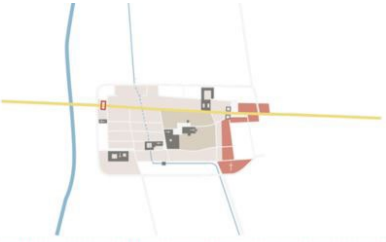


Gli isolati si spingono al di là dei confini degli assi di costruzione principali, tra cui la storica via Emilia. La città si espande a nord dell'asse storico e viene completata l'edificazione dei lotti gotici, disposti parallelamente e perpendicolarmente al castrum romano. Sono ancora ben visibili i caselli, posti alle estremità della via Emilia.

1790

Figure 6. 1790, interpretative map: the city expands beyond the historical axis of the via Emilia (yellow line) and the construction of the Gothic lots is completed, the ancient toll booths at the ends of the via Emilia remain clearly visible. Source: (Ugolini, Gabaglio, Master degree studio Politecnico di Milano 2012-13)

Verso la fine del 1800 l'espansione della città si estende oltre il casello ad est della via Emilia, andando a tangere e ad oltrepassare le mura del castrum romano. Compare il cimitero all'interno delle mura e viene interrato un tratto del canale che attraversa la città parallelo al fiume Arda.



1850

Figure 7. 1850, interpretative map: the expansion of the city extends beyond the walls of the Roman castrum, the cemetery appears within the walls and a section of the canal that crossed the city is buried, parallel to the Arda river. Source: (Ugolini, Gabaglio, Master degree studio Politecnico di Milano 2012-13)

A metà del 1900 si registra una forte espansione a macchia d'olio della città, che rimane però al di sotto del tracciato ferroviario, costruito intorno al 1870, che rappresenta tutt'ora un elemento di forte disconnessione urbana. L'espansione della zona industriale si concentra nella fascia compresa tra l'asse della via Emilia e l'asse ferroviario. Scompaiono le porte della città e l'antico sedime delle mura romane lascia spazio alla nuova circonvallazione esterna della città.

1968

Figure 8. 1968, interpretative map: in the mid-1900s there was a strong expansion which remains in the south of the railway track built in 1870, which still represents an element of strong urban disconnection. The expansion of the industrial area is concentrated in the area between the via Emilia and the railway. The city gates disappear and the ancient site of the Roman walls leaves the floor for the city's new external traffic road. Source: (Ugolini, Gabaglio, Master degree studio Politecnico di Milano 2012-13)

of grasping the richness of the stratification of history understood as vital human experience. The design experiments that have been briefly described concerning the city of Fiorenzuola d'Arda tell of the importance of facing a project never in a closed way. Whether it is a building or whether it is an open space, a street or, a square, a project is needed that, in its functions and material form, chooses the open path of relationship, dialogue, and systemic thinking never partial. In this sense and even more so in historical construction, working on the ground assumes a strategic role because it can be entrusted to it the task of establishing significant relationships between the parties.

In recent past, that of the eighties, where the non-consumption of land was already widely promoted, at least in the cultural debate, and parts of the city recovery and regeneration ware encouraged, Secchi invited to this reflection:

> (...) shift our attention: from the building to the ground, to the surface between the buildings and which cannot be denied or reduced to pure technical space. The opportunity to deal with it, the moment in which to deal with it is certainly this when the pressure for the construction of a huge amount of houses in addition to the existing ones has become perhaps lesser and, instead the pressure for the modification of the existing is strong. I maintain that it is not a matter of thinking only of modifying the use of what already exists or of replacing it with new architectures, of filling the parts of unfinished cities, but today it is also the time, if not above all, of planning the soil in a way not trivial, reductive, technical and inarticulate (Secchi 1986).

PAPER #6.11

URBAN DESIGN STRATEGIES FOR A PROBLEMATIC, SOUTHERN MID-SIZE AMERICAN CITY

Thomas C. Sammons[a]
[a] University of Louisiana at Lafayette, Lafayette, Louisiana

ABSTRACT

Lafayette, Louisiana, is a mid-size southern city with a population of 240,000. This city thrived during the latter part of the 20th century from its oil driven economy and the university, thus making it a regional, economic center. Typical of most American cities of this size which experienced staggering and unchecked growth during this time period, Lafayette now possesses a fragmented core and blighted, traditional neighborhoods. For the past decade, the city has struggled to regenerate its urban core and traditional neighborhoods, but redevelopment efforts have been stymied by political, economic and poor policy planning decisions. The city suffers an assortment of reconstruction issues including; multiple commercial centers, inadequate zoning policies, dysfunctional planning, private property rights, favored suburban development and an anemic public transportation system.

The Community Design Workshop (CDW), a graduate studio within the School of Architecture and Design at the University of Louisiana at Lafayette, has worked with the city for the past 23 years on developing urban design strategies and economic tactics for the city's renewal. Two case studies proposed policy changes and urban design planning strategies to redevelop the city's urban core. The end goal for both projects was to renovate the single-story neighborhoods into a thriving multi- level, mixed-use redevelopment.

The recent economic downturn combined with a low tax base and a shifting political climate created an environment that has impeded the city's urban core reconstruction efforts. Possessing a clear understanding of these factors while being linked to viable urban tactics for combating these issues at a policy level along with formal and economic strategies, is the foundation of the two projects and the CDW.

INTRODUCTION

Lafayette, Louisiana is a regional hub servicing the southwestern area of the state. The Community Design Workshop (CDW), a graduate studio in the School of Architecture and Design at the University of Louisiana at Lafayette, has been working with the City of Lafayette to provide both urban strategies and economic tactics for redevelopment of the city's urban core. Two projects emerged from the graduate studios that helped identify some of the barriers and possibilities for redevelopment. The first project, Freetown, a neighborhood whose name is derived from the area where free African Americans lived and worked, is currently occupied by students and faculty, and includes a mix of commercial and industry. The CDW produced urban proposals on how to redevelop this neighborhood into a multi-story development. The second neighborhood, the Oil Center, sits adjacent to the University of Louisiana at Lafayette. This area was developed for the newly emerging oil industry in the late 50s and 60s. It housed geologists, engineers, land men and wildcatters, as well as some commercial properties and a hospital. The development of this area again was a single story, single program. The CDW made proposals and wrote an urban code to redevelop the Oil Center district into mixed-use office and housing. The City of Lafayette

recently completed its comprehensive plan which lays out strategies for large buy in collaboration from neighborhoods, businesses, and public officials. The challenge for this city and the comprehensive plan is to overcome the multitude of barriers that exist within a mid-size American city.

Figure 1. Image showing French long lots. Source: (CDW – Original to Author)

1. ORIGINS OF URBAN FORM

Lafayette, Louisiana's morphology is impacted by the French long lot. A French long lot is a special land structure that exists within Southwest Louisiana along the Mississippi River Valley (Figure 1). This agrarian structure allowed French colonists access to the river for the transport and movement of goods. Partitioning the land in this manner provided main routes to the interior and created a long, thin land organization. The long-lot system divides large land acreages into long narrow strips. Each long lot had a narrow frontage on the river only 5 to 8 arpents wide but extended as much as 40 to 60 arpents deep. Cities along the Vermilion River and the Bayou Teche are organized according to this morphological structure which impacts the urban form. This urban form facilitates travel perpendicular to the bayou but becomes problematic when traveling parallel to the river. Contemporary road systems are required to cross these individual land boundaries. Jean Mouton laid out the French long lots in 1821, and the city's original 20 block position is far inland and aligned on the North-South Axis or the national grid. (Figure 2). Lafayette's early development and expansion was forced within the existing organization to the French long lots. "In the beginning, most businesses were located near the church or the courthouse or between the two. Lee Avenue later cut diagonally across the southeastern part of the map, and the cross streets and lot lines were reoriented to that axis…After the railroad tracks were laid northeast of town, streets in new additions were laid out to run parallel or perpendicular

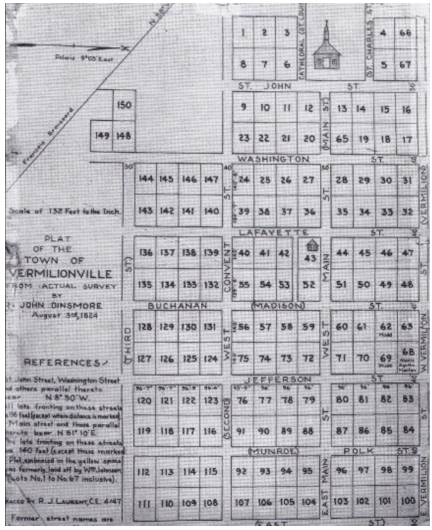

Figure 2. map showing Lafayette original 20 block position. Source: (Keisel, 2007)

to the tracks" (Kiesel 2007, 12). Lafayette's success also contributed to Mouton securing the parish church and then establishing Lafayette as the parish seat of Lafayette Parish. In 1887, the urban form was impacted by the southern intercontinental railroads which came through the City of Lafayette. The railroad forced an economic-driven shift to the city grid (Figure 3). The city's grid shift toward the railroad is an effect of landowners developing around the infrastructure. The railroad provided a corridor to connect industry to bring resources beyond the Mississippi River. Another bearing on the urban development happened in the late 19th century when the University of Louisiana at Lafayette was sought by several cities of the area, but the City of Lafayette instituted a tax to buy the land and then donated it to the state for the establishment of the University. Since the first graduating class in 1904, the University has continued to operate as an economic engine for this area. "Higher education came to Lafayette in 1900 when the Board of Trustees decided to locate Southwestern Louisiana Industrial Institute there. The Girard family gave 25 acres of land, local citizens pledged $8000 in cash, and the parish passed a two-mill property tax to support the school. Local banks offered loans totaling $10,000 against the proceeds of the tax, so the school could begin work immediately" (Kiesel 2007, 39).

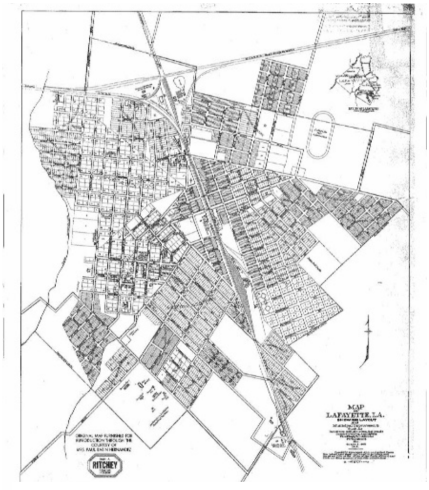

Figure 3. 1912 Map of Lafayette, LA. Source: (Dismukes, 1972)

2. SUBURBANIZATION OF A CITY

Many issues contribute to the suburbanization of Lafayette. Beginning in the 1950s through the 1970s, the United States experienced a post-war population boom. Government supported the country's infrastructure with roads, water, sewer, and electricity, thus helping to expand the American city's periphery. Lafayette was no exception. Office parks, suburbs and the American strip became common place to suburban development.

Another restriction to Lafayette's urban growth was the facilitation of the automobile. The Federal- Aid Highway Act of 1956 passed by Congress and initiated by Eisenhower, created a network of interconnected roads across the country. These main arteries led to negative consequences that penetrated the urban core of cities. The interstate emerged in Lafayette in the late sixties and I-10 was completed across the Atchafalaya Basin during the mid-1970s. The interstate shifted the economic activities to the suburban fringe. The interstate and highways became economic engines that expanded the development of cities away from the urban core. This displacement affected Louisiana cities and began the organization and emergence of suburban neighborhoods. Single-family homes encase the surrounding areas of Lafayette's urban core. "Within the overall scope of the ranch house type, an evolutionary pattern of development is evident. Primarily, both the size and complexity of the floor plan layouts increase. In fact, the house type evolves through three rather distinct phases from modest basic ranch type, on its way to the

sprawling, highly articulated ranch rambler" (Rowe 1991, 73). These subdivisions create entire communities where family incomes and demographics are almost completely similar. Suburban neighborhoods separate residential and commercial development, thus depriving the walking access for daily needs. These subdivisions mostly consist of single-family homes placed within a field of green landscape, garages that replace porches, and roads conforming to a hierarchy. Dead-end roads feed into residential streets that lead into the large collector roads to current shopping malls and strip malls hidden behind large parking lots.

Johnston Street is a major artery running through the heart of Lafayette (Figure 4). It began as a modest country highway then grew to become today's five-lane state highway. It links a series of important landmarks in Lafayette: the University of Louisiana at Lafayette campus, the Cajundome, and commercial districts along the street, including the Acadiana Mall. It is also the spine for thoroughfares that branch out to many other places throughout the city. This major artery exhibits the characteristics of most American commercial strips. With a series of object-oriented architecture placed in a field of parking lots, landscape is either miniaturized or pushed to the margins of the development while the architecture becomes a flat generic response to the automobile. Big box stores, malls, gas stations, car salons, and fast food restaurants, with a collage of signage, produced a typical suburban development that occurs throughout the United States. Acting as a connector to many important buildings and activities, Johnston Street has created extreme congestion which is one of the major problems with the existing condition. In addition, this major thoroughfare lacks a presence as a connector for a community that has a unique history and a rich and vibrant culture.

Figure 4. Johnston Street Lafayette, LA.

3. BARRIERS

The barriers to redevelopment in a mid-size American city are numerous but can be categorized into physical, bureaucratic, policy, economic, and political. The physical barriers to redevelopment can be seen in the city's urban form. This urban form was generated by the land division of the French long lots. This land pattern is useful in an agrarian economy with transportation on the river, but with established neighborhoods and developed road networks, this land pattern is problematic. The vision for this early town was somewhat limited with the original design of 1821 with just 20 blocks and limited space for right of way for roads and streets. Additionally, the lot sizes were average 40 feet by 80 feet making it difficult for contemporary redevelopment. These modest lot sizes can be seen in the 1912 plan for the City of Lafayette (Figure 3). From a bureaucratic point of view, until recently, the city was being regulated by an outdated zoning code based on suburban principles. Pyramidal zoning separates land use, institutes setbacks from the street and produces oversized parking requirements that eat up valuable land and hinder a more compact building model. The Lafayette Consolidated Government Zoning Ordinance states setbacks for the general business zoning district are, "Front- 20 feet; Side- for detached dwellings, 5 feet per side; Rear- for dwellings, 10 feet; Where lots are created

adjacent to or abutting a substandard public right-of-way, a building setback line shall be placed at a distance from the public right-of-way equal to the sum of one half of the right-of-way deficit and the zoning setback for the applicable zoning district." (Lafayette Consolidated Government 2012, 69) The setback policy which is suburban in nature excludes any mixed-use or urban buildings fronting on the public right-of-way such as sidewalks or public spaces. Administratively, the city's planning department organized its code enforcement based on the suburbanmodel. The traffic department deals with road planning and its development. The two departments rarely converse with each other and traditionally defend their turf.

With its newly completed comprehensive plan, Lafayette instituted a Unified Development Code. (Figure 5). This code replaced the old zoning ordinances and has been in place for the last fifty years. Progress has been made, particularly in the downtown, where the code is following a form-based three-dimensional model. Two new construction projects have adhered to this new code. Unfortunately, the newly elected Mayor-President has formed a task force to reopen the UDC and remove critical urban development codes in order to expedite development. "There's a regulatory aspect to this and an implementation from the administration that we need to learn how we can better serve developers, how to better serve business… Guillory said". (Welty 2020)

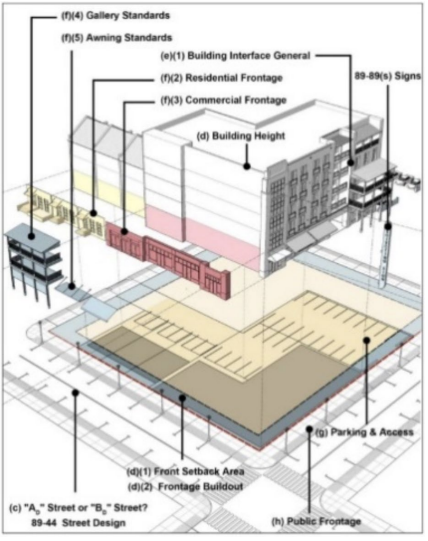

Figure 5. Unified Development Code. Source: (Lafayette Consolidated Government, 2019)

The city's most recent outgoing elected officials implemented Taxing Incremental Financing Districts (TIF). A TIF is a taxing district that has the ability to levy taxes in a designated area with approval from the State Legislature. These districts are monitored by an independent board. The tax monies can be implemented for infrastructure improvements such as electrical, roadways, sidewalks and even streetscape improvements The new Mayor-President is opposed to the economic development districts. "I want our city and parish to be known as business friendly, low tax jurisdictions that are more inviting to visitors who want to stay here and shop here," he wrote. "These taxing districts do the opposite." (Taylor 2019). This administration could stop this badly needed policy to help redevelop Lafayette's urban core.

At a state level, Louisiana has no mechanism to assemble a series of properties for urban redevelopment. Governor Kathleen Blanco's administration passed legislation that favored strong property rights over redevelopment. Political pressure applied to the city council comes from developers that do not have the skill set to build multifamily housing in an urban context and continue to only build three-bedroom family housing. The barriers for the redevelopment of Lafayette's urban core are numerous and wide ranging from physical to political. Unless some of these barriers can be overcome, urban redevelopment will be delayed and will follow the anemic pace of the last 20 years.

4. POSSIBILITIES

The City of Lafayette and the surrounding region has always enjoyed a history of creative and energetic involvement for Lafayette's redevelopment. The Chamber of Commerce and other civic groups have been hyperactive in the city's interests. These groups have been instrumental in procuring and supporting the comprehensive design. This civic process that the community has been engaged in has brought a new optimism to the city. The process is encouraging more development in the urban core and establishing an urban code. It also has been publicly discussed to reorganize the departments of planning and code revision into one streamlined department. The hope is that the plan will set some priorities for the redevelopment of the city's urban core. The University also has completed its own Master Plan for redevelopment of its campus. What is optimistic is that the University's Master Plan and the city's Comprehensive Plan are proceeding forward with an unprecedented, cooperative dialogue between the two, whereas before they acted as an independent agency making plans in isolation. The best example of this is the recent sale of the horse farm and land swap that benefited both parties for the development of a new passive park in the middle of the city. Opportunities exist to operate a hybrid condition of suburban-urban landscape in this American mid-size city. This American urban landscape is, at best, a difficult entity to read and comprehend that may be attributed to the collision of two very different city types that make up the urban condition. This condition is composed of the traditional city, and its post-industrial counterpart, the suburban city. Each has its own reading, its own properties and elements. The traditional city, with its layers of history, contains highly distinctive urban elements perceptible in its containable spaces, grids or fields, block structure, and commercial core, even if they have been fragmented by 20th century development. These elements produce a clear datum whereby one is capable of reading the city's fabric. It is within this backdrop of hybrid urban form, political and bureaucratic barriers and current economic and policy opportunities that the Community Design Workshop (CDW) has operated in Lafayette and the region in the last twenty-three years.

5. THE COMMUNITY DESIGN WORKSHOP

The School of Architecture and Design provides expertise in urban design, planning, landscape design, architecture, housing, and preservation. The Community Design Workshop (CDW), located in the School of Architecture and Design at the University of Louisiana at Lafayette has been involved with small town projects that promoted the revival of their downtown areas and neighborhoods along with large infrastructure designs for interstate highways and major arterials for Municipalities and the State of Louisiana Department of Transportation and Development. The CDW was engaged in restoration projects for small towns following Hurricanes Katrina and Rita devastation. Additionally, the CDW has completed multiple

Figure 6. Aerial of the Oil Center. Source: (CDW – Original to Author)

projects for the University of Louisiana at Lafayette. In all CDW projects, the team, which is comprised of students and faculty, propose the design, develop the construction documents and become involved with supervising the building construction The purpose of the CDW is to function as an outreach Institute to the community for urban design and provide architecture students an opportunity to gain practical experience with real world design problems.

6. TWO PROJECTS

Two projects that illustrate redevelopment possibilities are the Freetown neighborhood and Oil Center district. Freetown is an original Lafayette subdivision formerly called the Mouton Addition. Prior to the Civil War, many freed slaves settled in this subdivision, along with a heterogeneous mixture of lower- and middle-class Caucasians. Over the years Freetown, as it became known, served as a melting pot of various cultures including African, Cajun, Lebanese and Middle Eastern, Greek, Spanish and Irish. Freetown residents came together and developed their neighborhood into a strong community. Traditionally, this area has been home to university professors and their families. The other study area, referred to as the Oil Center, was developed by Maurice Heymann beginning in the 1950s through the 1970s and provided valuable office space for southwest Louisiana's emerging oil industry. (Figure 6). Originally established as a Lafayette office park, today the Oil Center is a suburban city model surrounded by housing. "The importance of the Oil Center extends beyond the oil business. The Oil Center has become a city-within-a-city, containing professional offices, retail shops, a shopping center, banks, brokerage firms, a medical clinic, florist shop, gift shops, drug stores, art galleries, and post office" (Guaranty Bank and Trust Company 1980, 78). This condition has restrained the Oil Center's horizontal expansion and has forced a more urban vertical redevelopment. The CDW hosted a series of charrettes with stakeholders for both projects where precedents of successful urban districts and neighborhoods with diverse programming were introduced. The fabric of these example urban districts called for mixed-use building typologies which allowed these districts to be more vibrant and compact. The CDW analyzed these precedents and synthesized them with the stakeholder concerns and the context of the existing districts' conditions. The CDW made impressive strides in building consensus and generating momentum amongst stakeholders and the general public regarding the redevelopment for both of these districts.

7. FREETOWN

7.1. Urban Design

Freetown's physical position between the university and the downtown has created a great need for redevelopment. Programs that would bring life to this district are a denser mixed-use fabric of housing and commercial supported by additional infrastructure of parking, pedestrian walkways, and landscape. The overall proposed plan was divided into three phases. Phase One proposed the development of four blocks at the intersection of Jefferson and McKinley Streets. Within these four blocks, a grocery store would be placed to occupy an existing building with a parking garage to extend over the roof. On the smaller block adjacent to the park, the existing industrial buildings remain but include new construction, mainly housing, and would reflect surrounding typologies. The final block proposed new construction to reflect the typologies of old warehouses and include housing, commercial, offices, and restaurants. The parking for this block would be consolidated to the block's core

thus keeping the urban edge while creating a dense street presence. Phases Two and Three continue down Jefferson Street to the downtown area and McKinley Street to the university. The redevelopment included two to three story buildings with housing, commercial, and parking. Two green spaces are strategically placed within the neighborhood offering different amenities.

Other CDW proposals presented an opportunity to connect both the University and downtown Lafayette and with the redevelopment of McKinley Street, that connection could be formed. The intersection of McKinley Jefferson Streets would become the primary node with the establishment of McKinley Park. and commercial shops on the opposite side of Jefferson Street along McKinley Street. In order to accommodate parking, three parking structures were proposed. These structures were internalized on their respective blocks and surrounded by mixed-use buildings in order to keep an active urban street front thus providing sufficient public parking for the majority of the development. The park consists of commercial and mixed-use developments surrounding a large, public green space. The northeast end of the park is home to a culturally rich development, programmed with an open farmer's market, restaurant, classrooms for culinary arts, music venue, theater, and art galleries. The other mixed-use developments incorporate cafes and retail shops that act as an extension of the park through outdoor seating. (Figure 7).

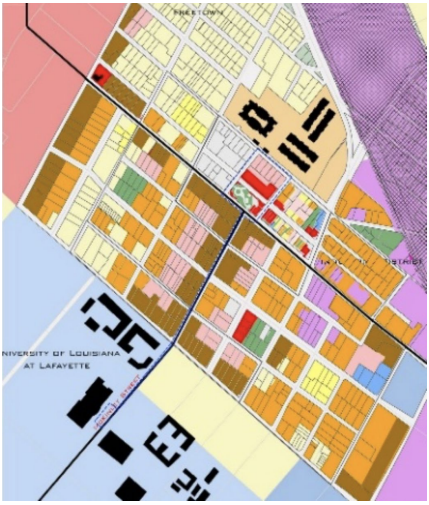

Figure 7. Mixed use growth down McKinley Street
Source: (CDW – Original to Author)

7.2. Architecture

Many of the proposals for the Freetown neighborhood took on a more urban quality along the prominent Jefferson and McKinley Streets. The architecture was kept small scale allowing it to relate to the existing neighborhood (Figure 8). The site strategy pushes itself to the sidewalk edge with parking in the back of the building. This maintains the urban edge and keeps the sidewalk activated. Along the ground floor and adjacent to the sidewalk, the building footprint carves out space for interaction with the street. These mixed-use buildings animate the street with public space for outdoor dining. Apartments are designed for the upper floors with terraces for the restaurants and the apartments. Parking was organized to the back of the buildings or tucked underneath while still being screened from the street.

Figure 8. Corner of Gen Mouton and McKinley Street.
Source: (CDW – Original to Author)

7.3. Streetscape

In order to redevelop McKinley Street and the surrounding neighborhood, a plan was generated to connect the University of Louisiana at Lafayette and downtown Lafayette through the McKinley Street Corridor. An option to create a pedestrian promenade along McKinley Street was available. Multiple schemes produced a variety of options within the promenade's plan. In urban environments perception of the street is important. In the pedestrian promenade, traffic would be diverted to peripheral streets, creating a bike path in the center bordered by landscape. Sidewalks were widened to allow for outdoor seating while balconies create an arcade for shade. The corner of McKinley and Jefferson Streets would be home to a children's playground. The overall design was a joint effort between neighboring property owners, the Lafayette Consolidated Government, and the University of Louisiana at Lafayette.

7.4. Urban Design

The urban design strategy for the Oil Center Office Park was not only to transform the overwhelming majority of its single-story/ single-use structures into mixed-use low to mid-rise buildings, but to also reverse the primacy of the automobile over the pedestrian by creating a greener and walkable community. The urban plan was forced to take into consideration that a significant public transportation system will not come into existence in the City of Lafayette and therefore, automobile access and parking would maintain its influence in all aspects of programming. The challenge of maintaining automobile access and parking, while giving primacy to the pedestrian, was further compounded by the relatively small city block sizes and the area's high groundwater table. The main parking strategy that would allow the density of the Oil Center to expand from single story to low and mid-rise buildings would focus on the creation of parking decks

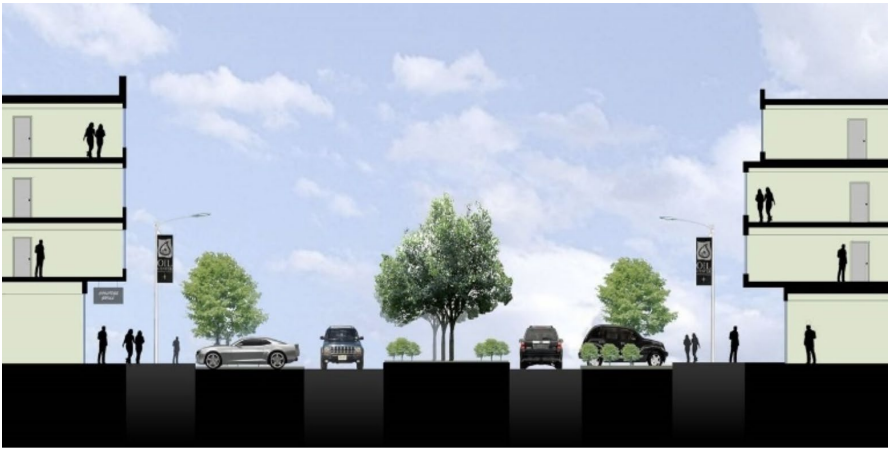

Figure 9. Coolidge Blvd Proposed Section
Source: (CDW – Original to Author)

embedded into the center of the urban blocks where each development or building would screen parking from the street and pedestrians. Additionally, a shared parking strategy for mixed-use buildings was integrated into the overall master plan. In order to capitalize on the proven value of diversified programming in the use of urban districts, the master plan offered urban buildings with commercial and/or retail space on the street level, office space on the floors above, and to be capped with residential space on the top floors.

The pedestrian urban space between the building skin and curb edge is energized by generous sidewalks and positioning the urban buildings' edge close to allow for increased commercial development on the lower floors (Figure 9). To incorporate more green space into the redevelopment, four types of green spaces were included in the master plan: urban parks, streetscapes, linear parks and a river walk. The existing boulevard landscape was redeveloped into tree-lined boulevards and streets, and the secondary streets include landscaping at the corners of the blocks. The planned extension of the existing thoroughfare to the river incorporates a linear park along the street edge, and urban parks are incorporated into the block structure in the districts. This system of parks included additional landscaping, urban furniture, lighting and benches throughout.

7.5. Urban Code

The second task facing the CDW studio was to create an urban code for the Oil Center. For mixed-use urbanism development to exist there must be a mechanism to change a suburban environment into a more vertical and compact urban environment. The CDW was able to introduce preliminary code requirements which were then tested and expanded with the CDW projects. (Figure 10). Best practices and test cases were identified and discussed at the charrettes and public meetings. Strategies for developing an urban-suburban hybrid code were chosen for the city's extreme suburban development and its dependency on the automobile. Many model codes were documented, analyzed, studied and compared including the urban code for City Place in Dallas, Texas, Transit Oriented Development Code in Austin, Texas, Buckhead Village District in Atlanta, Georgia, and the Louisiana Overlay District. Best practices and code analysis reviewed height restrictions, setbacks, floor-area ratios, parking, programming efficiencies, and proximity slopes. The projects revealed the strengths and weaknesses of the developing code. The hybrid codes strengthened and defined public space such as streets and squares. Requirements for parking placement and reduction in automobile spaces linked to programmatic and transportation needs were varied. Analysis for best practices and core elements were synthesized and reorganized to the new Overlay District. The code provided bonuses for pedestrian environments such as landscaping, bike racks, paving, public spaces, LEED certification and parking garages. These bonuses would permit a higher floor-area ratio than was otherwise allowed.

Figure 9. Coolidge Blvd Proposed Section. Source: (CDW – Original to Author)

7.6. Implementation Strategies

Public meetings and charrettes explored the issues of implementation strategies. All strategies involved developing an urban code utilizing urban design, architectural standards and economic development. Historically, the CDW has studied implementation techniques in the form of TIFs, Business Incentive Developments and Overlay Districts. A TIF District is a planning tool that supplies economic incentives to the developer and builder in redeveloping urban districts. TIF District monies can be used for a variety of infrastructure needs: roads, streetscapes, parking garages and even construction costs for new buildings.

A financial framework makes the development of a hybrid suburban-urban condition possible. Taking cues from cities such as Dallas and Lafayette itself, the Oil Center's code threads residential architecture into the existing fabric and procures success through economic stimulation. The concept of a multi-use environment dense with purpose and activity can be realized through the merger of commercial, residential, medical and other types of usage. This reinvestment in streetscape, utilities, land acquisition, parking garages and new buildings will directly enhance this area's living environment.

CONCLUSION

Lafayette, Louisiana is indeed facing challenges and barriers to the redevelopment of its urban core. The city is at a pinnacle point within their history. There is optimism that many of these barriers will be mitigated by the adopted comprehensive plan. Discussions have addressed the reorganization of the planning and transportation departments to become more streamlined and updated with a contemporary code. The other great strength for the city of Lafayette is that the creative class has been instrumental in a public discussion of a true urban form and traditional neighborhoods. Of course, support from

the University and the Community Design Workshop facilitates a public discussion on architecture that identifies opportunities within the city and advances urban design principles. The CDW goals have always been to engage the public in its design process, how student learning benefits both the student and the public, and the development of the design.

PAPER #6.12

GREEN BOOK IN ARIZONA: INTERSECTING URBAN HISTORY, HERITAGE, AND PLANNING

Clare Robinson[a], Arlie Adkins[a]
[a] University of Arizona, Tucson, Arizona

ABSTRACT

The Negro Motorist Green Book published between 1936 and 1964 steered middle-class African American travelers toward businesses that would serve them during racial segregation. Although few of the businesses listed in the *Green Book* are extant in Arizona, the neighborhoods that once hosted businesses evidenced alternate experiences of travel in a state well-known for its tourism. Many of these historical conditions remain un-researched by urban historians and architects. This paper integrates methods in architectural history, planning, and preservation practice to describe and analyze the material and social characteristics of the neighborhoods in Arizona's two largest cities, Tucson and Phoenix. The paper uses archival material, fire insurance maps, aerial photography, and census data to examine Black tourism and argues that multi-faceted and intersecting material, economic, and social conditions combined to create segregated ethnic environments that have largely been erased physically or through processes of displacement and gentrification. The study reveals that the neighborhoods home to Green Book businesses were materially poor at mid-century, built inexpensively of wood or unfired adobe, yet they also contained vibrant social and economic institutions, such as Chinese grocery stores, Mexican churches, schools, and clubs. Thus, as motels, tourist homes, and restaurants opened doors to Africa American travelers, these travelers synthesized contrasting experiences: the stereotypical images of mid-century automobile tourism and cowboy culture; modern interstate highways; and the diverse material and social realities of the urban environments in which Black travelers were most welcome. Remaining portions of the neighborhoods are now gentrified, housing affluent residents or mainstream economic and civic institutions and activities. This study of Arizona's urban Green Book neighborhoods thus illuminates the past ethnic and racial mixture of neighborhoods; the understudied outcomes of urban renewal and gentrification; and issues pertinent to the preservation of neighborhoods that have undergone significant social and economic transformation.

KEYWORDS

Urban renewal; historic preservation; African American travel.

INTRODUCTION

The Negro Motorist Green Book, created by the New York City postal worker Victor Green, was a travel guide for African Americans in the United States. Although published for nearly three decades under different names with special editions about air and international travel, the purpose and format of the book remained unchanged: businesses listed by state and city helped Black Americans travel with greater ease during the final decades of legalized racial segregation and discrimination. What appeared in *The Green Book* came recommended by travelers, select companies, and US institutions and with careful editorial oversight (*The Negro*

Motorist Green Book 1940, 4). Thus, by printing only a few paid advertisements and listing Black-friendly businesses by state and city, *The Green Book* not only steered African American travelers toward welcoming hotels, restaurants, and services, but also represented first-hand knowledge of local places. With information garnered by travelers navigating less familiar social and material environments, *The Green Book* provided a service as it evidenced the racial conditions of cities during the mid-twentieth century.

Scholarship concerning *The Green Book* examines the travel guide itself alongside Black migration and tourism in the United States (Taylor 2020; Kennedy 2013; Hall 2015). These studies consider North America as a whole, or emphasize the South, where racial segregation was most visible. Other studies analyze urban renewal's impact on cities, giving attention to the ethnic, poor, and segregated neighborhoods of metropolitan areas after World War II. Although numerous, few of these studies focus on the Southwestern states (Fairbanks 2014; Otero 2010). This paper builds upon extant scholarship by zooming into a single state and two of its cities to analyze the location of *Green Book* businesses; ethnic and racial neighborhoods; transportation routes; and the issues pertinent to urban renewal, gentrification, and the preservation of neighborhoods that have undergone significant social and economic transformation.

Arizona and the cities of Phoenix and Tucson present unique historical circumstances relevant to contemporary preservation practices and planning. Once part of New Spain and Mexico, the history of the territory and state includes Native American settlements, Spanish colonization, and modern economic expansion through ranching, mining, railroad, and road. Moreover, the state's landscape of mountains, canyons, forests, deserts, and seasonal rivers, and the harsh climate framed the experience of Arizona's diverse population, which according to the 1940 tour book, *Arizona: A State Guide*, hovered at 50% Hispanic in Tucson and 10% in Phoenix, with whites, Blacks and other races comprising the rest.[1] The vast, rugged landscape, climate, population growth, and diversity of the state amounted to a unique set attributes that differed from many other US areas. Thus as motels, tourist homes (similar to bed and breakfasts), and restaurants appeared in *The Green Book*, African American travelers in Arizona would have synthesized contrasting experiences: modern national highways; cowboy culture; Mexican food; Native American and Spanish Colonial architecture; racial discrimination; and the diverse material and social realities of Arizona's towns and cities. In other words, the complexity of Arizona's racial, ethnic and political past, and experiences of racial discrimination in the US, challenge straightforward examination of tourism, ethnic neighborhoods, and urban renewal.

1. METHODS OF RESEARCH AND ANALYSIS

This paper integrates methods in architectural and urban history with contemporary planning and preservation practices to describe and analyze the material and social characteristics of the neighborhoods with *Green Book* listings in Arizona's largest cities Tucson and Phoenix. First, the research used various archival sources, including all Arizona businesses listed in every edition of *The Negro Motorist Green Book,* Sanborn fire insurance maps of Phoenix and Tucson released in 1948 and 1949, historic aerial photography, state highways and railroad lines extant in 1940,

[1] Writers' Program of the Work Projects Administration in the State of Arizona. *Arizona, a State Guide.* American Guide Series. New York: Hastings House, 1940, pp218, 254 describes the racial and ethnic makeup of Arizona by city. Elsewhere this source states one third of the state's population was Native American and Mexican (p6).

Home Owners Loan Corporation (HOLC) home security maps (i.e., redline maps) and urban renewal districts from the mid-twentieth century. Additionally, census data from 1960 through the present contributed to the context of each city. Then, archival material was combined in GIS to spatialize Black tourism in Phoenix and Tucson. Next, neighborhoods with numerous businesses in Phoenix and Tucson were documented and described using photographs of historic properties, Sanborn fire insurance maps, and windshield surveys of extant buildings. Finally, these documents were analyzed spatially and materially for social, racial, and economic conditions.

2. GREEN BOOK NEIGHBORHOODS

Touring the United States and Arizona in the 1940s required knowledge and planning, especially if you were Black (Monahan 2016). *The Green Book* was first published just a decade after the Federal Aid Highway Act, signed into law by Calvin Coolidge, required a system or numbered highways. These paved US Routes crisscrossed Arizona and connected small and large cities, including Yuma, Phoenix, Flagstaff, the Grand Canyon, Prescott, Tucson, Bisbee and Douglas. These routes also served as important transportation links for what is now referred to as the "second great migration," which saw an exodus of 1.5 million African Americans from the South to industrial centers in the Midwest and Northeast as well as to western cities including Phoenix, Los Angeles, San Diego, San Francisco, and Oakland (Price-Spratlen, 2008; Tiagi, 2015). Other established transportation routes included rail and bus routes as well air travel in Phoenix, Tucson, and Douglas. With great distances between cities and settlements, standard tour books of Arizona recommended travelers carry water, gasoline, and layers of clothing to prepare for the long stretches of highway without services and for the daily temperature swings.[2] The open road, however, was not egalitarian (Seiler, 2006). Knowledge of local Green Book businesses helped Black travelers avoid discrimination and violence (Bottone, 2020).

Multiple highways linked numerous cities with *Green Book* businesses, but the most listings appeared in Tucson and Phoenix and situated on or near US Route 80. This route connected Arizona to southern California and New Mexico, and led travelers through the various landscapes of Southern Arizona. The neighborhoods with *Green Book* businesses were spaces of social, architectural, and urban encounters. According to Sanborn maps, the urban neighborhoods were materially poor, built inexpensively of wood or unfired adobe, yet they also contained vibrant social and economic institutions, such as Chinese grocery stores, Mexican churches, schools, and clubs. These various social and economic conditions contributed to the separation of ethnic neighborhoods in each city, but more important here were the characteristics of the neighborhoods and the physical and social environments traveling African Americans faced, which differed somewhat between Phoenix and Tucson.

2.1. Phoenix

Of the forty-eight businesses listed between 1939 and 1964, *Green Book* businesses in Phoenix resided in one of three areas. Most were located east of downtown on either Jefferson or Washington Streets in the city's historic African American neighborhood south of US Route 80 and north of the rail yard. The first listings in this neighborhood included two restaurants, two service stations, one tourist home, four motels, and a beauty parlor. After World War II, eighteen new businesses

[2] For travel guides, see the Writers' Program of the Work Projects Administration in the State of Arizona. *Arizona, a State Guide.* American Guide Series. Garbutt Company, 1913. Browne, J. Ross. *A Tour through Arizona*. 1864-1864.

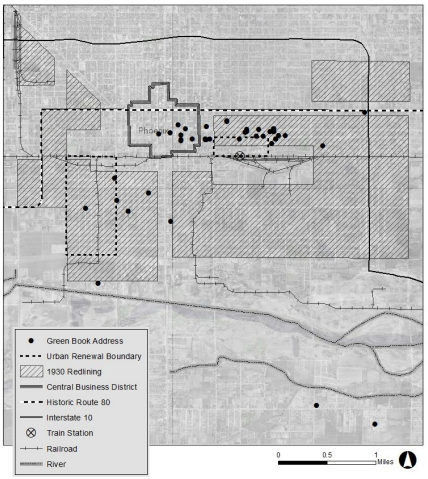

Figure 1. Phoenix Green Book businesses mapped with aerial imagery, historic Route 80, Interstate 10, railroad lines and train station. (Source: data compiled in GIS by Author 1+2 and RA1)

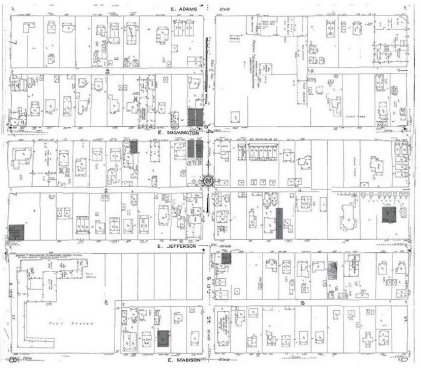

Figure 2. Select Green Book businesses in Phoenix on Jefferson and Washington Streets visualized on Sanborn maps. (Source: Sanborn, Author1, RA1)

appeared in *The Green Book*, increasing the number of restaurants and tourist homes. Although some businesses moved and disappeared from the travel book, the spatial patterns of Green Book businesses in Phoenix remained clustered together to form a clear pattern of African American tourism in Phoenix (Figure 1).

Arizona's 1940 state guide describes areas of the historic Black (and Mexican) neighborhood as the "shack town" of Phoenix, but Sanborn maps evidence a diverse working-class neighborhood (*Arizona: a State Guide* 1940, 218). Within four blocks, travelers could find a service station, a motel, numerous restaurants, and a beauty parlor as well as a Mexican Church, a Black Church, the Urban League, and the Booker T. Washington Elementary school (Figure 2). The institutions and commercial enterprises illustrated established architecture for social and economic activities and a mixture of African American and Mexican residents. Travelers to these areas would have found patterns of urban development set on a grid, with storefronts generally facing the street and built to the street's edge and dwellings set back from the street and sidewalk. Moreover, tourist homes and motels typically had an older dwelling near the street and a row of small dwellings near the alley. These street-scale urban patterns and the neighborhoods hosting businesses friendly toward African Americans suggest a breadth and diversity of economic activities in central Phoenix that would change by the late 1960s, in part through processes of urban renewal.

2.2. Tucson

In Tucson, *Green Book* businesses resided in one of three neighborhoods. The first businesses to appear, however, were located in either the historic African American neighborhood now called Dunbar Springs, which was north of downtown and the railroad line, or El Barrio Libre, a neighborhood immediately south of downtown now called The Barrio. Later listings for motels were located further south on the Benson Highway, also known as US Route 80. At a glance, the Tucson businesses presented to Green Book

travelers between 1939 and 1964 amounted to only two restaurants, three tourist homes, one service station, and three motels. In any given year, only a few businesses appeared in the book, meaning that the businesses either came and went or opened later. Although few in number, the businesses evidenced a pattern of African American tourism in Tucson in three distinct neighborhoods over time (Figure 3).

Platted at the beginning of the twentieth century, Dunbar Springs presented travelers an established neighborhood that by 1948 was peppered with African-American churches, Chinese grocery stores, service stations, and schools. Two tourist homes, for example, operated within walking distance of six established churches and several corner stores. Nearby stood a gas station and many automobile repair services. The diversity of uses amounted to a diversity of architectural style, building materials, and urban conditions. Set on a grid, bungalows made wood of wood and built on stone foundations, stood back from the street. Other dwellings made of adobe stood at the edges of streets or alleys to suggest well-defined public right-of-ways. Corner stores met the sidewalk and defined intersections. Taken together, the neighborhood presented a tight-knit urban neighborhood with local businesses, churches, and accommodations to both locals and visitors.

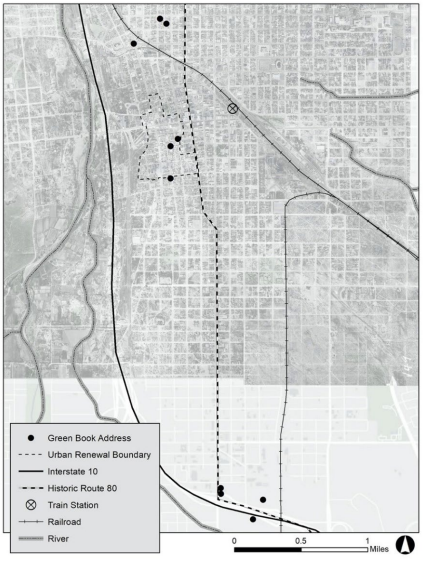

Figure 3. Tucson's Green Book businesses mapped with aerial imagery, historic Route 80, Interstate 10, railroad lines, train station and mid-twentieth century urban renewal boundaries. (Source: data compiled in GIS by Author1+2, RA2 and RA!)

An area just south of downtown Tucson, referred to locally as the Bario or La Calle, was the center of Mexican Tucson (Otero, 2010). But during the mid-twentieth century it also housed many Chinese and Black residents. Tour books suggested the Church of San Augustin, and the Temple of Music and Art, the Carnegie Library, and Amory Park as nearby tourist attractions (*Arizona: a State Guide 1940,* 259). Travelers utilizing *The Green Book* would find the Criterion Rooms one half block from Meyer Street, the main business corridor of the neighborhood where two *Green Book* restaurants and numerous other stores stood. Unlike Dunbar Springs, structures in the neighborhood were almost exclusively made of adobe and followed the urban patterns of Mexico and New Spain, with some likely dating to Tucson's pre-Gadsen Purchase history as a Mexican settlement. The thick exterior walls of buildings defined property lines, hid private courtyards, and formed a well-defined public right-of-way (Otero, 2010). With the neighborhood's urban density, dirt streets, and adobe architecture, mid-century Anglo residents of Tucson viewed the area as a poor ethnic enclave, which similar to many such areas in other cities in the US, soon fell victim to the forces of urban renewal during the 1960s and 1970s (Gomez-Novy 2003; Otero 2010).

Unlike these older parts of Tucson, the third area of Tucson that housed a number of motels listed in the Green Book represented the era of modern automobile travel. Sited adjacent to the highway, accommodations offered parking spaces, air-conditioned rooms with direct access to the outside, and a common garden or pool area. These *Green Book* motels mirrored the mid-century motor court, which by the mid-twentieth century was a national typology (Jakle and Sculle, 2011). All three of Tucson's *Green Book* motels stood on route 80 south of town near the postwar suburbs populated by a significant number of Tucson's African Americans residents (US Census, 1960). Despite their standard, modern convenience, the Green Book motels south of Tucson contrasted with the dozens of motels clustered along the celebrated and better preserved Miracle Mile (Clinco, 2017). None of the accommodations found along the Miracle Mile were ever listed in the Green Book.

Important to Tucson's history was how the pattern of African American *Green Book* businesses changed over time. The earliest *Green Book* editions listed a single tourist home and a gas station in Dunbar Springs, as well as two restaurants and the Criterion Rooms in the Barrio. In later editions, the businesses listed in the Barrio disappeared to be replaced by another tourist home in Dunbar Springs and three motels south of town. The shift evidenced urban, economic, and social factors, and the tastes of Black travelers reporting back to Victor Green. The Criterion Rooms, for example, stood near "Gay Alley," a street known for prostitution. The more reputable Veterans of Foreign Wars building was nearby, but Black travelers may have found the conditions of the Criterion Rooms distasteful, particularly if veterans were familiar with the Mountain View Black Officers Club at Fort Huachuca. Moreover, the motels south of town presented travelers options for modern, standard, and convenient automobile tourism.

3. URBAN RENEWAL AND GENTRIFICATION

Green Book locations in Tucson and Phoenix were in neighborhoods that have largely been erased through processes of segregation, racialized disinvestment, and, beginning in the 1950s and 1960s, physical displacement and gentrification. Notably, Phoenix and Tucson *Green Book* locations existed almost exclusively in areas identified as either "hazardous" by HOLC's notorious red line mortgage risk maps or within zones designated as slums targeted with clearance through federally supported urban renewal programs.

3.1. Phoenix

Phoenix best illustrates the impact on *Green Book* locations of an overlapping mesh of racialized policies and practices that, beginning in the 1930s, denied Black and Hispanic neighborhoods investment and stability and then used neighborhood conditions resulting from that disinvestment as justification for slum clearance in the 1950s and 1960s (Figure 1). The area just north of Union Station and the rail yard, which contained the majority of Phoenix *Green Book* listings was described in HOLC maps as follows:

> "In the Negro section are some very good homes, considering their occupancy by colored people. Other houses in the area are cheap. There is within this area a mixed occupancy, including Mexicans, foreigners, etc."

Another area with a cluster of *Green Book* listings was described as "very ragged, occupied by Mexicans, Negroes and the low class of white people." Homeowners or would be home owners in areas deemed hazardous, largely due to the racial and ethnic makeup of inhabitants, could be denied mortgages and insurance and these areas

were often avoided by businesses such as grocery stores (Rothstein, 2017). The result was systematic, race-based disinvestment in these areas, even as a post-war housing boom benefitted homeowners elsewhere. Poor housing conditions resulting from this disinvestment was then used as justification for slum clearance efforts in the 1950s and 1960s, spurred by the 1949 Housing Act which provided federal funding for identifying and clearing blighted areas, largely in central city neighborhoods.

3.2. Tucson

Tucson was not redlined, but the traditionally Mexican American parts of the central city, which contained half of Tucson's *Green Book* listings, were labeled as blighted and cleared through the Pueblo Center Urban Renewal District in the 1960s (Figure 3). In her book about this particular urban renewal project, Otero (2010) describes a common pattern of systematic disinvestment in first half of the 20th Century followed decades later by efforts to use the results of that disinvestment to justify labeling the area as blighted in order to clear it for redevelopment.

3.3. Different displacement patterns since 1960

Nationally, about 80% of residents displaced through urban renewal were Black (Nelson & Ayers, 2020). Of the 1,223 families displaced through urban renewal in Phoenix between 1950 and 1966, 59% were families of color. This figure likely represents displaced Black families, as the U.S. Census did not include a "Spanish origin" or Hispanic until 1970. In Tucson, 1,007 families were displaced beginning in 1958 to make way for new government buildings, a convention center, hotel, and parking lots. Eighty-two percent of families were white, which likely consisted largely of Hispanic/Latino residents.

The Black populations in central Phoenix and central Tucson, areas where *Green Book* listings concentrated, has dropped since 1960. In Phoenix, the Black share of the population in these areas was 31% in 1960. This share dropped to 14% in 2000 but has remained steady from 2000 to 2018. In Tucson, the Black share of the population in central Tucson was 22% in 1960 and has continued to drop through the decades, with 4% in 2018 (Figure 4).

While the Black population of central Phoenix and Tucson declined, one key difference is evident in the data. The decline in Black population of central Phoenix occurred at a time when the overall population of central Phoenix declined at a similar rate (from just over 30,000 in 1960 to about 16,000 in 2018), largely due to physical displacement resulting from the construction of freeways and the expansion of the central business district, including office buildings, civic buildings, and sports facilities as Phoenix grew into what is now the fifth largest city in the United States. The areas of central Tucson that historically had sizable Black populations have grown in population since 1960 (from roughly 16,000 to just over 20,000) even as the Black population has dwindled from 22 percent to 4 percent. With the exception of the Pueblo Center Urban Renewal District just south of downtown other areas with historic Black populations, including several *Green Book* locations remain physically intact.

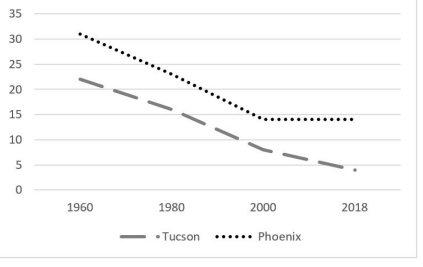

Figure 4. Black share of the population in central Tucson and Phoenix between 1960 and 2018 (Source: census data compiled from Social Explorer by author2).

CONCLUSION

This study of the locations of Arizona's urban *Green Book* listings illuminates the past ethnic and racial mixture of urban neighborhoods as well as co-occurring practices and legacies of racialized mortgage financing and displacement through urban renewal. *Green Book* listings, viewed together with HOLC mortgage security maps, Sanborn fire insurance maps, and urban renewal documents, provide a snapshot of African American spaces in Arizona cities during the early-highway, pre- and immediately post-war period. By viewing demographic and physical changes in these locations we begin to untangle a complex web of racialized policy, market, and physical interventions that have transformed these places in subsequent decades.

From the perspective of historic preservation, the temporal character of *Green Book* businesses, and the demographic changes within neighborhoods, present challenges. Current residents, who tend to write the place-based histories, no longer represent past residents; the businesses serving African Americans have left or changed; and contemporary Black travelers tour differently (Lawrence-Zuniga 2016). The conservation of districts and buildings must not only confront these absences and changes but also address the reality of past racial and ethnic diversity (Robinson, 2017). From the perspective of planning, legacies of segregation, displacement, and erasure – and their lasting economic impacts – are still very much at the fore of community conversations about contemporary planning decisions. In Tucson, for example, past urban renewal efforts have entered into conversations about transportation and other neighborhood investments in communities concerned with ongoing processes of underinvestment and gentrification (Ingram et al., 2017). This paper provides the context necessary for the work of planners, preservationists, and architects to benefit from the documentation and analysis of complex histories of race, urban renewal, and displacement.

PAPER #6.13

THE EVOLUTION OF THE SPANISH BUILDING CODES: AN OVERVIEW FROM THE SEISMIC DESIGN PERSPECTIVE

Luisa Basset-Salom[a], Arianna Guardiola-Víllora[a]
[a]Department of Continuous Mechanics and Theory of Structures, Universitat Politècnica de València, Spain

ABSTRACT

When assessing an architectural building, it is essential to know not only in which period it was designed but also which constructive recommendations and technical standards were at force at that very moment.
This information is a must when the aim of the analysis is to use consistent techniques and materials in the retrofitting or repair process, but it is also needed with regards to define the structural and constructive quality and the seismic response in the occurrence of an earthquake.
This paper establishes seven different constructive periods for the last 100 years, considering the evolution of the construction techniques and the corresponding Spanish building codes, evaluating the influence of the legislative framework in the quality of the materials, the design and execution of the structures and the consideration of the seismic loads in the analysis.
For that purpose, not only the legal framework has been analysed considering the date in which every document has been approved and published, but also the transition periods in which different codes were in force. Prescriptions and compulsory conditions have been compared discussing improvements in the proposed constructive details and calculation parameters.
Finally, a proposal about how to consider the influence of the constructive periods in the seismic vulnerability assessment has been included.

KEYWORDS

Spanish building codes; constructive periods; seismic design; architectural buildings; retrofitting.

INTRODUCTION

The Iberian Peninsula shows low to moderate seismicity (Capote 2011) with minor earthquakes, due to the convergence of African and Eurasian plates. Occasionally, earthquakes of catastrophic consequences may occur in the future with a foreseeable maximum magnitude of around 7. The most destructive earthquakes that affected the Iberian Peninsula in the past occurred before the 20th century (Martínez 2003). Fig. 1 shows the seismicity in Spain. Most of the central plateau (Castilla-Leon, Madrid, Castilla-La Mancha), the north (Cantabria, Asturias, Galicia) and the central eastern area (Castellón) are of low seismicity; the northern Provinces of Andalusia, Catalonia, Aragon, the Basque Country and Navarra are of medium seismicity, being the Betic chains (Granada, Almeria, Murcia and the south of Alicante) the most active seismic zones of the Iberian Peninsula followed by the Pyrenees.
The majority of the Spanish cities, like many other regions in the world located in areas of low or moderate seismicity, reveal a high seismic risk, due to the vulnerability of their buildings. Even though current advances in technical knowledge provide a variety of construction and structural systems to withstand seismic actions, a large number

of buildings in these cities don't fulfil the recommendations, mainly because they were built before the first seismic regulations came into force.

The objective of this paper is to organise in periods the residential buildings built in Spain during the last 100 years, taking into account the evolution of the construction techniques, the improvement of the structural materials, the design of construction details and their execution, as well as the influence that the technical standards, in force at each moment, have had on their seismic performance. The seven construction periods that have been established are described in this document. Following other Spanish researchers' recommendations (Lantada 2007, Feriche 2012) they have been grouped in pre-seismic code, low-seismic code and high-seismic code periods according to the seismic standards. The ranges of dates corresponding to each period have been defined considering the approval of the different regulations, as well as the transition years in which different seismic codes were in force.

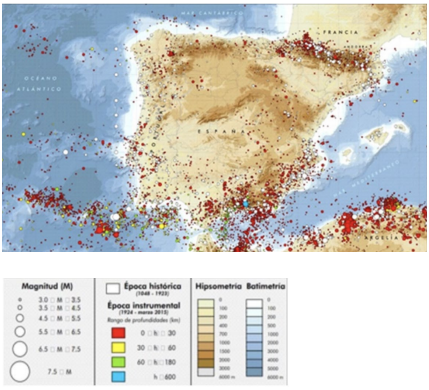

Figure 1. Seismicity in Spain. Source: (Instituto Geográfico Nacional 2015)

1. PRE-SEISMIC CODE BUILDING CONSTRUCTION PERIODS

Three periods are defined before the approval of the first Spanish seismic standard came into force, namely, prior to 1940, from 1940 to 1962 and from 1963 to 1968.

1.1. First period: Prior to 1940

The main characteristics of the first period (prior to 1940) are the absence of technical building regulations and the poor quality of the building practices.

Since the end of the 18th century, most of the Urban Police ordinances requested, for every construction work, to present a scale drawing of the building plan and elevation, signed by the Master Builder, and lately, in the 19th century, signed by the Architect in charge of the technical project management and supervision. One of the main duties of the Mayor Master Architect (Age of Enlightenment) and of the Municipal Architect (technical municipal body created by Royal order in the 19th century) was "*to examine the design and to correct any defect that exists, both in terms of solidity and in terms of symmetry and good shape*" (Anguita 1995). However, in practice, these bylaws were seldom adopted, and it was common that projects at that time lack of any architect or technical project supervisor.

The prevailing vertical structural system in this period consisted in load-bearing unreinforced masonry walls without any bracing system, designed to withstand only gravitational loads. The horizontal structural system changed from timber beams and joists floors to cast iron[1] beams and joists floors at the end of the 19th century and finally, since the first quarter of the 20th century to reinforced concrete floors.

At that time, timber and cast iron floors were calculated by means of tables. As an example, Fig. 2 shows two tables to design cast iron beam floors, a novel structural

[1] The main difference between cast iron and steel is the presence of carbon. Alloys with a carbon content higher than 2.1% are known as cast iron, being the carbon content of structural steel around 2º/$_{00}$

system in Madrid in 1883. These tables and the explanation of their practical application were proposed by Page (1883), director of public works, in a paper published in the Public Works Journal. In 1925, this journal, published a similar article about the construction of reinforced concrete floor slabs (Laffon 1925). In this paper, the author (a civil engineer) explained his personal experience in the dimensioning of the tension and compression reinforcement of a site-cast concrete rib with the abacus of Fig. 3.

In this period, apart from the fact that there weren't any regulations applicable to the calculation of the structural elements, there were no requirements regarding the minimum documents and the level of detail required to apply for a construction permit. Projects used to contain a distribution plan, a drawing of the facade and a short technical report that barely included a brief description of the construction work that was intended to be done in terms of materials and structural elements. The technical report of a project signed by Joaquin Rieta in 1931, can be seen, as an example, in Fig. 4 (Rieta 1931).

"We do not think that these tables require any explanation, however, to facilitate their application we will give them:
Table number 1 gives the loads that the floors must bear, according to the uses to which they are destined, loads that, as it is seen, vary from 300 to 600 kilograms per square metre, and it is the first one to be consulted.
Determined that load, for example, 350 kg per square metre, which is what we have adopted in our constructions, which we classify as ordinary houses, we look for table number 2: first the row in which this load appears; second, the average distance between beam and beam, equal for all floors, which in the present case is 0m,60; and third, the bay or span width, which varies in our case from 4m,50 in the basement to 5m,40 on the fourth floor, so considering the average, which is 4m,95. Finally, it is obtained from the same table the height of the above mentioned beams: 16 centimetres, and its weight per linear metre: 15 kilograms.
To complete this work, the dimensions of these double T beams must be detailed; but once given the height and weight, the best iron distribution cannot be done better than by the manufacturer."

Figure 2. Tables for cast iron beam floors design. Source: (Page 1883)

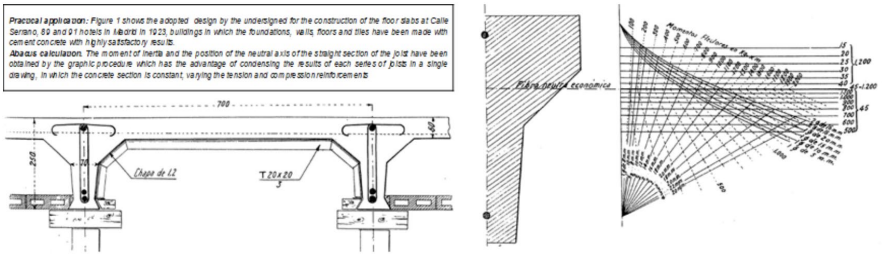

Figure 3. Design of reinforced concrete floors and abacus. Source: (Laffón 1925)

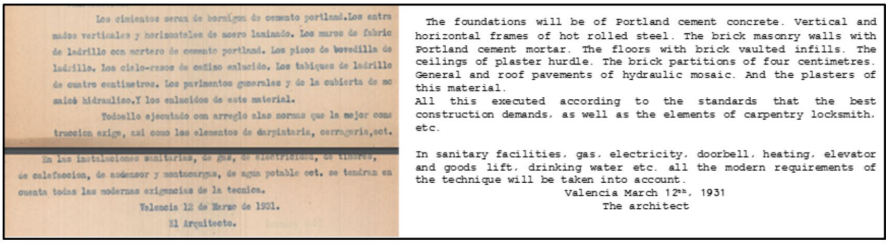

Los cimientos serán de hormigón de cemento portland. Los entramados verticales y horizontales de acero laminado. Los muros de fábrica de ladrillo con mortero de cemento portland. Los pisos de bovedilla de ladrillo. Los cielo-rasos de enlucido. Los tabiques de ladrillo de cuatro centímetros. Los pavimentos generales y de la cubierta de mosaico hidráulico. Y los enlucidos de este material.

Todo ello ejecutado con arreglo a las normas que la mejor construcción exige, así como las elementos de carpintería, cerrajería, ect.

En las instalaciones sanitarias, de gas, de electricidad, de timbres, de calefacción, de ascensor y montacargas, de agua potable ect. se tendrán en cuenta todas las modernas exigencias de la técnica.

Valencia 12 de Marzo de 1931.

El Arquitecto.

The foundations will be of Portland cement concrete. Vertical and horizontal frames of hot rolled steel. The brick masonry walls with Portland cement mortar. The floors with brick vaulted infills. The ceilings of plaster hurdle. The brick partitions of four centimetres. General and roof pavements of hydraulic mosaic. And the plasters of this material.

All this executed according to the standards that the best construction demands, as well as the elements of carpentry locksmith, etc.

In sanitary facilities, gas, electricity, doorbell, heating, elevator and goods lift, drinking water etc. all the modern requirements of the technique will be taken into account.

Valencia March 12th, 1931

The architect

1.2. Second period (1941-1962)

After the Spanish Civil War, an increase in the economic stability favoured the improvement of the constructive systems and the use of better-quality materials

In 1941, the first antecedent of the Spanish technical regulations was approved: Regulation for the application of the Decree on iron restrictions for buildings (*Reglamento para aplicación del Decreto sobre las restricciones del hierro en la edificación*, BOE 02/08/1941). This document established the "Technical standards of knowledge and unavoidable application" to be considered in the calculation and execution of every construction work in which iron was to be used. One of the recommendations for the reinforced concrete framed structures (the most common in this period) was the removal of the compression reinforcement in all the beams and the reduction of the reinforcement in the structural elements under combined bending plus compression. Fig. 5 shows the first part of this Regulation. In article 2, the concepts of permanent and imposed loads, respectively, are defined for the first time, specifying the values that must be adopted in the structural analysis. However, what is most significant in this document is the restriction on the use of iron, a circumstance that, on the one hand prevented the design and construction of steel structures, moving away once again from the trends in Europe and, on the other hand, forced the reduction to a minimum extent of reinforcements in reinforced concrete structures, leading to the execution of a low-strength concrete. The specification regarding the iron restrictions in floors is included in Fig. 6, while Fig. 7 shows an excerpt from a technical report signed in 1941, justifying the reduction of iron in concrete columns following these requirements.

In 1944 came to force, with minor changes, the first code for design and execution of concrete works, (*Instrucción para el Proyecto y Ejecución de Obras de Hormigón*, BOE 1/6/1944) formerly published in 1939 (BOE 16/2/1939) but subject to further confirmation. It was mandatory only for public works.

GOBIERNO DE LA NACION

PRESIDENCIA DEL GOBIERNO

REGLAMENTO para aplicación del Decreto sobre las restricciones del hierro en la edificación de 11 de marzo de 1941 (BOLETIN OFICIAL del 12)

NORMAS TECNICAS

CAPITULO PRIMERO

Art. 2. For the purposes of an exact interpretation of the precepts contained in these technical standards, the following general concepts are established:

a) Permanent load: sum of loads that invariably act in the construction (self weight of structure, floors, pavements, partitions, etc.).

Self weights of the different construction elements will be established according to the following values:

Laminated iron, 7,850 Kg/m³.
Wood, according to its nature and state, 800 to 1,000 Kg/m³.
Natural stone masonry, 2,500 to 2,800 Kg/m³.
Ceramic brick masonry, 1,800 Kg/m³.
Hollow brick masonry, 1,300 Kg/m³.
Mass concrete, 2,200 Kg/m³.
Reinforced concrete, 2,400 Kg/m³

b) Imposed loads: loads representing the weight of people, furniture, stored products, etc., and, in general, any load which is not permanent.

The following imposed loads will be considered for the calculation of the iron structure, provided that the need for higher values is not justified:

Housing 150 to 200 Kg/m².
Offices, 200 to 250 Kg/m².
Public buildings, 250 to 300 Kg/m²
Showrooms 400 to 500 Kg/m²
Garages (light cars), 350 to 400 Kg/m².
Roofs, 150 Kg/m²

In warehouses and other constructions dedicated to special uses, loads will be fixed according to their destination.

Prior justification, loads other than those established may be allowed, as well as in cases where it is necessary to take into account dynamic effects, in which the following increases will be fixed: Venues for shows and meetings in which people can get up at the same time, 50 percent, Structure cases that have to withstand dynamic effects produced by machinery, etc., 25 percent.

Figure 5. Regulation for the application of the Decree on iron restrictions for buildings. Art.2, permanent and imposed loads. Source: (BOE 12/03/1941)

2ª *Peso de hierro.*—Para el empleo de hierro en forjados de pisos (viguetas) el peso máximo total permitido será el siguiente:

Luces menores de 3 metros, 10 Kg/m2 y planta.
Luces menores de 3.5 metros, 12 Kg/m2 y planta.
Luces menores de 4 metros, 15 Kg/m2 y planta.
Luces menores de 4.5 metros, 18 Kg/m2 y planta.
Luces mayores de 4.5 metros, 21 Kg/m2 y planta.

Para obtener la superficie anterior se emplearán las luces libres de las crujías.

Cuando además de los entramados horizontales se hiciera uso de otros elementos permitidos, no se podrá sin previa autorización de la Dirección General de Arquitectura rebasar en ningún caso la cantidad de 10 kilogramos por m3 de edificación, descontando para esta determinación el volumen de patios.

Para los efectos de este artículo se considerarán los pesos teóricos dados por los catálogos de hierros y perfiles laminados.

2º Weight of iron: for the use of iron in floors (joists) the maximum allowed weight is:

Spam smaller than 3 m, 10 kg/m² and floor
Spam smaller than 3,5 m, 12 kg/m² and floor
Spam smaller than 4 m, 15 kg/m² and floor
Spam smaller than 4,5 m, 18 kg/m² and floor
Spam bigger than 5 m, 21 kg/m² and floor

To obtain the former area, the spam of the bays will be considered

When, additionally to the steel floors, different allowed elements were used, it is forbidden, without a permit of the General directorate of Architecture to exceed in any case the amount of 10 kg/m³ built, taking away, for this calculus, the volume of the patios.

For the effects of this article, theoretical weights provided by iron and steel cross sections catalogues should be considered.

Figure 6. Regulation for the application of the Decree on iron restrictions for buildings. Iron restrictions in floors. Source: (BOE 12/03/1941)

Estructura.- El edificio que se piensa construir tendrá una estructura de hormigon que se ha calculado a base de reducir, todo lo posible el hierro de la armadura.- En este sentido, se proyecta, en lo que hace referencia a pilares centrales, la construccion de 6 pilares de 0.30 x 0.30 armados con 6 redondos de 20 mm. hasta el piso 5º continuando estos pilares en proporcion de 20 cm. x 30 cm. y 6 redondos del 16 hasta el resto de la altura.-

Los pilares de medianera estan formados en toda su altura por pilares de 0.20 x 0.30 y cuatro redondos de 20 mm. hasta el 5º piso, siendo el armado de estos pilares a partir de este piso, cuatro redondos de 16 mm.-

Structure: The building that is intended to be built will have a concrete structure that has been designed reducing, as much as possible, the iron of the reinforcements. In this sense, in which refers to the central columns, the design consists in the construction of 6 0.30 x 0.30 columns, reinforced with 6 rebars of 20 mm. up to the 5th floor, continuing these columns in proportion of 20 cm x 30 cm and 6 rebars of 16mm to the rest of the height.

Columns at party walls are designed in all their height by columns of 0.20 x 0.30 and four rebars of 20 mm up to the 5th floor, being reinforced these columns from this floor, with four 16 mm rebars.

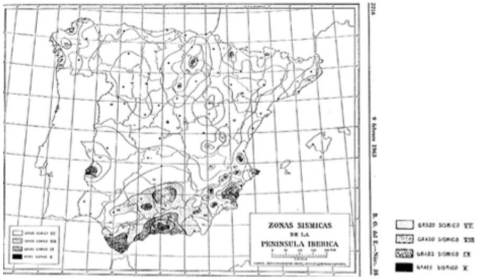
1.3. Third period (1963-1968)

The beginning of the third period is marked by the publication of the MV 101, Actions on Buildings (*Acciones en la Edificación*, BOE 9/02/1963). Although not a seismic code, it was the first time that seismic actions were included in a Spanish regulation. These actions were to be considered, compulsorily, in cities with a seismic grade on the Wood-Newman Modified Mercalli Intensity Scale (also known as Modified Mercalli Intensity, MMI) equal to or greater than VII, being optional to take them into account in cities with a seismic grade equal to or smaller than VI. Fig. 8 shows the established seismic zones in Spain according to the values of MMI.

The horizontal seismic load was obtained from the vertical gravitational load acting on the structural element multiplied by the seismic coefficient, obtained from the table in Fig. 9, according to the building type and the seismic grade of the city.

Furthermore, this standard repealed the restrictive provisions of the use of iron in buildings. Consequently, the quality of the reinforced concrete structures with respect to the previous period was improved.



Cities with seismic grade equal or bigger than VII:
Almería,
Córdoba
Coruña
Jaén
Pontevedra
Sevilla

Cities with seismic grade equal to VIII:
Badajoz
Cádiz
Granada
Málaga
Murcia

TABLA 7.2 **SEISMIC COEFFICIENT** COEFICIENTE SISMICO

Tipo de construcción **Building Type:**	Valor del coeficiente sísmico en localidades cuyo grado sísmico es: **Value of the seismic coefficient in locations where the seismic grade is:** ≤ VI	VII	VIII	IX	X	
Construcciones enramadas sobre:						
a) Terrenos compactos (rocas, gravera y arenosos gruesos, arcillosos duros, etc.)	0	0.02	0.05	0.07	0.10	Compact soils (hard rocks, gravel and thick sand, hard clay etc.
b) Terrenos semicompactos (arenosos finos, arcillosos semiduros, etc.)	0	0.04	0.08	0.10	0.15	Medium dense granular soils (thin sand semi-hard clay)
c) Terrenos blandos, arcillosos blandos y fluidos, etc.) y construcciones sobre pilotes	0.01	0.05	0.10	0.15	0.20	Soft cohesive soil and foundation by piles.
Torres, depositos elevados, casos análogos	0.01	0.05	0.10	0.15	0.20	Towers and deposits in height
Construcciones con muros de fábrica, no enramados	0.01	0.05	0.10	0.15	0.20	Buildings with masonry walls. Not-framed.
Ornamentos aislados y elementos en mensula vertical u horizontal	0.02	0.10	0.20	0.30	0.50	Isolate ornaments and cantilever elements (vertical or horizontal)

Figure 9. Seismic coefficients. Source: (MV 101, 1962)

2. LOW-SEISMIC CODE BUILDING CONSTRUCTION PERIODS

Two periods are part of this block. They are marked, respectively, by the approval, the entry into force and the years of application of the first Spanish seismic standards: The Seismic Code PGS-1 (BOE 4/02/1969) and the Seismic Code PDS-1 (BOE 21/11/1974).

2.1. Fourth period (1969-1974)

This period starts in 1969, when the first Spanish Seismic Code (PGS-1) was published. This document included very basic requirements and a static method of analysis applied to structural and construction elements, although there weren't any recommendations related to the structural design and detailing.

The national territory was classified into three zones of low, moderate and high seismicity according to the Macroseismic intensity. As shown in Fig. 10, most of the national territory was associated to zone A of low seismicity, in which the application of the standard and the consideration of the seismic actions in the structural analysis was optional.

The analysis, design and execution of the structures were improved with the recommendations of a series of mandatory standards which came into force throughout this period. It is worth mentioning, on the one hand, the Codes for design and execution of plain and reinforced concrete works (EH-68 and EH-73) and, on the other hand, two standards which focused on the structural analysis of steel structures for buildings (MV 103, BOE 28/6/1973) and on the design of loadbearing brick masonry walls (MV 201, BOE 31/5/1972), respectively. As an example of this improvement in the design, it is important to point out that the MV 201 made mandatory

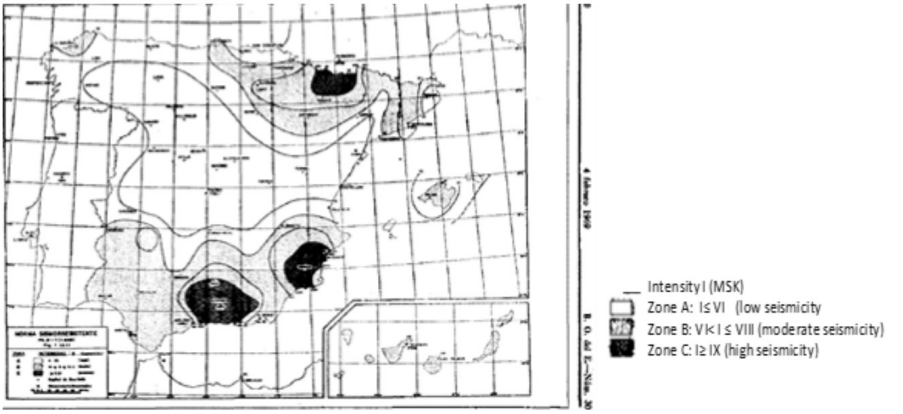

Figure 10. Seismic zones in Spain. Source (PGS-1,1968)

to connect the floors with the loadbearing and transversal walls by means of reinforced concrete ring beams.

2.2. Fifth period (1975-1996)

In this period, the structural analysis of buildings under seismic actions, defined by the Seismic Code PDS-1 (PDS-1 1974), was addressed in a more systematic way. The seismic hazard map remained nearly unchanged with respect to the map of the previous seismic code including the zones with low seismicity in which the consideration of the seismic actions in the design and structural analysis weren't mandatory.
It is also worth noting that during this period, the government decided to create a unified framework for all the building regulations, transforming the technical standards in force at that moment (MV) into the Basic Building Standards (NBE, *Normas Básicas de la Edificación*), mandatory for all the building agents (architects, construction managers, product suppliers, etc.), leading to a higher control and to a new improvement of the quality of the constructive process. Amongst them, it is worth highlighting the NBE AE-88, (Actions on Buildings (BOE 17/11/1988) and the NBE EA-95 (Building Steel Structures, BOE 18/1/1996). Several codes for design and execution of plain and reinforced concrete works (EH-80, EH-82, EH-88, EH-91) and for prestressed concrete works (EP-77, EP-80 and EP-93) and a set of non-mandatory Standards, but good building practice recommendations called Building Technological Standards (NTE, *Normas tecnológicas de la edificación*) were also published during this period.

3. HIGH-SEISMIC CODE BUILDING CONSTRUCTION PERIODS

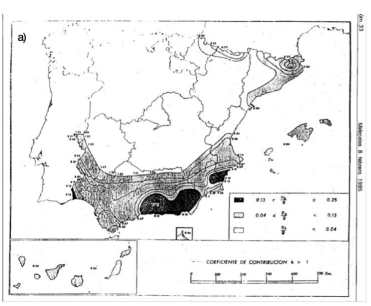
Two periods are identified as high-level building construction periods with regards to the seismic regulation. They are defined, respectively, according to the entry into force of the Spanish Codes for Seismic Design of Buildings NCSE-94 (NCSE-94, 1994) and NCSE-02 (NCSE-02, 2002) which included for the first-time technical design and constructive prescriptions.

3.1. Sixth period (1997-2004)

The beginning of the sixth period is established in 1997, just after the two-year transition from the Seismic Code PDS-1 to the new Spanish Code for Seismic Design of Buildings, NCSE-94 (BOE 08/02/95).
This document was a turning point in the Spanish seismic standards, since it included design and constructive prescriptions in addition to defining the parameters and methods of structural analysis, leading to a significant qualitative improvement.
The seismic hazard map, based on probabilistic studies, was presented, for the first time, in terms of ground acceleration, instead of intensity, providing the value of the basic seismic ground acceleration (a_b) across the country for a 500-year return period (Fig. 11 a).The application of the NCSE-94 was mandatory for buildings of normal importance located in areas with a basic seismic ground acceleration (a_b) equal or bigger than 0.06g, increasing, consequently, the number of cities which should consider the seismic actions in the structural analysis and comply with all the design prescriptions.
The code identified three methods of structural analysis namely the modal spectrum analysis, the dynamic analysis and the simplified design method, in which the dynamic earthquake effects were approached by horizontal static forces applied to the structure. This method could only be used for building structures which met several requirements related to the geometric, stiffness and mechanic regularity, the number of storeys above ground level or the building height among others.
It is worth pointing out the approval of the Code on Structural Concrete, EHE-98 (BOE 13/1/1999), which included, for the first time, the plain, reinforced and the prestressed concrete in an only document. According to this code, the minimum values of the compressive strength for plane and reinforced concrete were increased up to 20 N/mm^2 and 25 N/mm^2 respectively.

3.2. Seventh period (2005 up today)

The current Spanish Code for Seismic Design of Buildings NCSE-02 (BOE 11/10/2002), was approved in 2002, establishing a regulatory adaptation period of two years. Its mandatory enforcement, in 2005, marks the starting point of the seventh period.
The seismic hazard map (Fig. 11b) has minor changes with respect to the one presented in the NCSE-94, but it was updated in 2015, after the Lorca Earthquake (11^{th} May 2011), by the Instituto Geográfico Nacional (IGN 2015).
The novelty was that the application of the NCSE-02 is mandatory for buildings of normal importance located in areas with a basic seismic ground acceleration (a_b) equal or bigger than 0.04g, or equal or bigger than 0.08g when the frames are effectively braced in all directions.
Apart from this, the most relevant improvement consists in the seismic detailing requirements to achieve better ductile structural behaviour.
The Building Act (*Ley de Ordenación de la Edificación*, BOE 06/11/1999), approved in 1999, established a building regulatory system with a performance- based approach, setting in terms of objectives the Basic Building Requirements on functionality, safety and habitability which were developed, subsequently, in the Spanish Technical Building Code, CTE (BOE 28/03/2006), approved in 2006. The CTE comprises a set of different Basic Documents, currently in force, to guarantee the fulfilment of the above-mentioned building requirements such as structural resistance, serviceability, durability, robustness, among others.



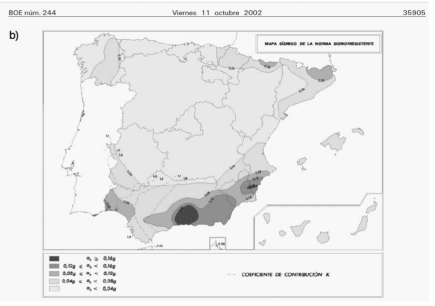


Figure 11. Seismic zones in Spain defined by a) NCSE-94; b) NCSE-02. Source: (NCSE-94 and NCSE-02)

4. INFLUENCE OF THE CONSTRUCTIVE PERIODS IN THE VULNERABILITY ASSESSMENT

The structural and the constructive quality of the buildings affect their seismic vulnerability and, therefore, their seismic performance in the event of an earthquake.

A suitable method to assess the seismic vulnerability of the residential buildings in urban areas is the Risk-UE level 1 Vulnerability Index Method (Milutinovic, Trendafiloski 2003). A vulnerability index is assigned to each building according to its typology and then adapted to the its specific characteristics by means of regional and behaviour modifiers. The regional modifiers account for the quality of the building at regional level based on the technical, structural and constructive characteristics of the buildings which are basically related to the period in which they were built, except when the building has been completely retrofitted.

Different values for these coefficients have been proposed for Barcelona (Lantada 2007), Granada (Feriche 2012) or Valencia (Guardiola-Víllora, Basset-Salom 2015), and modified considering the seismic performance of the masonry and RC buildings damaged during Lorca May 11th 2011 earthquake (Feriche et al. 2012; Basset-Salom, Guardiola-Víllora 2014; Martinez-Cuevas, Gaspar-Escribano 2016).

CONCLUSION

Despite several destructive earthquakes occurred before the 20th century, most of the Spanish cities show low to moderate seismicity. Consequently, many residential buildings show high vulnerability because they were calculated neglecting the seismic actions. To consider the structural and constructive quality in the seismic vulnerability assessment, the evolution of the Spanish building codes has been described, classifying the buildings into different periods according to the entry in force of the seismic standards.

The pre-seismic code periods (prior to 1969) are characterised by poor construction practices and absence or very basic national regulations for concrete and cast iron structures. Buildings were designed to withstand only vertical loads and suffered, for many years, a restriction in the use of iron which reduced the quality of the structures. This restriction was repealed with the approval of the MV 101, the first in representing the seismic actions considering equivalent horizontal loads.

From 1969 to 1996 (low-seismic code periods), construction and structural design were regulated by several building standards such as the NBE, the codes for design and execution of steel and concrete structures

(which were updated along the period) or the non-mandatory NTE. The seismic standards in force were, respectively, the PGS-1 (fourth period) and PDS-1 (fifth period), addressing more systematically the structural analysis of buildings but without any seismic design recommendations.

In the last two periods (from 1997), the enforcement of the NCSE 94 and the NCSE 02 caused a great impact in the seismic vulnerability of buildings, being mandatory to include the seismic loads in the structural analysis and to follow the design prescriptions. The approval of the Technical Building Code (CTE) and the Code on Structural Concrete (EHE-08) have also been relevant in the improvement of the construction quality of buildings and their seismic performance.

The regional modifiers of the vulnerability indices are defined for the most common residential buildings' structural typologies, based on the constructive periods. These modifiers can be implemented in other Spanish regions with similar seismicity and construction practices.

PAPER #6.14

THE SPECIAL PROTECTION PLAN FOR THE HISTORIC 'CIUTAT VELLA' DISTRICT (VALENCIA, SPAIN). A NEW TOOL TO APPROACH HERITAGE ENHANCEMENT AND MANAGEMENT

María Emilia Casar Furió[a], Maria José Viñals Blasco[a]
[a] Universitat Politècnica de València, Valencia, Spain

ABSTRACT

The Special Protection Plan for the historic district of the city of Valencia is a heritage and urban-use planning tool proposed by the City Council to protect the historic centre called the 'Ciutat Vella' (officially known as District 1). This district was designated as a Cultural Asset of National Interest (BIC in Spanish) by the Decree passed by the Valencian Government (Generalitat Valenciana) in May 1993.

This Special Protection Plan is a tool that unifies and adapts several urban planning and heritage rules in a single recast instrument. It will replace the five existing Special Protection and Inner-city Regeneration Plans (PEPRI in Spanish) for El Carmen, Velluters, Mercat, Seu-Xerea and Universitat-San Francesc, as well as those Special Protection Plans for the Buffer areas applied to the Cultural Assets of National Interest (PEP-EBIC in Spanish) of District 1.

This paper analyses this protection, enhancement and management tool. The methodology for this study is based on a bibliographic review of the legal documents and the Plan itself. Likewise, consultations and interviews have been carried out with experts. In addition, field research consisting in visits to the district affected by the Plan has been conducted in order to identify the existing problems on-site.

The results point out the more innovative aspects, such as: a) codifying all the heritage and urban planning legislative instruments applicable to District 1 in a single text, under the same legal standards; b) updating the current state patrimonial and urban legal system in accordance with the Valencian legislation in force; c) recognising and regulating the urban uses according to the current social situation, paying special attention to the residential and tertiary uses; and d) the enhancement and management of the architectural, urban and landscape heritage of this historic centre.

KEYWORDS

Historic centre; heritage; urban planning; legal management tools.

INTRODUCTION AND OBJECTIVES

As a heritage element, in the 20th century, sites of historic interest were addressed in numerous international treaties and conventions that highlight their value and the need for their legal protection and proper management. Examples include the Athens Charter (1931), the United Nations Conference (1962), the Venice Charter (1964), the UNESCO World Heritage Convention (1972), the Amsterdam Declaration (1975) and the Nairobi Declaration (1976), among others. Such agreements have allowed specific criteria to be consolidated and unified for application around the world. At the Spanish regulatory level, historic city centres are also considered heritage elements and can therefore be granted legal protection. Due to their double condition as a heritage element and an urban ensemble, both heritage and urban planning regulations are applicable for their protection.

The aim of this work is to analyse the successive urban planning and heritage administration instruments applied to the historic city centre of València that have led to the current regulations, which are set out in the Special Protection Plan (Plan de Especial Protección – PEP) for the "Ciutat Vella" of València that was approved on 26 February 2020. From the methodological point of view, the present work is based on the review of normative documents and specialised literature, but it also examines the current regulations and the proposals included in the Special Protection Plan for the "Ciutat Vella" of València. Likewise, consultations and interviews have been carried out with experts. In addition, field research has been conducted, consisting in visits to the district affected by the Plan, in order to identify the problems that currently exist on-site.

1. REGULATORY BACKGROUND

In this section, we will review the history of the heritage protection and urban planning in District 1, "Ciutat Vella" of València. Prior to the approval of the Spanish Constitution in 1978, the first glimpses of the legal treatment of heritage can be found in the Municipal Works Statute and Regulations (*Estatuto y Reglamento de Obras Municipales*) of 1924, the 1926 Decree governing the Protection, Conservation and Growth of Artistic Assets (*Decreto de 1926 sobre Protección, Conservación y Acrecimiento de la Riqueza Artística*), and the National Historic Heritage Law (*Ley Nacional de Patrimonio Histórico*) of 13 May 1933. In relation to urban planning regulations, there is the Land Act (*Ley del Suelo*) of 1956, which mentions the Special Plans (*Planes Especiales*) that were intended to protect historic and artistic sites and ensembles, and also the Inner-city Regeneration Plans (*Planes de Reforma Interior – PERI*). This state regulation also mentioned that it could

> *"lay down special rules for the cataloguing, conservation, restoration and improvement of buildings or urban ensembles and of natural elements or spaces, and establishes the limitation of uses or the facilities incompatible with their nature".*

Cataloguing was declared mandatory and the PERI had to

> *"contain a comprehensive study of the social and economic consequences of their implementation, justifying the existence of the means needed to carry it out and adopting the necessary measures to ensure that the interests of the population are defended".*

In addition, the law took into consideration the harmony of the sites and proposed that *"the constructions should be adapted to the environment in which they are located".*

Under these regulations, various specific assets and sites were declared to be of cultural interest, simply on the basis of their exceptional nature, their historical and artistic value being crucial in this respect, as is the case in València of the Lonja de Mercaderes (BOE 04/06/31), Baños del Almirante (BOE 16/02/44), Atarazanas-Grao (BOE 24/11/49), and Edificio del Antiguo Almudín (BOE 01/04/69), among others.

Article 46 of the Spanish Constitution of 1978 establishes the obligation of the public authorities to guarantee *"the preservation and promote the enrichment of the historic, cultural and artistic heritage of the peoples of Spain"*, as well as "*of the property of which it consists, whatsoever its legal status and to whomsoever it may belong*". Thus, in response to this constitutional mandate, the Spanish Historical Heritage Law was passed in 1985, followed by the 1992 Land Law.

The first of these two laws establishes the concept of Cultural Asset of National

Interest (*Bien de Interés Cultural – BIC*) with different categories for those elements that are recognised as having the most relevant historical, artistic and cultural value (Casar Furió, 2009). It also introduces the obligation for local councils to develop a Special Protection Plan to guarantee the conservation of the assets, in accordance with its Art. 20.1:

> *"declaring a Site of Historic Interest, Historical Site or Archaeological Zone as Cultural Assets of Interest will determine the obligation of the Municipality or Municipalities in which they are located to draw up a Special Protection Plan for the area affected by the declaration or some other planning instrument of those provided for in the legislation on town planning that, in any case, fulfils the requirements set out in this Law".*

This period coincides with an awareness of the importance of European sites of historical interest, as at that time many of them were in a state of deterioration and abandonment.
The first major attempt to enhance the value of València's historic city centre was carried out in 1984. In that year, a set of Special Protection Plans were approved en bloc for the "Ciutat Vella" District. District 1 "Ciutat Vella" is the administrative denomination currently used to refer to the historic city centre of València. These municipal plans developed the 1966 General Urban Development Plan (*Plan General de Ordenación Urbana* – PGOU), regulated by new state legislation (Revised Text of the 1976 Land Act and its regulatory development). These were plans with very ambitious objectives that basically referred to

> *"the maintenance of the road network with the generalised elimination of large operations involving the opening of new thoroughfares except for just a few cases that were deemed necessary; the maintenance of architectural typologies and urban scenes; the definition of road traffic proposals suited to the area with the progressive incorporation of pedestrian routes; the reinforcing of the residential attitude and the maintenance of the existing social structure with restrictions on the tertiary uses derived from traffic; the establishment of public facilities compatible with the historical urban structure".*

However, they were in fact a set of plans that were little more than just a declaration of intent.
In addition to this planning drawn up in 1984, the Inner-city Regeneration Programme of the old riverbed of the River Túria (*PERI del Jardín del Túria*), published in the Official Gazette of the Province on 11 October 1984, placed special emphasis on the city's urban landscape. Subsequently, a new PGOU for València was approved in December 1988. The implementation of this plan included the introduction of the planning instrument called the Special Protection and Inner-city Regeneration Plan (*Plan Especial de Protección y Reforma Interior* – PEPRI). This tool is similar to the previous special protection plans, but takes into account the heritage element in urban planning and also deals with inner-city reformation (decongestion, creation of urban provisions, community facilities, cleaning up unhealthy neighbourhoods, circulation, improvement of the environment or public services, etc.). Thus, between 1990 and 1993, the PEPRI for El Carmen (1991); Velluters (1992), Universitat-Sant Francesc (1992); Seu-Xerea (1992) and Mercat (1993) were approved, still in accordance with the State Revised Text of the 1976 Land Act and the implementation of the València General Urban Development Plan of 1988.
Shortly afterwards, in 1993, the historic city centre of València was declared a Cultural Asset of National Interest (BIC in Spanish) in the "Site of historic interest" category, in accordance with the Spanish Historic

Heritage Law (*Ley de Patrimonio Histórico Español*) of 1985.

The implementation of the aforementioned PEPRI raised expectations in view of the obvious ineffectiveness of the 1984 PEPs that they were replacing, which had not achieved any structuring actions or management models that would allow these tools to be considered really effective (Gaja Díaz et al., 2001). These PEPRIs of the 1990s generally advocated the conservation of the urban fabric and selective "sponging" (selective demolition of buildings in dense, historical urban environments to make way for public spaces or rights-of-way of some sort), with the introduction of management techniques such as expropriation.

During these years, moreover, certain competences in the 1978 Constitution were transferred to the Autonomous Communities. As a result, the Valencia Region passed its Law Regulating Valencian Urban Development Activity (*Ley Reguladora de la Actividad Urbanística Valenciana*) in 1994 and the Valencian Cultural Heritage Law (*Ley de Patrimonio Cultural Valenciano*) in 1998. These regional regulations reinforced the joint treatment of the heritage element in urban planning (Casar Furió, 2008).

With the new State 1992 Land Law and Valencian regulations (Law Regulating Valencian Urban Development Activity in 1994 and the Valencian Cultural Heritage Law in 1998) and the declaration of the historic city centre as a BIC (1993), the need arose to standardise all the regulations. Consequently, for the development and execution of the urban planning of the "Site of Historic Interest of the city of València", a series of framework collaboration agreements were entered into between the Generalitat Valenciana and the City Council of Valencia. The first agreement was the Plan of Integral Rehabilitation of València Antigua (RIVA 1992-1997), signed on 16 June 1992, for the intervention on the historic centre. Thus, a new stakeholder is introduced into the historic city, in addition to requiring the supervision of the Department of Culture and the Department of Urban Planning of the Generalitat Valenciana, along with the City Council itself for these interventions (VVAA, 1999).

For the implementation and management of the provisions of this agreement, the management offices of the València City Council were created (València Antiga S.A.) and the RIVA Offices on the part of the Generalitat Valenciana, both with a specific budget allocation for the rehabilitation of the historic city centre (Jimenez Alcañíz, 2000). These were mixed public-private initiatives, focused on redeveloping and re-qualifying the uses of urban spaces, improving the economic and commercial fabric, and providing social and cultural facilities. By so doing the aim was to rehabilitate neighbourhoods that were, at the time, very run-down and both the resident population and commerce were undergoing a sharp decline. The biggest problem in the implementation of this agreement was its high economic cost; so funding was insufficient and many goals were eventually not accomplished. However, the living conditions and quality of life in these city centre neighbourhoods improved substantially, leading to economic, heritage and cultural revitalisation, so that a certain recovery of demographics and local identity was achieved, and they also started to become a focal point for tourists.

Following this beginning, in the 21th century, the historic centre of Valencia firmly established its status as a cultural and tourist district thanks to the promotion of trade and the hospitality industry and enhancement of heritage buildings that were acting as cultural attractions or containers and institutional administrative headquarters.

However, these PEPRIs from the 1990s proved to be equally insufficient and ineffective (Gaja Díaz, et al., 2010). Therefore, in order to resolve the discrepancies that arose in

relation to urban planning interventions and heritage protection measures, in 1994 another framework collaboration agreement was signed between the Department of Culture of the Generalitat Valenciana and the City Council of València for the development and execution of the urban planning of the site of historic interest.

In the 21th century and within the legal-technical framework of the Valencian Autonomous Community, numerous urban planning regulations have been approved and modifications have been made to the Valencian Cultural Heritage Law, including the figure of "Cultural Asset of Local Interest" (*Bien de Relevancia Local Valenciano* – BRL) and subsequent independent regulation (Decree 62/2011, of 20 May, issued by the Consell regulating the declaration procedure and the regime of protection of Cultural Assets of Local Interest).

To overcome the shortcomings of the Spanish Historical Heritage Law as regards the Buffer areas of the BICs, the Valencian Cultural Heritage Law develops criteria to define them (Casar Furió and Taberner, 2010). For this reason, the Special Protection Plans for the Buffer areas of Cultural Assets of Interest (EBIC) were expressly provided for, as stated in Art. 39.3. Thus, a Special Protection Plan for the Buffer area of the Cultural Assets of Interest (PEP-EBIC 06-07) was approved to regulate the heritage, urban planning and landscaping aspects of 29 monuments in the city centre area. The Special Protection Plan (PEP-EBIC 08) was also approved for the Buffer areas of the Cultural Assets of Interest of the Puerta de Serranos, Iglesia y Convento de Santo Domingo, Museo de Bellas Artes, Monasterio del Temple, Palacio de Justicia y Ex-convento del Carmen e Iglesia de la Santa Cruz. They were finally approved in 2016.

Thus, these were the last legal-technical precedents before the approval of the current Special Protection Plan for the "Ciutat Vella".

2. THE SPECIAL PROTECTION PLAN FOR THE "CIUTAT VELLA"

The Special Protection Plan (PEP) for the "Ciutat Vella" of València derives from the 1998 Valencian Cultural Heritage Law which, in imitation of the National Heritage Law, establishes the obligation for municipalities in which a BIC is declared a "Historic Site" to carry out a Special Protection Plan (Taberner, 2016) for it. On the other hand, Art. 43 of the current Valencian urban planning regulations, which are the Law on Land Use, Urban Planning and Landscape (*Ley de Ordenación del Territorio, Urbanismo y Paisaje*) of 2014, with its modification in 2019, also includes the Special Protection Plan as an instrument of heritage management. This Law refers to the Valencian Cultural Heritage Law of 1998 (Arts. 34 and 39) to provide content for the regulation of this plan (Casar Furió, 2008). Therefore, the City Council of València detected the need for an urban plan that contemplates an adaptation of the state and regional regulations and, at the same time, combines the legal aims regarding urban planning and heritage to achieve coherence and sustainability in its management. Hence, the Special Protection Plan for the "Ciutat Vella" of València was finally approved on 13 February 2020 (BOP, no. 39, supplement, announcement of approval, 26/02/2020), its scope being the current District 1, which includes the districts of La Seu, El Mercat, El Pilar, El Carme, La Xerea and Sant Francesc (Fig. 1). This Plan will replace all previous regulations governing the historic centre. The initial diagnosis for drafting the Special Protection Plan for the "Ciutat Vella" of València (Esteve, 2020) was based on the need to:

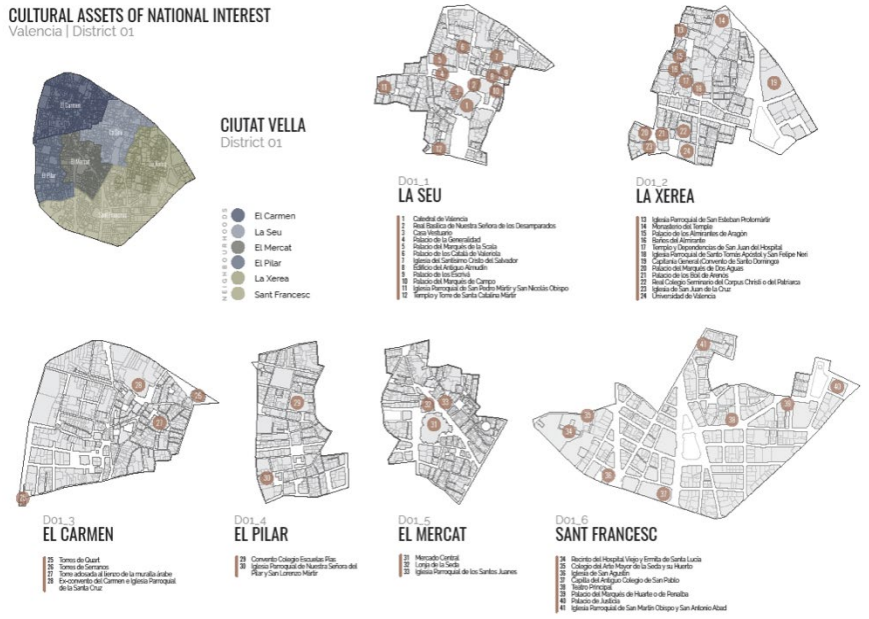

Figure 1. District 1 "Ciutat Vella" of the city of Valencia. Location of the neighbourhoods and the main Cultural Assets of National Interest (BIC).

- Update and rewrite the current plan
- Review and update the planning standards in order to guarantee a minimum level of quality in the urban planning actions that are carried out
- Recover deteriorated areas
- Conserve and enhance the value of cultural heritage
- Recover the residential fabric and the quality of housing
- Establish sustainable management of District 1 on an environmental, social and economic level
- Coordinate these actions with the current Municipal Urban Mobility Plan
- Activate and revitalise uses and activities in the neighbourhoods that make up District 1.

This Plan was developed within the framework of a broad process of public participation implemented in four phases (from October 2016 to November 2019), and taking into consideration the phenomenon of "touristification" that had been affecting the district's neighbourhoods for some time.

With regard to the updating and recasting of the current plans, it should be underlined that the Special Protection Plan will involve the homogenisation of criteria as a result of the need to adapt and unify the planning of "Ciutat Vella", which is characterised by having been regulated in a dispersed way for more than 20 years. Thus, at present, a single document brings together all the urban planning determinations of the historic urban landscape of District 1 of the city of València.

In addition, this Special Protection Plan applies to a wider area as it includes the former riverbed of the River Túria, from the Puente de las Artes to the Puente de la Exposición. On the other hand, it takes into consideration the determinations of the Sustainable Urban Mobility Plan (Plan de Movilidad Urbana Sostenible) of the city of València (2013) in relation to the urban layout, the accessibility and parking of vehicles and the pedestrian routes. The Plan thus addresses mobility as a binding determination of the planning, which tends towards facilitating the full pedestrianisation of the city centre and the use of bicycles.

With respect to the quality of the urban development actions, the Plan is oriented towards preserving the historical site, and considers the public space a priority scenario in the social life of the citizens. It was assumed that the public spaces were executed with low quality in this district (Esteve, 2020); for this reason great attention is paid to "neighbourhood or proximity facilities", as opposed to the large facilities "at the city level". It also complies with the Strategic Housing Plan of the city of València (*Plan Estratégico de la Vivienda de la ciudad de València*), approved in December 2017 for the period 2017-2021, which includes the social housing policy and social housing rental assistance in the historic centre. Moreover, according to the justification report of PEP 2020, the aim is give preference to adapting the use of provisions to meet residential needs, by promoting educational-teaching facilities, among others.

In this Special Protection Plan, cultural heritage is considered a crucial identity landmark of society and more than 2,000 heritage elements (cultural, natural and scenic) have been catalogued as protected, including BIC, BRL and new elements. It is important to point out that the Legal Register of Protections (*Catálogo de Protecciones*), as an annex to the Special Plan, includes for the first time in València, with a specific regulation within the plan itself, the protection of modern 20th century architecture. Thus, it includes elements from the DOCOMOMO Ibérico Register (Documentation and Conservation of buildings, sites and neighbourhoods of the Modern Movement).

Also relevant is the regulation that the Plan proposes for the subzone of the city, established in the detailed ordinance, called "Trama Histórica" (Historical Layout) where, as regards new buildings, it suggests particular building ordinances related to respect for and dialogue with the inherited scenarios and the traditional typologies, in close harmony with the old buildings.

On the other hand, one of the main challenges of this Special Protection Plan is the recovery of the population and the residential fabric before the advance of the tertiary use of the historic city centre, especially tertiary by the hospitality trade. Prior to 2018, there was a high demand in the city for exclusive tertiary licences for protected buildings in the historic centre (Ayora, 2019). In this way, the limitation and regulation of tertiary uses in the residential areas of the district are addressed based on checking the growth in the number of tourist apartments, among other measures. The Plan also assumes the regulation of tourist uses, achieved with the urban planning technique of zoning. Thus, it proposes a new tertiary use, called "Tourist Housing", with two modalities, the so-called "V1 Tourist Housing", which is admitted within the area of residential classification as compatible, and the so-called "V2 Tourist Housing", which is admitted as a building for exclusive use in the predominantly tertiary areas, both cases subject to certain requirements and in accordance with the regulations on urban planning stipulated in the Plan.

It seems that a lot of attention is going to be focused on the issue of the tertiarisation and the "touristification" of the historic centre in the near future, because since the Plan was drawn up until now, the growth forecasts for the tertiary sector have already exceeded the estimates made.

CONCLUSIONS

As final considerations, it can be noted that:

- The Special Protection Plan for the "Ciutat Vella" of València constitutes a great regulatory advance due to the fact that a single urban planning instrument for a historical complex includes and homogenises State, regional, heritage and urban planning regulations regarding its organisation and management.
- It is a widely debated social document, implemented within a broad framework of public participation. It has gone through four phases of public participation where the allegations made have been taken into account at all times throughout the process. However, we believe that amendments made in 2019 to the Valencian Law on Land Use, Urban Planning and Landscape have made the current regulations more accurate (closer citizen participation in the public participation provided for in Art. 49 bis) since, for the first time, the Valencian legislator provides for public consultation before drawing up the first draft of the Plan.
- The Plan has a highly protectionist vision as regards heritage; it presents a large number of protected assets, which will make it a complex management challenge.
- It is a tool that was intended for public use from the outset, with regulation of uses bearing in mind residential use as a priority (it protects residential use in the majority of buildings in the centre; the constructed floor area of non-residential premises is limited; a transitory system is implemented for occasional tourist housing). However, this is a challenge because it is anticipated that it will be difficult to attract a stable population on a permanent basis.
- One of the great challenges of this Plan will be to manage the restriction on tertiary use, which today, shortly after the approval of the Plan, is already exceeding the growth forecasts.

ACKNOWLEDGMENTS

The authors of this work would like to thank Dr Francisco Taberner for revising the text. Likewise, they are also grateful to the architect Inés Esteve for her help and advice regarding certain technical issues that arose during the research on this paper.

PAPER #6.15

OVER-ELEVATION AS A MEASURE OF URBAN RENEWAL

Maria Piqueras Blasco[a], Ernesto Fenollosa Forner[b]
[a] Universitat Politècnica de València, Spain
[b] Depart. of Continuous Mechanics and Theory of Structures, Universitat Politècnica de València, Spain

ABSTRACT

Demographic growth has promoted new approaches of cities development. Although extensions are a recurrent practice, this work focuses on the extensions in height through increased building volume. This method, in addition to increasing the demand for housing, promotes urban renewal. The chosen buildings always have an added value such as their privileged urban zoning or their aesthetic component. In this type of expansion, industrialized construction is the form of intervention that takes advantage. These over-elevations are previously manufactured in an industrial unit, where the main elements of structure are assembled, as well as enclosures and conditioning systems. The result forms different modules that are embedded together at the corresponding location. This way of working is given by the need to generate new homes with a higher level of energy efficiency and sustainability, and with a reduced construction time in the building site itself. The reduction of working hours is one of the main advantages; nevertheless, the predominant obstacles are the assembly of the modules with the existing construction. Therefore, advantages and disadvantages of this new form of execution are assessed, with methods and periods substantially conditioning this constructive practice.

KEYWORDS

Cities; over-elevations; buildability; offsite; industrialized construction.

INTRODUCTION

Throughout history, cities have experienced substantial population increases. Urban morphology and mode of growth have been affected accordingly. As an example, a fact that significantly marked the growth of the city was the Industrial Revolution, from hosting 3% of the world's population to 13%. This percentage was already 50% in 2007 and is expected to continue to rise (Joan Artés 2018, 370). In this rapid evolution, current cities have covered these needs in different ways, and it is common to see the creation of a model of city that increases its extension, is often dispersed, disordered and inefficient (José Bailach 2018). In the face of this rapid development, which causes uncontrolled land use and consumption, a new model of compact, more efficient city with optimised infrastructures, reduced environmental impact and, therefore, lower energy consumption can be considered. This choice results into a more sustainable city model. This new model of city, in view of the need for new surface area proposes underground spaces and new heights, and therefore an increase in buildability. The extension in height takes advantage of the volumetry allowed by the urban planning regulations not consumed by the existing building (Joan Artés 2018, 369). This practice means an elevation of the existing building in exchange for an improvement of common elements such as facades or conditioning systems. All this improvement, promotes an urban re-activation in the central areas of the cities, which by their antiquity probably need a restoration. We could refer

to the architects Lacaton & Vassal, who in many projects propose the adaptation of architecture against demolition and subsequent construction. The approach of this study is based on "Working with the existing," to revalue and reuse the built elements. In addition to responding to current issues such as flexibility or sustainability (Druot, Lacaton, Vassal, 2007). While this expansion strategy generates a benefit for the city's architectural heritage, it should not be forgotten that new housing must respond to a sustainable model, and respond to concepts such as Net Zero Energy Building (Net ZEBs), that is, low energy demand buildings powered by renewable energy systems (Garde et al. 2014). In this study we will focus on the residential sphere, considering both the existing building and the newly generated dwellings.

1. METHODOLOGY

During the course of this research, we have consulted different proposals that companies and offices are making nowadays, especially in the city of Barcelona, where several firms are making multiple penthouses in the nineteenth-century quarters. Based on documentation from these enterprises and bibliographic consultations, a critical view of this technique has been drawn up and frequent solutions in this type of construction of over-elevations, have been compared.

2. BUILDING EXTENSIONS. A RECURRING PRACTICE

Over-elevation in existing buildings is a relatively current option. However, extensions of buildings, in public ones or single-family housing, have been a very common practice. The dynamics of any extension are led by two clearly differentiated actors. The first is the primitive element, understood as the starting point. The second element is the new volume or surface area, which must adapt to the conditions of the first one and the urban and technical regulations. The most common extensions in architecture usually correspond to a horizontal extension (fig. 1.A). There are numerous designs such as the extension by David Chipperfield Architects at the James Simon Gallery, or the extension of the Reina Sofía Art Centre by Jean Nouvel, or even the Bois-le-Prête by Druot, Lacaton & Vassal housing tower, a very visual example of expansion and remodeling in residential buildings. Another form of extension corresponds to the connection of two separate buildings which are connected through a junction element, for instance a footbridge or even an underground corridor (fig. 1.B). A very recognizable example is the Skywalk Rennweg in Vienna by Studio Solid Architecture, or also the ABC Museum by Aranguren y Gallegos in Madrid. Another recurrent practice when it is not possible to build on an adjacent site is to build within the courtyard of the building itself (fig. 1.C.). This situation is most often observed in administrative buildings. On the other hand, when it is not possible to grow horizontally, it is usual to increase the surface area manipulating the cross-section of the building. A possible solution, usually employed in warehouses or shops, is the construction of a new floor or mezzanine within the main volume (fig. 1.D.). Finally, the case that we will deal with more detail in the rest of this study is the incorporation of a new volume on the roof of the pre-existing building (fig. 1.E.). An example of this construction can be found in CaixaForum Madrid by Herzog & De Meuron.

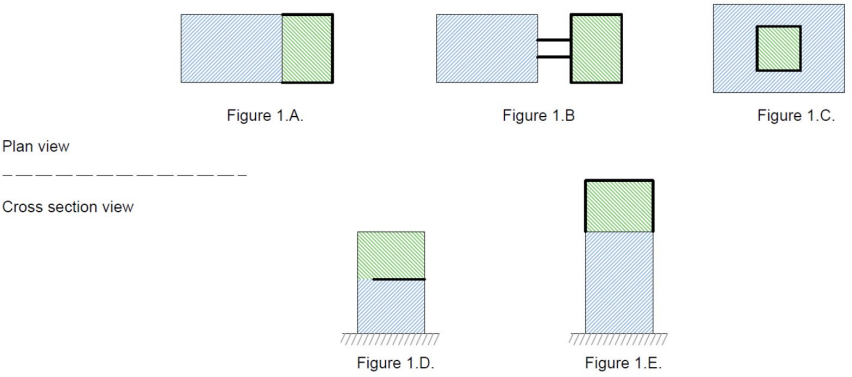

Figure 1. Schemes of expansion types, both in plant and cross-section views

3. THE OPPORTUNITY OF OVER-ELEVATING IN RESIDENTIAL BUILDINGS

This new alternative of over-elevations paves the way for historical city centres such as Barcelona, Madrid or Paris. The construction of new penthouses in residential buildings offer the possibility of reusing unused rooftop terraces to complete a city. On the other hand, the creation of new housing revalued existing buildings from the improvements made, thus helping the urban reactivating of downtown areas (José Bailach 2018).

The working methodology applied in these extensions tries to respect the values of the heritage. The roof terraces are intervened in careful way without losing the architectural value that characterizes them. Another determining factor is the industrialized building technique, which favours respecting deadlines and guaranteeing minimum qualities (Nicolás Millán 2018). In addition, this type of construction is also concerned about ecological value, aiming to get certifications such as LEED (USGBC) or GREEN (GBCe) that qualify the environmental performance (José Bailach 2018).

The total construction of the over-elevation has in general terms two phases: design and execution. During the design, and due to the high exigency of the project, it is necessary an exhaustive and complete study of the building to be completed, to know all the legal aspects of city-planning codes, the technical exigencies required by the different current regulations, the economic resources, in addition to a logistic of transport and complete assembly of the whole project. Regarding the execution, this is the most characteristic stage of this type of work and, unlike conventional work, it has two locations: initially the industrial unit where the modules are built, and finally the building which is going to receive the extension where the modules are assembled and the refurbishment and improvement work is carried out (fig. 2). These works are offered to the property in exchange for the extension of the building (Nicolás Millán 2018).

The improvement works of the building rely on several internal and external factors. Internally, these works depend on the condition of the architecture piece, either at an aesthetic, functional and structural level.

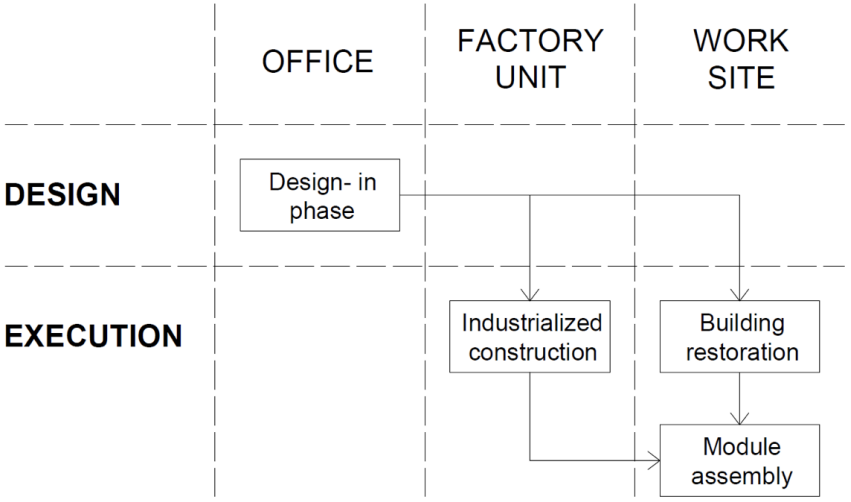

Figure 2. Diagrams of the phases that follow the projects of over-elevations

Externally, it depends on the agreement between neighbours and investors and the possibilities offered by the property object of investment.

Firstly, a study of the building deficiencies must be carried out in order to determine the actions to be taken. Once these points have been decided, all the rehabilitation and improvement work will be agreed upon based on an agreement with the neighbourhood. Normally this falls to questions of accessibility, such as works in the stairwell and lobby, incorporation of a lift and elimination of architectural barriers.

Aesthetic aspects and correction of pathologies, for example, rehabilitation of facades and courtyards, and restoration of architectural heritage elements. In addition to an improvement or replacement of obsolete conditioning systems, which must already be taken into account in the whole project due to the increase in the number of dwellings. All these improvements mean that the owners obtain, apart from the new upgrades, a revaluation of their homes (La casa por el tejado 2020).

Before receiving the new housing modules, it is necessary to have studied the viability of the intervention. To do this, it is essential to understand the structure of the building and how it works. Depending on the load to be added, the structural state of the building and the constructive and logistic conditions, the interventions will be different. Initially, we have the possible reinforcement of the foundation, where there are multiple repair and reinforcement techniques (Emma Colom 2016). If necessary, in addition to acting on the foundations and the upper structure, the rooftop terrace must be prepared to receive the new housing modules.

Once the rooftop terrace is cleared, it is time to execute the new structural elements where the modules will be supported. It should not be forgotten that the modules must be adapted to the structural elements of the existing building. The structure of these buildings is usually load-bearing walls parallel to the façade, and must

be taken into account for the support of the new modules. Therefore, the original structure will condition the new structural elements, and also the spaces.

Simultaneously to all the on-site work, the new housing modules are executed in the industrial unit thanks to the industrialised building technique. Each house is composed of different modules that are formed in a factory. All this three-dimensional structure is made of steel profiles that will be subsequently treated for both corrosion and fire as indicated by the regulations. Next, the partitioning made of plasterboard is placed. At the same time, as progress is being made with the partition walls, the plumbing, draining, electricity and telecommunications systems are installed. Finally, works on the wall coverings, tiling, flooring and suspended ceilings are solved. Once interiors are done complete, work is done on the exteriors, installing the carpentry and the façade coverings (Jon Kepa Areitio 2017).

Being the modules prepared, the transport and assembly logistics are organised for their placement at the final location. During the days of hoisting and assembly, everything has to be well planned. In addition, an organization with public roads is necessary for special transport and crane placement (Jon Kepa Areitio 2017).

Due to the type of building technique, the modules are practically finished in the industrial unit, but once there, the last details are carried out, such as joints, connection of conditioning systems, last details, waterproofing and sealing. Simultaneously, the improvement work on the existing building is being performed.

The building and the manufacturing of the modules in the industrial unit takes usually three months. Subsequently, the raising of the modules means several days. Then, the assembly of modules for new homes with the existing building and all the completions usually last between two and three months (Joan Artés 2018, 373). Therefore, the total time, without taking into account the project phase and legal procedures such as the license obtaining, is close to five or six months.

Some of the companies that are carrying out this type of construction are *La casa por el tejado*, a construction company that, in collaboration with an external team of technicians makes these houses. In addition, new companies related to this modality are emerging, such as *Growing Buildings*, which makes passive houses, or *Inbesters*, an investment consultancy for real-estate projects (Nicolás Millán 2018). It bears mentioning the *Abracadabra project*, a plan financed by the *European Commission* based on the energy renovation of existing buildings taking advantage of the creation of new housing on the roof (European Commission 2020)

4. LA MARINA 285. OVER-ELEVATION EXAMPLE IN BARCELONA

The elevation project carried out by La Casa por el Tejado is located in the Eixample district of Barcelona, at La Marina 285. The existing building has a ground floor and three floors, and it is located between party walls. On the other hand, the extension consists of the supplementation of two floors. These are the first premises for the development of the project.

The vertical structure of the building to be extended is made up of 15 cm load-bearing walls, except for the wall on the outside, which is 30 cm (Jon Kepa Areitio 2017). In addition, the type of roof corresponds to the Catalan roof. In the city of Barcelona, a large part of the buildings corresponds to a similar type of flat rooftop terrace. The peculiarity of this type of roof is its inner air chamber, with a depth between 40 and 60 centimetres (Joan Artés 2018, 374). This double-layer roof creates an air current that minimises high temperatures and prevents condensation.

First, once the structural and constructive performance of the existing building was studied, the foundation was reinforced. In this case, the option was for micro-piloting and reinforcement of the existing footings. This had

a positive effect on the rooftop, because the air chamber did not have to be demolished, unlike in other cases. Once the necessary demolitions and adaptations to the rooftop had been made, the 15x20 section concrete edge beams were installed in line with the load-bearing walls. Once the concrete has been poured, the metal plates are placed, at the points where they will receive the modules. These plates will be responsible for providing the new houses with precise flatness (Jon Kepa Areitio 2017). An important point between the extension and the existing building is the structure. In this case, the support structure of the modules had to coincide with the load-bearing walls of the lower floors, and the extension of the vertical communications nucleus. Four different types of modules were established. Therefore, we found 4 modules of 17 m deep by 3.25 m wide, 2 modules of 17x2.6 m, 4 modules of 9x3.25 m, and other 2 of 7x2.6 m, with a total of 12 modules for the two floors.

Once the roofing work had begun, another important point was the installation of an elevator and the refurbishment of the hall. Here the problem lay in the installation of the elevator because, as it had limited dimensions, the space had to be reconfigured. The first flight of stairs was demolished, ramps were added to the entrance to access the elevator, and the new electricity and water meters were relocated (Jon Kepa Areitio 2017).

Although unforeseen works may occur on site, this is not usually the case in factory construction. Once all the exact dimensions were collected and the project was completed, the company assemble the pieces in the workshop without any problem. In this case, the edges of the box were made from steel tubulars, in which the wooden slabs were placed in order to significantly reduce the load, a very important premise in this type of action. As for the enclosures, sandwich panel with SATE system (Exterior Technical Insolation System) was used, which favors the creation of a housing model with greater energy savings (Jon Kepa Areitio 2017).

Once the main square was assembled, the fire resistance treatment was carried out, using fireproof mortar for beams and intumescent paint for pillars. Then, the installation and finishing works were done, as well as the transport to its final destination (Jon Kepa Areitio 2017).

The biggest problem of this work was the assembly on site. Once the modules are being placed on the rooftop, everything has to be very measured. In this case, one of the modules was located a few centimeters away from its correct position, which caused the incompatibility of the next one. This caused temporary delays due to the displacement of the incorrect module (Jon Kepa Areitio 2017).

5. RESULTS AND DISCUSSION

This practice of over-elevation in historic-residential buildings arises from a problem of city growth. Despite this methodology favours an efficient city model, there are points to improve and to debate not only on an urban level, but also in the construction methodology itself.

At the urban level, there are many advantages. The most obvious advantage is shown in the use of the existing fabric and facilities, which are more optimised due to the increase in density of the neighbourhoods (Nicolás Millán 2018). Furthermore, the actions on the façade, the restoration of architectural elements, the levelling of coronations between buildings and the elimination of blind walls raise the value of the urban environment (fig. 3). All these improvements contribute to regenerate the city. Indeed, there are policies for the rehabilitation of neighbourhoods and sustainable development. For example, in 2007 the Leipzig Charter on Sustainable European Cities was adopted. Although these aspects are positive, it must be the urban regulations those which limit the buildability taking into account the available infrastructures of the

Figure 3. Over-elevation housing in Barcelona. Source: (Oriol Vives 2016)

city so that do not hold up and negatively affect these infrastructures (Nicolás Millán 2018).

Constructively, industrialized manufacturing has a number of benefits in itself. Due to its *off-site* concept, production is carried out in a more controlled and automated way, and therefore makes the system more productive, efficient and with a better optimization of resources. In addition, the construction is not altered by weather conditions, which often causes delays in conventional construction. All these facts entail a reduction in time and, consequently, costs. Although these favourable aspects seem to be on the investor's side, the existing building and its inhabitants also get a benefit. The control in the industry unit is higher than in conventional construction, and moreover the influence in case of human error is not that meaningful. Likewise, a high definition of the project is necessary for it to fit in its final location, the dimensional accuracy is more than evident. In fact, one of the drawbacks is observed when there is a lack of definition in the project, due to manufacturing outside the final location, any element not considered in the design, will affect the placement of the modules on site.

As mentioned before, new houses must have certain minimum quality and comfort conditions. This construction process not only guarantees these factors, but also, thanks to technology and research into new materials, makes houses more sustainable and more energy efficient. But the new housing does not only respond to energy aspects, but also to the need of reduction of load on the existing building, due to the remarkable lightness of the systems

employed (Meggers et al. 2012). In fact, this new search for materials responds to criteria of weight. Surely, the step to follow in order to achieve better results with these over-elevations is the search for new materials that guarantee a lighter, sustainable and modular systems.

Lightweight and industrialized construction is the optimal methodology for over-elevations. This requirement is given by the building to be completed, which initially was not designed for an increase of floors and, therefore, of loads. In addition, industrialized construction correctly solves the energy aspects (Meggers et al. 2012). Finally, it leads to a reduction in the time which it takes to build on site, reducing the inconvenience to a community of neighbours who will be bothered with the noise, rubble, etc. for less time.

Despite the advantages and opportunities offered by over-elevation, there is a lack of knowledge at the social, technical and constructive level about this practice, which still does not make it frequent. That means that building companies and their workforce should adapt in the future to this methodology and its required skills. Although society might be still rather reluctant, there are growing initiatives for example those by Descombes & Thieulin Architects which use the resource of over-elevation. Or projects such as *The Skyscape Rooftop House* by WARarchitect in Thailand. This new working methodology for the growth of cities is not only being applied at a particular level in different buildings. There are other types of proposals that follow along the same lines on a larger scale, such as the *Up project* in the city of Zaragoza. This proposal aims to build new passive, lightweight and quickly executed housing through the use of buildability, and a general refurbishment at a city level (José Bailach 2018).

CONCLUSION

Cities themselves offer options for sustainable and controlled growth by means of over-elevation. This possibility is not intended for outskirts or empty plots, where it would be more normal to think of brand new buildings. On the contrary, over-elevation is an opportunity for historical centres of cities and their first expansion dense neighbourhoods. It promotes the renovation and refurbishment of our architectural heritage, which on many occasions is deteriorated because of time and political and social negligence.

While at an urban level it promotes a more efficient system, the same is true at a construction level. Industrialised construction has an optimized manufacturing process. This favours the whole sequence of the work, which will benefit from a reduction in time, and therefore the inconvenience caused to the community of neighbours will be shorter. In addition, this type of construction offers a more sustainable service, with better energy value, precision and lightness. Despite the use of more sophisticated technology, new ways must be found to respond to greater comfort, energy and sustainable demands, based on modular and lightweight solutions.

PAPER #6.16

ADAPTIVE REUSE IN FRAGILE CONTEXTS. COMBINING AFFORDABLE HOUSING SOLUTIONS, NEW JOB OPPORTUNITIES AND REGENERATION OF URBAN PERIPHERIES

Elena Fontanella[a], Fabio Lepratto[a]
[a]Politecnico di Milano, DAStU – Department of Architecture and Urban Studies, Milan, Italy

ABSTRACT

The proposed contribution considers living spaces in relation to the themes of affordable housing, work accessibility, adaptive reuse of existing heritage, and regeneration of peripheral areas. It presents the first results of an ongoing research-by-design experience, undertaken at Politecnico di Milano's Department of Architecture and Urban Studies, within the "Territorial Fragilities" Project, and bringing together two lines of research dedicated to contemporary housing solutions and to town and city peripheries. The research is also developed through teaching activities as part of the "Affordable Housing" Final Thesis Studio (MSc in Architecture – Built Environment – Interiors). The aim is to define innovative housing solutions obtained from adaptive reuse of non-residential, underused or abandoned public assets (offices, schools, hospitals, depots, barracks). The architectural solutions will seek answers to profound socio-economic-demographic changes (transformation of family structure, labour market insecurity, migration) and the criticalities they trigger (inadequate space, functional rigidity, lack of targeted services, poor affordability). Housing access is often conditioned by unemployment, therefore the research challenge consists in producing scenarios where a building can become not only a home but also contribute to reactivating the finances of people who are in need of a life experience that goes beyond just a roof over their heads. In this perspective, housing is seen as a tool for starting empowerment processes – of people and buildings – that define new space and type solutions able to produce effects, especially in fragile contexts when supported by special policies. The contexts touched upon by the research are fragile areas: buildings and neighbourhoods found in town and city peripheries. The intervention aims to reinforcing economic and relational networks already present within the context, impacting the surrounding public spaces and encouraging an alternative way of living.

KEYWORDS

Territorial fragilities; affordable housing; peripheries; adaptive reuse; home-work link.

INTRODUCTION

Our contribution addresses the subject of living space designed in the perspective of access to housing, the home-work connection, the adaptive reuse of existing stock, regeneration of peripheral areas and fragile contexts. The text presents the initial results of ongoing studies developed within the "Territorial Fragilities" project put in place by Politecnico di Milano's Department of Architecture and Urban Studies. Two distinct lines of research[1] are brought together: *ForDwell*, considering forms, uses and spaces for contemporary living, and *PeriFrag*, observing projects and policies for

[1] Overall, this paper is the joint work of the two authors. However, §1 and §2 were written by Fabio Lepratto; part §4 by Elena Fontanella; the abstract, the introduction, §3 and §5 were written together.

architectural, urban and social regeneration of town and city peripheries. The argument developed here refers to the first stage of a research-by-design experience, aimed at defining new forms of accessible living, achieved by the inventive redevelopment of non-residential, under-utilized or derelict public stock. The research was developed within the Affordable Housing Final Thesis Studio at Politecnico di Milano,[2] which was a place for research and design experimentation using a multidisciplinary approach.

1. ACCESS TO HOUSING

Italian housing conditions are in a critical state, with an average regression of affordability and institutions seriously challenged in coping with the growing crisis, which also extends to new forms of fragility that affect even regular user profiles (Baldini 2010). If it is true that "one hundred years of housing policies in industrialized countries have never eliminated housing exclusion" (Tosi 2017), it is equally demonstrable that it is actually a growing phenomenon (Nomisma for Federcasa 2016), in Italy and across most of Europe (Pittini et al. 2017). There are between two and three million Italian families facing housing difficulties, many of whom suffer social marginalization (Tosi 2017). Over 1,700,000 households are at similar risk of succumbing to forms of default and loss of their home.[3] In the face of these high numbers, public housing stock, estimated at just over 850,000 dwellings, is not proportionate to the number of people experiencing acute housing difficulties.[4] This growing "fragilization" of housing conditions is a process simultaneously encountering social, spatial and institutional issues, faced with the rapid change in economic conditions and, above all, with difficulties in accessing employment and income. The sheer speed at which the latter vary impacts the population much more quickly than the ability of institutions to react with policies or of spaces to adapt to changing needs (Balducci 2018): a misalignment that accentuates social marginality, neglect, deprivation.

The correlation between access to housing and access to employment, especially in peripheral areas, has been addressed in recent programs and policies promoted by local institutions, linked to cohesion and social inclusion projects, financed at national and community level. For example, the special program for urban redevelopment and safety in peripheries launched by Naples Municipal Authority merges the right to housing with the right to work, education and training. The joint goal of the "Agenzia Sociale per la Casa" ["Social Agency for Housing"], financed with PON (National Operational Program) funds for metropolitan areas, is to counteract those housing problems generated by lack of income because of unemployment. In addition to receiving a living space, the people engaged by the program are included in guided independence courses, aimed at rebuilding employment and so indirectly resolving right to housing issues.[5]

Similarly, in Milan's Lorenteggio district, ongoing urban requalification is aided by a plan to support training, professional requalification and self-employment for the most fragile subjects and the unemployed. The aim is to strengthen the economic

fabric of the neighbourhood, in tandem with the improvement of spatial quality. The various actions envisaged, with POR-ESF funds for 2014–2020 and the European Regional Development Fund, also 2014–2020, combine support for micro-businesses and the creation of social impact enterprise. Only the future will tell if these actions are successes or failures. It is nonetheless interesting to register how housing and employment are perceived as interacting issues, which cannot be addressed separately. Moreover, what kind of space do these kinds of projects require? What role could be played by a rethinking types of living spaces? What prospects open up for abandoned public buildings in developing opportunities that combine access to housing and access to jobs? This research considers the idea of starting over from unused buildings and their repurposing, to trigger positive reactions in the relationships between spaces, societies, institutions, and economies. The boundaries of the project research are therefore determined by the recognition of two main issues: the need to act on the home–work link, and the desire to seek opportunities for reclaiming extant public – and not solely residential – stock.

2. THE HOME-WORK LINK

The problem of having access to housing is the fallout of failure to find employment. In the current conditions of uncertainty and high unemployment, a large part of the population is marginalized, without a continuous and adequate income that would allow stable access to a decent home.

The architectural relationships between work and living spaces stand as a concrete expression of the different economic models following on over time, with specific building types emerging for each model, distinguished by the ways in which the settings are conceived and organized. For example, the archetypal shared work and living space of the Medieval house-shop or the rigid functional separation, typical of Fordism (Holliss 2015). Starting from the 1970s, changing economic models brought new practices in the use of space and triggered type changes (still incomplete), which highlight how existing dwellings are often unsuitable for current needs, especially if referred to today's forms of economic livelihood (van Gameren et al. 2019). This occurs in an era where work or productive environments demand compatibility with living spaces and installation in urban areas (Melotto, Pierini 2012; Misino 2018). We refer not only conditions rendered favourable by current technologies that enable efficient remote or home working (as the spread of smart working activity due to Covid-19 pandemic has shown), but also the return of manufacturing, artisanal or digitized production, within the urban fabric (Rappaport 2015). Nonetheless, the most recurrent experiments proposing new architectural solutions do not seem to fall within the realm of affordable housing.

Among the most popular type variants, the concept of a single building accommodating "co-living" and "co-working" combinations has taken hold in Europe and the United States, also attracting attention in the academic field (Coricelli et al. 2018). It is worth pointing out, however, that this is a commercial product, targeting subjects who do not face economic problems: generally young professionals who do not see themselves in traditional housing models and are willing to commit themselves economically to live within solutions they consider most congenial to their needs. There seems to be room for exploring new architectural solutions therefore, which might offer scenarios for rethinking the status of the dwelling and transforming it into a spatial support for accommodation but also assisting in the reactivation of the finances of those requiring a housing experience that

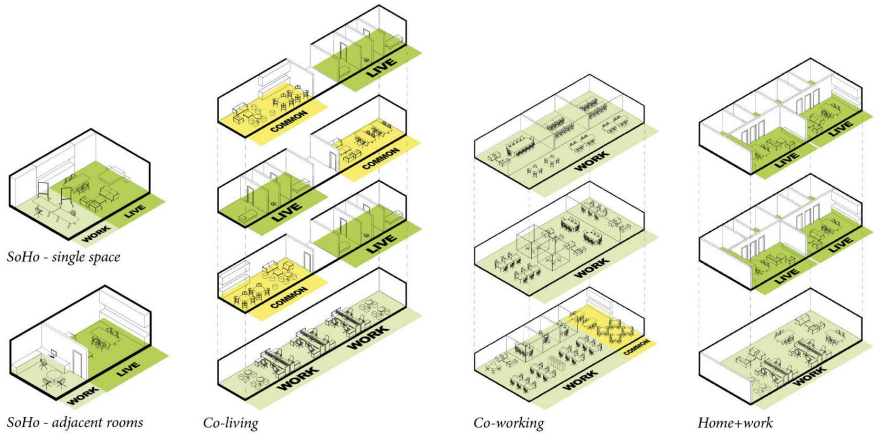

Figure 1. Contemporary housing+working models, ranging from private to public way of interaction between the different embedded activities (Cui, Mendoza 2019). goes beyond just having a roof over their heads. By combining accessible housing, a productive environment and upgrading of extant properties, a dwelling can then become a device for initiating processes to redeem people, buildings and urban contexts by defining innovative space and type solutions, integrated with targeted policies and services.

3. STARTING OVER FROM EMPTY PERIPHERAL SPACES

Italy is littered with public structures in a state of neglect but with huge redevelopment potential. As detailed by many studies and much research,[6] Italy has a large pool of unfinished works, derelict buildings, unused structures, assets confiscated from organized crime, etc. Part of the huge extent of this legacy – comprising offices, schools, hospitals, depots, boarding schools, barracks, warehouses, sports facilities, and much more – can be brought under the microscope thanks to a number of databases, including real estate surveys conducted by public authorities and made available by the Ministry of Economy and Finance, or the list of assets confiscated from organized crime, collected from the open platform OPEN RE.GI.O.[7]

Faced with the question research asks about how unexploited public assets can be put to good use in an approach seeking interaction between residential spaces and work opportunities, development potential may vary according to different factors, which include prompting from contexts, social networks, local opportunities and resources, public and private players, the type of

[7] Official platform of the National Agency for the Administration of Distressed and Confiscated Assets from Organized Crime (Anbsc): https://openregio.anbsc.it/.

artefact, its size and state of repair, the user profiles (ordinary or fragile) to be engaged.
The reference contexts correspond to areas that are experiencing or have experienced fragilization processes in the past and focusabove all on "rejects" located in town and city suburbs, where there is more marked social and material vulnerability, often accompanied by strong housing pressure. Within these town and city contexts, the presence of abandoned or underutilized buildings simultaneously represents a "fragility" and a "spatial resource". Indeed, while the presence of abandoned buildings contributes to degradation in peripheral areas (Bianchetti 2003; Petrillo 2018) by intensifying the perception of a daily absence of care, it also represents an opportunity for redevelopment that will trigger or support regeneration processes. The quest for accessible housing solutions able to integrate work opportunities and accommodation spaces becomes a chance to overturn the predominantly monofunctional residential status that is often the case in peripheral areas and contributes to the development of new centralities. This could translate into the ability to spark changes through architectural projects, acting on the spatial dimension of suburban fragility in towns and cities, while engaging social and economic fragilities. When synergies develop for housing, employment, social policies, and the regeneration of metropolitan suburbs, the effects produced by spatial conversions strengthening the home–work link could possibly contribute to generating better effects for economic and social factors. Architectural actions on abandoned buildings also aim to strengthen relationship and economic networks found in the reference context and generate further transformations to impact neighbouring public spaces, promoting an alternative way of life able to "make a city". The various options for redevelopment of buildings abandoned in the urban fabric are closely linked to the specific construction features (both in spatial and structural terms) and to the characteristics of the reference contexts. However, in more general terms, we can identify various openings that support ideas for conversion into economically accessible residential buildings that can accommodate work and production spaces, where spatial potential derives from the type of public building where neglect is prevalent. In particular, considering the presence in Italy of state-owned barracks, schools, hospitals, mental homes, and indoor markets, in a state of neglect or severely underutilized,[8] we can suppose that these types of construction lend themselves to redevelopment projects both in short-term and long-term scenarios. In point of fact, these categories frequently combine the presence of large spaces, often on the ground floor (gyms and refectories in the case of schools; canteens or garages in the case of barracks) with smaller circulation areas set along corridors (for example classrooms or hospital rooms), and with large distribution and circulation spaces. The categories mentioned feature not only individual buildings but also groups of constructions vaunting open spaces that connect seamlessly with public areas. Opening these up, and quickly, may offer an opportunity to rethink the relationship with the surroundings. These opportunities for repurposing and redevelopment could open the door to unforeseen combinations that precisely through the integration of domestic and production spaces contribute to enhancing existing areas that have lost their active role in the life of contemporary cities.

[8] The Italian Ministry of Economy and Finance completed an accurate Survey of Public Administrations Real Estate, including that in state of abandonment. The data are collected according to art. 2, paragraph 222, Law 23 December 2009, no. 191. Administrations inform the Ministry: about 80% for the 2016 survey.

4. LEARNING FROM PRACTICE: THREE CRUCIAL "INGREDIENTS"

The first step declared in the research project discussed here aims to work on integrating the more strictly private and domestic dimension of living and working the same place. It intends to observe with coherence the accessibility of dwelling and working in peripheral urban and metropolitan contexts by enhancing existing spatial resources.
In this sense, it intends to recover the complexity often found in a number of types in the past, which has gradually been lost. To do this, the (minimum) "ingredients" deemed necessary for the definition of innovative structures that would integrate living and work areas were identified and explored with reference to recent works and experiments in the Western context. This breakdown is required before proceeding to the subsequent phase of re-composition, articulation and hybridization, which will be addressed by the project in its role as an outright instrument and field of research. There are three ingredients – understood as components for pursuing the relationship between access to a home space and access to a work space – identified as "domestic spaces", "production spaces" and "shared spaces".

1) *Domestic* –in particular *affordable– spaces* can be considered an essential ingredient, beginning from adaptive reuse of non-residential public buildings, an approach that opens up the possibility of increasing the number of accessible dwellings, starting with abandoned public resources. In this respect, the Vandkunsten Architects *Apartments in the Constable School* project, put in place in Copenhagen in 2015, is a particularly relevant reference. These small student apartments were devised in a school building that had been abandoned for decades, in the up-and-coming Margretheholm district. The project focused on redevelopment of the entire building, to which a new layer was added that did not erase what already existed and allows appreciation of the brickwork textures near staircases and windows. The contrast between new and extant also permeates internal spaces, where the housing units are integrated and completed by collective spaces (areas for studying or socializing). The Gantry Studios project in London, designed by Architecture 00 + HawkinsBrown (2017), is another interesting case study of the potential of infilling work and shared space with an existing structure. Indeed, the project was born from an existing framework used as a warehouse for the 2012 Olympics and averted its probable neglect by seeing the potential for redevelopment. The twenty-one units mimic the archetypal house concept and are arranged on the three levels of the structure. Each is finished in different colours and materials, while the supporting structure was constructed from prefabricated wooden modules. These two examples take two approaches recurring in the conversion of existing structures: the first corresponds to the reutilization of the entire building, starting from the intervention on the envelope, while the latter exploits the extant as a support into which smaller elements are introduced to make the space habitable.

2) The *production spaces* intended to be integrated into the design experiments, range from more traditional types of work environments (art studios, manual workshops, ateliers, offices) to more innovative spaces linked to new forms of production, including cultural. Strathcona Village, built in Vancouver (2018) to designs by GBL Architects, shows how integrating production spaces into residential complexes can affect the base layer of buildings, combining light industrial production, commercial spaces and offices. A BETA Office project in progress in Amsterdam – *NDSM Treehouse* – develops a concept for 100 affordable studios for young emerging artists. This incremental structure built from recycled materials combines individual

workspaces with two large area for hosting exhibitions and workshops, concentrating on the interaction between private, collective and open spaces.

3) It is precisely the latter dimension, the *collective space* and "communal area", that represents a third important ingredient. Referable to both the domestic and the productive component, the communal areacan build the way to opening towards the context of reference and the local community, as in the case of the *Ru Paré Community*, which redeveloped a school into a community centre, to a design by BETA Office. In a suburban district of Amsterdam (Slotervaart, 2017), the redevelopment devised by this project refers both to the building itself and to the surrounding district, with the added aim of stimulating the local economy. The old classrooms allowed placement of different functions related to the new community centre, while the presence of a gym – initially considered an element of weakness because of its position inside the building – developed into a resource. By relocating the building's entrance to the gym and adding a vertical opening and closing system, this area became a foyer that manages the transition from the interior to the exterior. Communal areas thus became the core of the project. The case of *Hal7 Makers Corner* is also interesting for the role played by communal spaces in hybrid programs. Realized by Vandkunsten Architects in Roskilde (DK, 2017), the conversion worked on redeveloping a disused industrial shed by modifying the structure itself and installing new buildings inside it. The new building units are then made by upcycling waste, in particular by repurposing disused shipping containers. The spaces created inside the readapted and suitably insulated containers are dedicated to work and light production, while the intermediate spaces are designed to welcome both those who work inside the structure daily and as a meeting point for the local community.

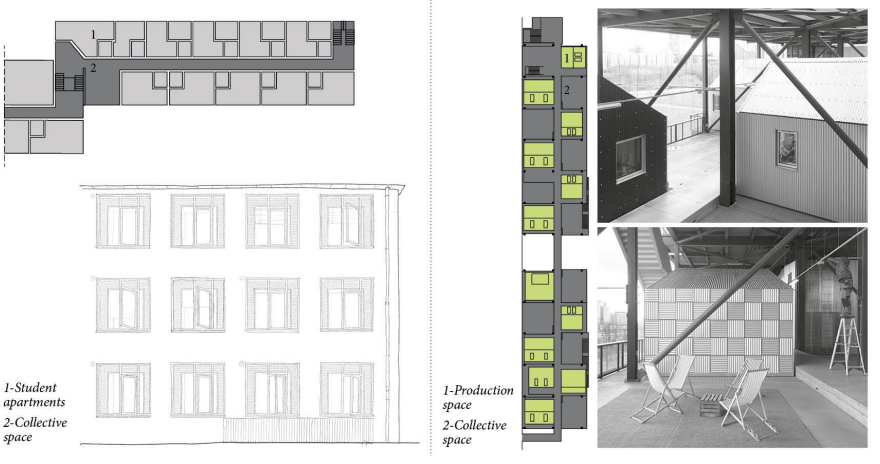

Figure 2. Two adaptive approaches to make the space habitable: reusing the entire building within the envelope (I), exploiting the extant as a support for introducing smaller units (II). CONCLUSIONS: FIVE POINTERS FOR ARCHITECTURAL DESIGN TRIALS

By studying and comparing an extensive number of past and contemporary case studies – some of which were described in the previous paragraph – we drafted initial input for defining some points crucial in outlining a possible functional program that will be tested and implemented through future research by design. These points range from the scale of functional areas to relationships within the building, and also look at the rapport with the contexts.

Domestic spaces

In an attempt to redefine living spaces perceiving them in relation to workspaces, we can define a domestic environment by suggesting a number of architectural configurations, even far removed from what we usually call "home". Finding dedicated resources and spaces for working, in an affordable housing context may require compression of private domestic arrangements, partially offset by planning for shared spaces and services. We see not only the construction of small apartments, occupied by a single-family, but also of "clusters" of rooms or mini-lodgings, grouped around communal spaces,[9] as well as independent micro units, prefabricated boxes positioned to render large-scale structures habitable, with sound and heat insulation, air-conditioning, and building services. Depending on each case, the challenge posed by finding a physical demarcation line between the home and the work environments will differ. Sometimes these two dimensions share a single space and a boundary is established simply by the time of day. In other situations, home and work are in adjacent rooms, separated by furnishings or a door, and only the actual user is involved. In yet other cases, the two dimensions are installed in the same building, connected by a distribution system, and the workers are not obliged to reside there or residents to work there.

Productive environment

The space of the productive environment can be organized to meet the requirements of different work situations: self-employed, business, contractor, etc. Some workplaces are fluid, complex to describe; others are more static and traditional. Design then needs to conceive and/or combine environments that have very different characteristics and scales: the minimum space required by a freelancer who may need nothing more than a PC; the environment required by a small business; a medium-sized production area for companies or cooperatives. In the first case, a workspace can overlap with a dwelling (Small Office Home Office – SoHo categories) or it can be integrated into shared spaces, where it is possible to rent meeting rooms or occasionally work with other professionals (co-working spaces). The latter two cases, albeit on different scales, require spaces with boundaries, properly separated from a domestic area, often for hygiene, safety or access control reasons. They include home–workshops, where the two functions interact but are separated by a boundary, and production surfaces integrated into neutral mixed-use buildings, available to host activities compatible with – even if not directly connect to – housing. In the three cases, if the working activity is visible from the outside, it is a positive element that may foster business development.

Communal areas

Communal spaces play an important negotiating role for areas in the building, first of all managing the relationship between the dimensions of personal and working lives, acting as filters to ensure coexistence of the two aspects in a single construction. Shared

[9] For instance, the Mehr als wohnen project (2009-2015), designed by the Duplex Architekten firm of Zürich.

spaces can be configured as informal areas, extremely adaptable and thus versatile in use. They may allow an integration of leisure and socialization activities and shared services (laundry, gym, communal kitchens etc ...). They are often intersected by distribution spaces, transforming stairs and corridors into timeout or observation spaces for the many activities going on in the complex. They have different levels of accessibility that correspond to just as many levels of sharing: some are aimed at the general public, others are only for the entire community of resident and/or workers who have settled in the building, or part of it. Finally, other environments can be shared by a few individual users, generally to complement their compact homes.

Adaptive reuse

The identification of abandoned public buildings can be considered a relevant starting point for definition of non-conventional adaptive reuse projects focused on the home–work relationship. If the presence of unused buildings in a state of neglect inevitably generates forms of degradation around them, regardless of their location, their redevelopment comes as a great opportunity in the urban fabric for upcycling *rejects* into *resources* to avoid further consumption of land and waste of embodied energy. The adaptive reuse of vacant public buildings can open up forms of temporary living tied to specific situations demanding immediate responses, but also be involved in long-term planning. Such time constraints will inevitably correspond to different levels of conversions, use of economic resources and materials. In a perspective targeting environmental sustainability, the latter can be identified as part of virtuous recycling and upcycling processes.

Periphery Regeneration

In peripheral areas, converting what is discarded and no longer used into resources also offers an opportunity to start or support wider-ranging regeneration processes. Within these, the relationships between living and working spaces can play an active role in abolishing residential or production monofunctionality, which is often a connotation, fostering mixité, leveraging local specificities. In contemporary suburbs, developing the home–work connection can translate into the possibility of promoting opportunities for exchange that may allow these contexts to be opened up, engaging them with their surroundings by intercepting flows and attracting a non-resident population. At the same time this could contribute to the strengthening or building – when absent – of a sense of belonging to a community and a place. In this perspective, the energies (like non-profit associations and cooperatives) already present in these territories, which very often perform different activities in these contexts in support of the local population, represent an additional resource with which experiences such as those already mentioned for Naples and Milan could come into contact and build fertile interactions.

The preliminary work presented here targets a perspective of design research commensurate to the different scales of architecture; housing, social and urban planning policies; economics; and social sciences. From a methodological standpoint, the role attributed to future architectural experimentation is considered crucial as a further investigation to increase knowledge of the described topic. The project is used as a probe capable of testing redevelopment actions in paradigmatic situations. The experiments will help to understand complex realities that intercept the material, social and institutional dimensions. The research key combined with clearly stated intentions to act are intended to produce narratives, stimulate new scenarios, asking interacting disciplinary sectors open questions, tracing generalizable and/or replicable actions that increase disciplinary knowledge.

ACKNOWLEDGEMENTS

We would like to thank Amirhossein Adelfar, Carlo Bernyak, Victoria Braile, Jiarui Cui, Vanessa Falcone, Anamaria Giraldo, Gaia Grassano, Gerardo Mendoza, Dario Michencigh, Matej Paladin: the group of students of the Final Thesis Studio "Affordable Housing: Domesticity Reloaded. Form, Uses, Spaces, Practices and Policy for Contemporary Dwelling" that developed, under our supervision, some of the drawings that are shown in this paper.
We wish to extend our special thanks to professors Massimo Bricocoli, Gennaro Postiglione and Stefania Sabatinelli for giving us the opportunity to combine our research topics within teaching activity in a multidisciplinary studio.

PAPER #6.17

SINGLE-WALL TIMBER GRANARIES BOX CONSTRUCTION IN TURKISH AND SPANISH RURAL ARCHITECTURE CONTEXTS

Ahmed K. Ali[a]
[a] Texas A&M University, College Station, Texas, USA

ABSTRACT

This paper offers a comparative overview and analytical dissections of the elements of two semi-identical vernacular structures built in similar environments but in very distant locations: The Eastern Black sea region of Turkey, and the northwest of the Iberian Peninsula in Spain. Serander of the Black sea region in Turkey, and Hórreo in Spain are two elements of vernacular architecture, which have similar appearances; functions and construction techniques. Not surprisingly, the two elements are products of similar environmental and economic conditions. Changing social and economic conditions, migration to cities, and abandoning farming has left the old structures empty but with a wealth of knowledge particularly on single-wall timber construction techniques. Unfortunately, these endangered and unprotected structures are being demolished and disappeared in a rapid rate. It is important to document, protect and preserve these unique structures, as there is much to learn from their construction methods. Various aspects of both Serander, and Hórreo are thus surprisingly similar. Both of them were built and detailed for disassembly. Many of the Hórreos are well preserved and well protected, but it is not possible to make a similar statement for Seranders, which are in the process of perishing, due to changes in economic activities and life-patterns in the modern Turkish society. This paper is based on an extensive fieldwork throughout the Eastern Black sea region during the summer of 2014 and the review of relevant literature of Horreos. A digital reconstruction of the construction assembly process was also prepared for this paper.

KEYWORDS

Vernacular architecture; hórreo; serander; single-wall timber construction; black sea region; Spain.

INTRODUCTION

Serander of the Black sea region in Turkey and Hórreo in Spain are two forgotten elements of vernacular architecture, which have similar appearances; functions and construction techniques (Figure 1,2). Not surprisingly, both are products of similar environmental and economic conditions (KARPUZ 1999). Serander is part of a rural residential typology founded by natural and economic conditions of the Eastern Black sea region. A simple single-wall timber structure constructed on posts over a platform (Ali and O'Brien 2016). This building is usually used to store grains and food, while some are used for residential purposes as guest houses. Serander consists of a front terrace (logia) called 'Çardak' or 'Sofa', and a storage space at the back. In some examples, there exist an intermediary space between the Çardak and the storage space. Seranders are classified either according to the position of the logia (positioned on either one, two, or three sides), or according to its size, in the case of which the number of load-bearing posts are taken into consideration (4-post, 4/6-post, 10/12-post). Serander often have

carved timber ornamentations, regardless of its type and size. Serander is considered as the most important adjacent structure to the typical country house in the region. Serander is constructed approximately 4-5 meters away from the rural house but close to the roadside. Anyone who is wealthy enough in the countryside would own a Serander. It is suggested that the original source and the word Serander comes from two words: "Kseros", which means dry in Pontus Greek, and "Andiro" means balcony/ terrace. Kseros" + "Andiro" = "Kserosandiro" "Kserander" "Hserander" "Serander". Which means literally drying place, "drying balcony" for corn and hazelnuts (Türk Dili Dergisi Sayı 630, Prof. DR. Hasan EREN). The Eastern Black sea region of Turkey is geographically separated from the inner regions of the Anatolian Peninsula by a chain of mountains. The four-season rainy climate created a green flora, and settlements were established at the skirts of the mountains up to 3000 meters high. Villages were established at the banks of several rivers arising from the mountains and reaching to the sea. Due to topography, an isolated culture was developed in the Eastern Black sea region (Usta 2012). In the two cities of Rize and Artvin, a rich wooden craftsmanship has been developed. Traditional wood and masonry construction methods were used in building masjids (mosques), houses and grain storages. Although an irregular settlement is commonly observed in the Eastern Black sea villages, there are clustered houses in some neighborhoods and villages. A barn is added to the house plan and placed at the ground floor due to steep terrains. A kitchen (*Aşhana*), bedroom, and storeroom were located at the first floor. The main components of the kitchen are; a stove in the middle, an oven located by one of the walls, a ground washbasin (*Suluk*), and a cabinet. Besides, a seating bench (*Peyke*), a stove, and a ground washbasin are also located inside the room. The typical Eastern Black sea house layouts were divided into two types; East of the city of Trabzon where houses with porch (*Hayat*) and west of Trabzon where houses with kitchen (*Aşhana*). Rooms were located around the porch, which is interconnected to the kitchen. On the other hand, there was no porch in the houses with kitchen, and two rooms (one is a storeroom) were connected directly to the kitchen (KARPUZ 1982). A barn is located at the ground floor and a storeroom (for milk and cheese) is connected to a kitchen. In Trabzon, a combination of stone and wood construction were used, however in Rize and Artvin, a timber log construction and masonry techniques were used (SÜMERKAN 1991).

1.HÓRREO

Hórreos are traditional rural storage buildings usually found in the northern part of Spain and primarily used for storing food and grains. The particular type of Horreos discussed in this paper is located in the Asturias, within the Iberian Peninsula (de Aldecoa 1999). Its shape and configuration are different from the traditional Galician Horreos (Rouco 2001). Hórreos were the solution to provide natural ventilation, while preventing access to unwanted rodents. They are typically built of timber, stone, or masonry with a grain chamber (warehouse box) elevated and isolated from the ground and with ventilation openings on the side walls (Perez-Garcia et al. 2010). The Iberian granaries were mainly constructed in two different materials: stone and timber. They were completely constructed of thick slabs of granite. The platform or pillars below, the frame system of the granary, the gridded walls between the frame system and even the roof were made of stone (Özcan 1999). Similar to Seranders, Hórreos were an indispensable separate structure for the locals living in the rural parts of the region. The unique structures were developed with outstanding aesthetical appearance yet surprisingly functioned as the modern fridge. Many kinds of food, especially hazelnuts and corns were dried and stored. These structures sometimes functioned as guest houses. Hórreos were typically built on 4 thick pillars. On the intersection points between these pillars and the warehouse box, wheels or disks approximately 70-80 cm diameter, a part of which is plain, and the other part is domed are placed. The purpose of these wheels was to prevent mice to reach the stored food and grains. Hórreos were covered with terracotta or slate tiles and surrounded by wooden bars. A room and balcony made of timber sticks were also part of the Hórreo. Hazelnut and corn were dried in the balcony and the room was usually used as storehouse (Ozen and Keles 2008).

2.SERANDER CONSTRUCTION PROCESS

The The sequence of a typical Serander construction was as follows: first, timber posts were erected with a height that is taller than a regular person. The posts were then laterally supported with buttresses or knee-bracing system (figures 1). In sloped terrains, posts were seated on tree trunk bases. There are also circular, wooden or stone headpieces (wheel) that sit on the top of the posts to prevent rats and other animals from climbing up through the structure. Thick wooden beams that carry the main warehouse box structure are placed on the headpieces. The main structure, which is made of 5-7cm-thick chestnut or hornbeam wood planks, is seated on these beams. Serander, is built with wooden masonry construction method (similar to log construction by stacking the structural members horizontally). Timber members are combined to each other primarily by the mortise or lab joints, but corners are joined using scarf joint techniques (figure 5). Since no nails were used in the assembly, Seranders were designed to be disassembled and moved to other villages (Eruzun 1977). The warehouse box floor system was usually constructed as grid shaped, knitted branches of a tree called “Kumar” underneath. Grills for ventilation on the openings of the sidewalls are necessary to circulate air inside the storage box and air circulation is primarily obtained inside the warehouse through this system. The roofing system of Serander is typically built with wooden truss members from trees and designed as a “saddle-headstock” roof (sloped to two sides) or “four shoulder” (sloped to four sides). The roofing material was either wood shingles (Hartama) or fired clay roof tiles (Figure 5). Below the storage box, where the load baring posts stand, not only the tasks like shucking corns, sorting hazelnuts took place, but also woodpiles or beehives etc. were stored. The upper semi-covered section of the Serander is designed

as a balcony, gallery or logia. In some parts of the region, the logia is called "Hayat", and in other parts called "sofa". The logia is usually located at one or four sides of the structure. Corn cobs are hanged, and some foods and pickle jars are stored in the logia. Grinding of flour with a hand mill is also a task that is usually done in that section.

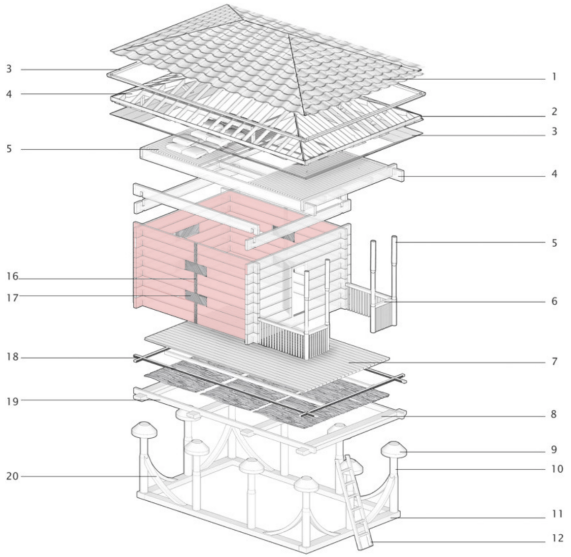
The main space of the Serander is the warehouse box. Peeled corns are stored and sometimes dried there. Some of the warehouses include a half-story floor (mezzanine), where corn clusters and hazelnuts are dried. The warehouse sections are divided into two parts in some Seranders. These are called "two-section Serander". There is a small storage section called "sofa" between the logia and the warehouse in some layouts. In this middle section, corns are threshed, and small spaces or storerooms exist for placing corn, flour, and beans. These middle sections can be observed in the villages of Akçaabat and Tonya. Serander types are categorized among the locals according to their sizes, and the size of a Serander is determined primarily based on the number of its posts. Özgüner suggested a different typology based on the logia/warehouse relation: Seranders with a logia on one side, two sides, three sides, and four sides (ÖZGÜNER 1970). Another size-based typology of Seranders were suggested as small Seranders with four posts, mid-size Sranders with 6-8 posts, and big Seranders with 10-12 posts (Eruzun 1977). The common single-story Serander types are mainly used for drying corn, storing materials and food supplies. They are also used as a guesthouse and/or resting place when necessary. In hot summer nights, people use the Serander to socialize after a long day of work. The function of the guestroom, an important element in Turkish architecture, is provided through placing a room at the ground floor of the two-story Seranders. The ground floor is used as a cellar and sometimes as a storeroom.

Figure 3. Entrance (ornamented) to the box from logia, Muhtar Bey house, Trabzon. Source: (Author 2014)

Figure 4. Corn and hazelnuts inside the storage room, Muhtar Bey house, Trabzon. Source: (Author 2014)

Serander is a special structure that represents the wealth of a village house owner. Because of that, the structure is elaborately ornamented. Beams at the front of a Serander, the entrance door, and the ventilation openings of the warehouse section are also ornamented. The ornamentations are done with wood engraving and hemstitch (auger) techniques. Rims and panels made with geometric and botanical patterns were included. Symbolic examples as pinwheel and star-crescent exist among other traditional patterns. No sufficient information regarding the sources of these wooden decorations and folk architecture exists. It is presumed that the oldest examples in this region were around 200-250 years old.

2.1. Serander elements and assembly process



1. Örtü (roofing material)
2. Ayna (facia)
3. Tavan döşemesi (ceiling slab)
4. Duvar tahtasi (side boards)
5. Balkon direği (balcony post)
6. Korkuluk (railings)
7. Hasir (reed mat)
8. Kiriş (beam/girder)
9. Teker (disk/wheel)
10. Direk (post)
11. Sal bağı (raft knot / wooden beam)
12. Merdiven (ladder)
13. Çita (lath)
14. Mertek (framed structure)
15. Raf (shelf)
16. Kanalli dikme (slotted/ channeled mast)
17. Havalandirma deliği (ventilation opening)
18. Döşeme alti çitasi (slab bottom lath)
20. Çalman / payanda (buttress)

Figure 5. Exploded drawing of the elements of a typical Black sea region Serander. Source: (Author 2014)

1. Örtü (roofing material): The earlier versions of the seranders' roofs were covered in sliced hornbeam tree trunks, called "Hardoma". Trunks were sliced in boards that are approximately 8-10cmx100cm and 1cm thick, then they were overlapped on each other from the sides to the center to cover the roof. Since nailing the hornbeam tree was hard, heavy stones were placed on top for protection from wind effect. Later on, a roof tile material called "Alaturka" (ottoman style tiles) were used. However, low-income families couldn't afford neither wood boards, nor tiles, therefore they reused tin containers after cutting and unfolding it and were nailing them on the roof instead. In order to protect the tin layer from corrosion they coated them with tar. This is the reason why some of the Serander roofs in the black sea region appears black. In the Paphlagonia region (between Kastamonu and Sinop) in both houses and Seranders "kayrak taşı (slate stone)" was used (similar to Seranders in asturias-kalicia regions of Spain "*Horreo*").

2. Ayna (facia): This wood part called "ayna" was nailed for covering the end points of the "Mertek"s (framed structures). Ayna is typically ornamented with wood carvings.

3. Tavan döşemesi (ceiling slab): Above the ceiling of Serander was never completely sealed with wooden slabs. When viewed from inside upwards roof Merteks (framed structures) can be seen. The roof beams stretch from the sidewalls only about 80-100 cm (like a big shelf) in order to use that space as a storage or for drying fruits. These shelfs are also called "Caçel, Tarzel or Tarcel" in the town of Rize.

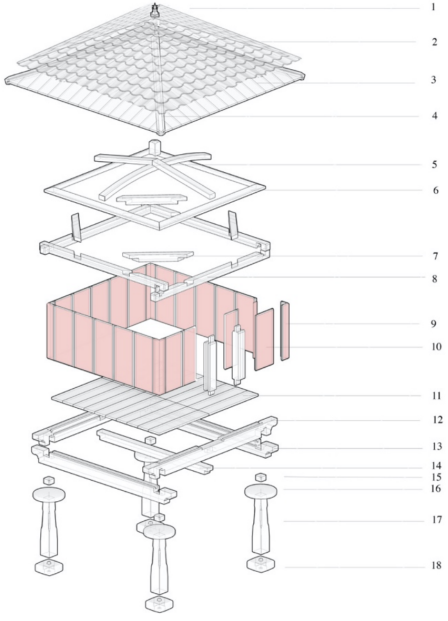
4. Duvar tahtasi (side boards): Almost all around the Black sea region interlocking wood parts by notching their head parts is called "Boğaz (throat-interlock)" (boğaz serander (throat/interlock serander), Boğma Serander (jamming/throttling Serander)).

5. Balkon direği (balcony post)

6. Korkuluk (railings): Usually railings are between 50-60cm high.

7. Misir odasi (corn room): The room floor (ground of the serander room) is covered with chestnut tree wood (no space between woods) in artvin, rize and regions of trabzon close to rize (sürmene). In this case the ventilation openings should be enlarged. On the other hand, in other regions the ground of the serander room is covered by 1cm spacing between wood parts in order to allow air circulation.
8. Kiriş (beam/girder)
9. Teker (disk/wheel)
10. Direk (post)
11. Sal bağı (raft knot / wooden beam): wooden beam is called "sal bağı". The name comes from the vehicle raft. As the raft carries the load upon it, the "sal bağı" carries the load of the Serander.
12. Merdiven (ladder)
13. Çita (lath): No matter what is used as roof covering, in order to attach the covering to the roof laths are nailed (like laths under tiles in modern architecture).
14. Mertek (framed structure): elements used in roof frames and structure are generally called "Mertek".
15. Raf (shelf)
16. Kanalli dikme (slotted/channeled mast): head parts of the side boards from both sides are penetrated into the channel opened in this mast.
17. Havalandirma deliği (ventilation opening) these grilled windows are placed on four sides of the warehouse box. These openings allow air circulation in order to ventilate and dry the corns inside. The patterns of these openings vary in different regions.
18. Döşeme alti çitasi (slab bottom lath)
20. Çalman / payanda (buttress) In modern architecture it is called Payanda (buttress). However, in many places in the Black sea region it is called "Çalman".

2.2. Hórreos elements and assembly process



1. Moños (Bows cover)
2. Tejas (Ceramic roof tiles)
3. Cabrios (rafters)
4. Aguilónes (Vertices Beams)
5. Vigas del queso (curved tie rods)
6. Orilleros (end beams)
7. Gatos (corner bracing)
8. Liños (decorated head beam)
9. Engüelgos (Box Bracing)
10. Colondras (decorated vertical wood planks)
11. Pontes (floor wooden planks)
12. Trabe superior (upper floor beam)
13. Trabe durmiente (lower floor beam)
14. Sovigaño (central bridge beam)
15. Tazas (square wooden levelers for the main beams)
16. Muelas (stone disks or squares/ post head/rodents shield)
17. Pegollos (posts wood, stone or masonry)
18. Pilpayos (column isolated base/ slab on grade)

Figure 6. Exploded drawing of the elements of a typical Spanish Hórreos. Source: (Author 2014)

1. Moños (cantapaxarinos, obispos): The bows, besides fulfilling an aesthetic function, are the finishing pieces that cover the cuts of the tiles or the zenith slates to avoid a possible entrance of water. They are generally formed by two stones, a slab that can be square, round or irregular, placed horizontally and over it a stone more or less conical or pyramidal. There are also ceramic bows in the form of pinnacles that adorn some granaries built in the first half of the twentieth century.
2. Tejas (teyes, teas, teichas, techas, teixas): Tejas are the ceramic roofing tiles that shed water from the roof. The tile traditionally used in hórreos is the curved tile, known as "Arab tile". Also original is the flat tile of industrial manufacture (Asturian pottery of San Claudio, Guisasola ceramics), used in some hórreos and Paneras. The old Arab tiles better protect the roof from wind force uplift because they are heavier, as well as the frost, since their resistance is guaranteed by the years that they are exposed to the elements.
3. Cabrios (cobrios, quebrios, clabios): Cabrios are rafters that form the roof surface. They are nailed with lathes to the burrows and embedded in the watering of the gables. They typically varied in width and have a thickness of between 3.5 and 5.5cm.
4. Aguilónes (aiguilones, aguiles, aligues, anguilones, aquilones): Gables are the beams that define the vertices of the roof in granaries and Paneras. They are placed on the plane, anchored in the insertion of the burrows and connected to each other or to the ridge at the top. They have a longitudinal watering on their two lateral faces, where the heads of the cabrios are inserted. The section of the gables oscillates between 16 x 10cm and 25 x 14cm. The positioning of the gables defines the eaves length and the percentage of inclination of the roof, this can vary from 30 to 40% slope for Arabic tile, and between 40 to 60% for slates. The length of the eaves can vary between 60 to 120cm.
5. Vigas del queso (perros, crucetes): These are two pieces of rectangular timber section, typically curved, to make tie rods in order to counteract the horizontal pushes of the cover and thus avoid the bulging of the lines. In Paneras these beams also serve as support for the pairs that hold the ridge. Its diminsion oscillates between 12 x 10cm and 22 x 15cm.
6. Orilleros (orelleros, agueros, aguaderos): Orilleros are the members that cross the eave perimetral and are typically attached to the ends of the Cabrios.
7. Gatos: Gatos are the bracing members that hold the warehouse box avoiding possible deformations. Gatos are not essential pieces in the granaries, but they are useful to serve against lateral forces.
8. Liños: These are rectangular section beams smaller than the Tabes, that fit on the Colondras and joined using a lab joint. In some cases, Linos are decorated with carvings and paintings, it is common that the heads of the files are carved. Its section is variable, oscillate between 9x14cm to 18x32cm.
9. Engüelgos (embuelgos, engüelbos) Engels are the pieces that form the corners of the box. They are usually made in one piece in the oldest hórreos or made from two Colondras nailed. The swivels give the box stability against possible lateral stresses and have the same thickness and length as the Colondras.
10. Colondras (colondes, corondies, curondes, curondies, cureñes): The Colondras are rectangular planks, with its exterior face carved, that arranged in vertical position conform the box of the granary. On some occasions the Colondras have carved or painted decorations, as well as decorative and functional vents. Its length vary from 100cm in the oldest granaries to 160cm in the most modern. They are made in varied widths, depending on available timber. The thickness oscillates between 4 to 8cm.
11. Pontes (pontis, puentes, puontes, puöntis): Floor planks are found in the oldest granaries and Paneras and are formed by timber boards of varied widths from 6-12cm.
12. Trabe superior (madres): Trabes are the main girders that support the Hórreo load. They do not necessarily have to be straight in

their horizontal face, since typically they take the form of the trunk from which they were sawed. They are joined together by a lab joint. The inner faces of the two longer girders have a length of approximately 6 x 6cm or 7 x 7cm in which the heads of the bridges are arranged. The girders have to span between 3 to 5 meters and their section varies from 16 x 25cm to 25 x 40cm.

13. Trabe durmiente (madres) secondary girders or beams

14. Sovigaño (alcarcelera, carcelera, sobregañu, sobrigañu, sobregaño): Sovigaño is a beam that is centered in the frame which prevents the deflection of the bridges, or, in case the floor is made of boards, There are cases in which, for this same function, two or more overlaps are used. Although it is a piece that is not essential, in most cases it is necessary. The section of the Sovigaño can be square or rectangular and oscillates between 12 x 12cm to 20 x 20cm.

15. Tazas (taces, mollideros, mullideros, tacos, tocos, tecos): A square-shaped prismatic wooden blocks that are placed between the wheels and the girders (chairs), used to level the frame, as well as centering and damping the weights on the wheels. Its dimension oscillate between 12 x 12 x 3cm to 20 x 20 x 12cm.

16. Muelas (mueles, pegolleres, pegulleres): Muelas are stone slabs (rarely made of wood) of square, round or irregular shape, that are placed horizontally on the Pegollos to avoid the access of animals and rodents to the granary or Panera. Its measures oscillate between 60 x 60 x 7cm to 80 x 80 x 20cm.

17. Pegollos (pegullos, peollos, peullos, pigollos, piollos, pegoyos, pigochos, piales): Pegollos are the columns/posts that support, balance and level the granary. Depending on the areas and the antiquity of the construction, they can be made of wood, stone or masonry bonded with mortar of lime or clay.

18. Pilpayos (pilpaños, soleres): Pilpayos are the slabs on which the whole weight of the Hórreo rests on, their function is double, since in addition to cement, they avoid the access of the humidity of the ground to the Pegollos. Its surface dimensions are always greater than the base of the Pegollos and its thickness can never be less than 12cm.

3.SIMILARITIES OF TYPOLOGIES AND CONSTRUCTION METHODS

It is evident that when studying the construction, proportions and materials of traditional architecture, we can realize the simple yet complex machines these objects are; how everything has a reason to be and nothing is superficial or meaningless in them. These folk structures share not only construction, material and form features, but also the areas where they can be found have common climatic and geographic conditions despite the physical distance (Rodríguez, G. G., & Velasco, S. A. 2013). General elements of both Serendars and Horreos can be summarized as the following:

1. Foundations: Drying sheds built in stone needed more carefully planned foundations than wooden ones since they were heavier, but despite this fact, they all must have a solid support.
2. Feet (Posts): They were built in wood or stone and shapes typically varied from circular to square and rectangular. They were conceived as pillars and appeared in different even numbers depending on the size of the drying shed and the style it is built in.
3. Corbels (post capitals): Pillars were typically capped with stone or wooden slabs (wheels/disks) where beams later rest on. These slabs were larger than the columns and beams they serve, and it was because they prevented animals and rodents from reaching corn and hazelnuts. Corbels are structural elements and protection devices at the same time.
4. Grill (matt) This subfloor ventilated layer allowed air to flow around the warehouse box removing high levels of humidity

and allowing constant air replacement. It prevents moisture to reach the storing chamber and acted as a natural barrier for rodents to access the maize.

5. Warehouse (box): The floor system always laid on beams set on top of the structure supports and can vary in size as well as in layout. The first case is the most primitive type and reminds of big knitted baskets in atruncated cone shape with irregular openings all around its perimeter.
6. Roof: In the earlier versions, roofs where movable as the warehouse was loaded from the top. Every year straw was replaced as it didn't keep its properties longer, and the drying shed was loaded with a new crop. Later on, it became a stationary roof as straw was replaced by more endurable roofing materials and an access on the walls was opened for loading maize.
7. Stairs (Ladders): were typically built next to the construction as a separate object. They were never connected to the upper level and the void left corresponds to human dimensions and proportions, preventing rodents or snakes from reaching crops. Sometimes, removable ladders were stored somewhere else when not needed, or stationary isolated steps designed for human proportions.

4. COMPARISON OF ELEMENTS

The warehouse box structural assembly and construction techniques developed in the mountainous region of the Iberian Peninsula of Spain is fundamentally different than the one developed in the Black sea region of Turkey. While both structures utilized timber board single wall approach, the timber boards in the Horreos were assembled vertically, however in the Seranders were assembled horizontally, similar to timber log construction techniques. The Turkish horizonal arrangement of the single wall boards allowed the development of the resilient corner lap joint which provided the box with more structural stability at the same time the flexibility to cope with seismic forces (the Black sea region have been prone to earthquakes and seismic forces). It could be argued that the corner lab joint was developed as a result of similar techniques that could be traced to timber log construction in the region, similarly assembling the timber boards horizontally could be traced to ship and boat building traditions in the region given the proximity to the sea. The vertical board assembly in the Horreos however were developed without a lab joint at the corners and therefore the box was prone to lateral forces. The examination of many timber Horreos documentations revealed that the majority of structures lost

stability due to earth and wind movements. It could be argued then that the warehouse box typology although seemed similar in both countries, they astonishingly differ in their structural and architectural approach. As seen in figure 7, The development of the corner in Seranders allowed for a sophisticated tectonic expression through the elements and wood carvings. An elaboration of the importance of the structure to folk and vernacular architecture. The following observations could summarize the study findings:

1. These warehouse box granaries structures in Turkey and Spain were prosperity indicators, prestige structures in the cultural life of the two countries. These separate structures served as guest houses, food, and valuables were stored and dried, entertainment and resting activities took place.
2. Both of the two structures were constructed to store grains, and host guests nearby the rural house.
3. Both of the structures were constructed with hybrid wooden and masonry techniques. Loadbearing posts, single wall timber box, and roof systems were similar, however structurally different as explained, and therefore, both could easily be demounted, diss-assembled and transported.
4. Both of the structures had similar sections. Storage-warehouse box, free standing posts with wheel capitals, and a Logia in front or all around were common elements in both structures.
5. The elaborate ornamentation with wood engraving technique or paintings were originated from the importance given to them. However, it was more developed in the Turkish example.

CONCLUSION

It is known in the architecture history, especially vernacular architecture, that in similar physical and environmental conditions, similar architectural language and vocabulary are created. Warehouse structures typology found in the country sides of Scandinavia, the Iberian Peninsula, and the Black sea region shared a simple yet sophisticated elements of architecture that were born out of necessities. The two compared examples offered in this study namely Serander in Turkey and Horreo in Spain, while both seemed similar in their structural techniques, a deeper investigation on the box single wall structure revealed a fundamental difference in dealing with lateral forces. It is possible to argue that the geographic timber craftsmanship that were developed in the Black sea region were a major influence in more resilient warehouse box structure that coped with seismic movements. A construction technology that issurprisingly absent from the Iberian Peninsula type. A series of similarities can be seen between the Eastern Black sea region and the Iberian Peninsula life and folk architecture depending on the natural environment. Similar geography and living conditions ended up with creating similar solutions. Great similarities were observed in the economic activities such as: the construction techniques, house and agriculture tools, animal breeding, hunting, and forestry. Similar living styles, structure design and techniques were produced by this way. When the fundamental structures of vernacular and folk architecture are considered, there are functional similarities between the house, the main living unit, and subsidiary structures as barn and hayloft. As throughout Turkey, specifically in the Eastern Black sea region, the structures of folk architecture such as the Seranders were not researched in detail and cannot be protected at sufficient levels. Village houses and Seranders should be researched in detail and necessary protection works should be done in specific to Eastern Black sea. Changing social and economic conditions, migration to cities, and abandoning corn farming have left the old houses and Seranders empty. These empty and uncared structures are demolished and disappeared rapidly. It is an important mission to protect and cherish these unique structures of the folk architecture as architecture works, artworks, and historical places.

ACKNOWLEDGEMENTS

This study was conducted during an extensive travel throughout the Black sea region of Turkey in the late summer of 2014. The author is grateful for the immense help of Mr. Mustafa Mustafaoglu and Mr. Ali Mustafaoglu for their friendship, guidance and support in traveling across the Black Sea region of Turkey. Sincere gratitude also goes to Mr. Atalay YILMAZ for his elaborate explanation of the terminology of Seranders in Turkish language, and Nancy Al-Assaf for her assistance with drawings.

BLOCK 7: NEW PROFESSIONAL PRACTICES AND RESEARCH PRACTICES

PAPER #7.01

DESIGN FICTION AND ARCHITECTURE

Philip D. Plowright[a]
[a] Lawrence Technological University, Michigan, USA

ABSTRACT

Design fiction is a design approach emerging out of the formal disciplines of Industrial Design and ubiquitous computing (Dourish and Bell 2008, Bleecker 2009a, Grand and Wiedmer 2010, DiSalvo 2012, and Sterling 2013b, 2016). Other design fields are starting to consider the value of this approach, including architecture and urban design (Knutz et al 2014). However, it might be claimed that both architecture and urban design have long involved the production of fiction and fictional environments in their pursuit of novel or aspirational project outcomes. The architectural design ideas competition can be traced back as far as the documented history of architecture – at least two and a half thousand years (Kreiner 2010, Lipstadt 1989) – and has been focused on reimagining our built context through visionary futures. Architectural environments are a staple in media representations of future-orientated imaginings. All design can be defined as exploring possible futures through formal outcomes as the products of a design process do not yet exist but will possibly come into being. This begs the question of a more precise understanding of design fiction and its role as both a positioning approach as well as a methodology for its use in architectural design. As such, this paper examines the nature of design fiction and reveals its close relation to a group of design approaches related to future-forecasting but also the growing consolidation of its definition through a design research structure, recurrent method frameworks, the translation of literary tactics and focus of diegetic environments.

KEYWORDS

Architectural fiction; design fiction; diegetic environments; rhetoric; design research.

INTRODUCTION

Design fiction is an emerging approach that has developed out of several independent sources (Sterling 2005; Dourish and Bell 2008; Bleecker 2009a) and, while reaching some level of agreement, remains somewhat ambiguous in its definition and application (Barbas 2017). While the approach has its origins in product design and ubiquitous computing (ubicomp) through science fiction representations of technological artefacts in literature and film, it has been connected with all of the formal design disciplines including architecture (Knutz et al 2014). The current, and oft quoted, definition of design fiction given by science fiction author Bruce Sterling is "the deliberate use of diegetic prototypes to suspend disbelief about change" (Bosch 2012) stressing *plausible futures* rather than proposed futures. There are various interpretations of what exactly this means in application. Other theorists have expanded or restated the Sterling definition, describing design fiction through "narrative elements to envision and explain possible futures for design" (Tanenbaum 2014b), the use of world-building and prototypes within those worlds to produce a discursive space (Lindley and Coulton 2015) and "a conceptual design placed within a broad cultural context focusing not just on product functionality but potential social consequences of use" (as quoted in Blythe & Encinas 2018, 16).

While the various definitions introduce some nuances, there is a general agreement of key concepts needed to be present for an approach to be defined as design fiction. These are *diegetic artifacts present through narrative structures* (Bleecker 2009a; Sterling 2013a), the suspension of disbelief in near future forecasting (Girardin 2015) and understanding artefacts as *socio-technical representations* rather than simply technical objects (Bleecker 2009a; Dourish and Bell 2014). Each of these concepts need unpacking a little to clarify their effect and importance as part of the overall approach. Diegetic is a term imported into design theory from film studies and refers to something that exists within the world of a narrative rather than external to that world. A simple example is the difference between music playing on a radio in a film versus the overlaid score that builds an emotional tone. The former is diegetic as it is heard by the characters and embedded in the narrative – it exists in the narrative world. The latter is not diegetic as it is heard only by the audience is not part of the narrative world. For designers, then, a diegetic prototype is a "kind of techno-scientific prototyping activity" embedded in "a story into which the prototype can play its part in a way different from a plain old demonstration." (Bleeker 2009a, 39) The prototype, the designed artifact, is explored by its presence in the narrative through subtle interactions with narrative elements rather than presented as a discrete and independent to its surroundings. In this, a diegetic artifact is very different to traditional design visualization tools such as sketches, renderings, product placements, or presentation boards as the designed object is not the focus but there to move "the story forward while at the same time subtly working through the details of itself." (Bleeker 2009a, 39). The presence of the diegetic environment requires logical consistency – even if we don't know exactly how things might work, the artefact must present its operation as defined through the internal logic of the narrative (Tanenbaum 2014a).

The purpose of the diegetic prototype is the suspension of disbelief for a plausible future as an extension of reality rather than the production of fantasy. In this way, design fiction is a form of realism which "implies self-consistency in both the real world and the story world." (Kirby 2010, 46). It could be said that all design activities engage future conditions as designers envision objects and environments that do not yet exist in the particular context, composition, adjacencies and relationships of the proposal. However, design fiction is focused on the plausible rather than the probable as one type of possible future (Hancokc and Bezold 1994). Fiction, in this case, is not a form of speculation and, therefore, design fiction includes the intention to produce valid knowledge in a structured way as part of design research (Grand & Wiedmer 2010; Markussen & Knutz 2013). This shifts the purpose of design fiction away from being a creative technique, a tactic of divergence which allows an author to imagine a world that does not yet exist, to be instead a legitimate research method.

While design fiction prioritizes the technological, the diegetic artifact is co-created with the socio-cultural context in which it exists which makes the artifact a *socio-technical representation*. There are two effects of this relationship. First, the artifact is co-dependent on the social values, social identity political, ethics and morality of its narrative context as well as the interactions, beliefs and construction of social expectations for the users or occupants. Design fiction makes visible a fundamental fact of design: namely there is no way to separate a designed object or environment from its context as all applied design is situated. As Bleecker (2009a: 76) states, "the implications of culture are not something that happens after design. They are always part of the design". Second, the role of the artifact as an aspect of socially constructed knowledge and the construction of belief

systems allows an entry point to influence those belief systems. The fictional world, and its elements, is a persuasive rhetorical device as it "has taken the time to take user experience and technology seriously" (Tanenbaum et al 2016, 4). This introduces a point of tension into the theory as defining design fiction as a research method is epistemologically in conflict with understanding design fiction as an agent in changing values and perspectives - shifting what we believe in or what we desire to bring into being or, as Bleecker names it, an "epistemological wrench" or "swerving systems of meaning" (2009b). The interaction or conflicting purposes between these two aspects of design fiction are not well resolved or even identified in the theoretical literature.

This paper expands on the points above to consider design fiction as a possible approach for architecture. This includes its relationship to other discursive design approaches as well as the design tactics and general frameworks used to generate outcomes. The examination brings more clarity to design fiction while generally considering its application to architecture as a formal design discipline.

1. CLARIFYING THE THEORY

1.1. Discursive design and its variations

The term *design fiction* came into its current meaning through a seminal essay by Julian Bleecker of The Near Future Laboratory (Bleecker 2009a). It was this essay that positioned the approach as having a socio-technical focus, stressing the diegetic nature of the artefact and its role in influencing human belief systems. Previous to this, the term design fiction had been used by Bruce Sterling (2005) and, even earlier, Sterling introduced the term *architectural fiction* to refer to the production of built environments for use in narrative construction (Sterling 2003a). As discussed below, architectural fiction and design fiction differ in definition and theoretical approach although they both belong to a group of design practices labeled as discursive design (Tharp and Tharp 2009, 2015). These include, along with design fiction, critical design (Dunne 2005), forecast design (Buhring & Koshkinen 2017), and speculative design (Auger 2013). Discursive design approaches are part of a social constructivist epistemology and can be defined as design research since the result is the generation of knowledge as an outcome rather than production of a product. Being social constructivist in worldview, discursive design practitioners and researchers are primarily focused on the interrelationship between technology, designed artifacts and socio-cultural interactions where the ability to treat artifacts as isolated and inert objects is impossible.

The primary purpose of discursive design practices is "to communicate ideas [and] encourage discourse. These are tools for thinking; they raise awareness and perhaps understanding of substantive and often debatable issues of psychological, sociological, and ideological consequence" (Tharp and Tharp 2009). These operate through provocation, production of uncanny situations or uncomfortable reflection (critical design) but also through narratives using a story or fictional situation (Auger 2013, 4-5). The differences between these practices are quite subtle and often do not operate with strict boundaries. A discursive project might align with several approaches although each practice has its differences in intention, cognitive tactics (i.e. the major tool in their method construction) and approach to epistemology.

Critical design, for example, is used to challenge social expectations and generate a debate focusing on current concerns by using a designed artifact in the same way as "a critique, like a political essay or satirical sketch" (Blythe & Encinas 2018, 12). It uses design outcomes, specifically product and industrial design artefacts, as a way to probe and interrogate social practices and values with a focus on consumer culture (Tharp and Tharp 2009). The

driving question for critical design is: we can do this, but should we? As such, critical design is focused on the present and uses satire and the uncanny as major design tactics.

Forecast design is intended to engage preferable futures rather than the *plausible futures* that is the focus of design fiction (Buhring and Koskinen 2017). While both forecast design and design fiction are concerned with the near future, the purpose of forecast design is to predict what might happen considering current trends. Design fiction, on the other hand, is not engaged to predict a future but to create a future that would not normally manifest, to influence through the design fiction outcomes. The alignment is closer to critical design than forecast design, but less as a critique of social ethics but "to spark conversations about the near future, check the sanity of visions and uncover hidden perspectives" (Girardin 2015, 7).

It is speculative design that is often confused with design fiction (Auger 2013). Kirby makes a clear separation between the two through a discussion of the role of diegetic prototypes in contrast to speculative scenarios. He considers a speculative scenario to

> "represent highly implausible and impractical situations and technologies that film-makers and science consultants imbue with a sheen of plausibility, so that they look possible within a film's narrative. They make these technologies look plausible, knowing that they are impossible to achieve in real life. In contrast, technological advocates who construct diegetic prototypes have a vested interest in conveying to audiences that these fictional technologies can and should exist in the real world." (2010, 46).

This definition would consider speculative design as producing daydreams, fantasies and imagining for pleasure. Speculative design does not require the internal or narrative logic to be aligned with perceived reality. In the end, the results of a speculative exploration have no requirements or possibility of coming into being. As such, these technological fantasies, while seeming possible, are not engaged to build desires – i.e. they lack the epistemological focus of design fiction (Bleecker 2009a). In addition, speculative design might suggest possible futures but as interesting explorations. Design fiction, in contrast, is positioned as a critical research tool. The outcomes of design fiction are understood as experiments to return usable information through a design approach (Grand and Wiedmer 2010; Markussen & Krutz 2013; Krutz et al 2014; Coulton et al 2017).

1.2. Design fiction and architectural fiction

One of the difficulties in clearly defining the role and application of design fiction is the presence of a similar, but significantly different, term presented through popular media outlets. Before design fiction entered the lexicon, the term *architectural fiction* had already been coined in a blog post by Bruce Sterling (2003a). Sterling, a science fiction author, expounded on the lost potential of Archigram as a form of a fictional future. In a series of magazine and blog posts, Sterling drove the idea of architectural fiction single-handedly, adding Greg Lynn FORM (Sterling 2003b) and Lars Spuybroek (Sterling 2008) as his inspirations. The role he envisioned for architecture was not meant for architecture though, nor did it have the intentions to be either an epistemological device or a research tool. Rather, as Sterling (2008) writes, "Want to write a novel? A screenplay? An essay about landscape and climate change? Want to direct a music video? Start a blog? Architecture offers fuel – and amazing visuals – for all of these things". In this, Sterling is acting as a voyeur, using architectural visualizations of possible future built environments driven by technological developments to "world build" as an aid for writing.

There is a version of Sterling's architectural fiction that can be found historically within the architectural discipline. This is the ideas competition and speculative design project

which can be traced back as far as the documented history of architecture (Kreiner 2010, Lipstadt 1989). However, it has been noted by critics such as Jeremy Till that the architectural competition focuses on the building "as static object … It privileges a whole set of architectural values that are counter to what might make really great architecture" (Hopkirk 2013). In this, the focus is the *representation* of building form rather than the social effects that trends towards utopian and deterministic outcomes. In recent decades, the idea competition is closely tied to imagining complete environments based on speculating technological changes – although we could argue that most of these changes manifest at the urban or architectural engineering levels through technological line-items rather than through architectural knowledge. Regardless, we can clearly define this approach as discursive design, although it lacks the polemical and epistemological purpose of design fiction. Rather, it is a form of speculative design connected to technological utopianism. What is important about the clear excitement of Sterling when he discovered for himself the possibilities when considering the design of human environments is that one must "realize that architectural projects, by definition, entail the reimagination of how humans might inhabit the earth – how they organize themselves spatially and give shape to their everyday lives" (Sterling 2008). That is, architectural design inherently involves social and cultural content. However, architectural fiction as a form of speculative design does not have the structure or intentions to critically engage this architectural content as it lacks epistemological and research focus aligned with socio-technological environments. In contrast, Varnelis uses the term architectural fiction in alignment with the theoretical framework of design fiction rather than the form-based speculative worldbuilding of Sterling. Varnelis wonders if there is a possibility for architectural fiction to be a critical design tool that, "Instead of being Utopian or imaginative, might it be possible for architecture to shape our experiences in such ways as to approximate the effects of films or fiction? […] could architecture fiction be something that re-shapes our subjectivity?" (Varnelis 2009a) It is exactly this subjectivity that Bleecker addresses when he considers the core application of design fiction to be the shifting of human belief patterns and desires through swerving systems of meaning (2009b).

2. THE COGNITIVE STRUCTURE OF DESIGN FICTION

2.1. Process actions, tactics and tools

While there is some consolidation of theory that forms the boundaries of design fiction, there are very few discussions of the methods used to do design fiction. Methods, in general, are difficult to discuss as they are generated from the assemblage of tactics within a framework based on situated needs. This makes methods fluid and operating with great variation depending on context but also suggests that considering frameworks and tactics is ultimately more useful for designers.

2.1.1. *Frameworks*

A framework is the intellectual super-structure to which the overall form of any situated method is aligned and provides the starting position, restricts the information to be considered and provides the major testing criteria. In the case of design fiction, the frameworks are identified through the relationship to future-forecasting and notions of plausibility. The major frameworks present are *extrapolation* and *speculation* (Bleecker 2009a; Hales 2013; Bell and Dourish 2014). As Bell and Dourish note, "extrapolation and speculation as the twin bases for the production of science fiction, and which we would argue applies also to the ways in which design-oriented research is typically carried out, with an explicit focus not only

on the extrapolation of current technological opportunities, but the imaginative and speculative figuring of a world in which new technologies can be applied." (Bell and Dourish 2014, 2). However, to meet the requirements for design fiction – near-future siting, alignment with realism, plausibility rather than possibility, epistemological requirements of belief shifting, and the production of valid knowledge – speculation, in this case, cannot mean free-form and fantasy-based imagining (Bleecker 2009a). Extrapolation is based on the question: this is what we have, where does it go? It is the action of determining a future or end state based on assuming that the existing trends will continue without deviation. While the common use of extrapolation is predictive (i.e. logical future conclusions or outcomes), in design fiction extrapolation is used to explore possible alternatives (Girardin 2015). Bleecker calls this process developing "fiction from fact" (Bleecker 2009a). Lindley and Coulton reinforce the presence of extrapolation when they present a three-layer model that moves from a reality layer of the "world today as particular sets of users may know it" (2014, 2). The reality layer as source material is critical as it is used to contextualize all other information in the design fiction development. As a framework, extrapolation anchors any methods firmly into factual information present in the current environment as the starting point of any design work. The nature of design fiction would also stress that information be based on socio-technological factors. Speculation is the second framework present and it is easy to misunderstand its application in design fiction. The general definition of speculation is the act of forming a theory without facts, proof or firm evidence with "a strong leaning towards conjecture" (Auger 2013, 2). Usually, there is little concern if the generated ideas are real, defensible or "contained by the rules of real life" (Auger 2013, 2). However, design fiction *requires* the construction of plausibility with the focus to produce valid knowledge – a goal that conflicts with the general application of speculation if pursued as the production of identifiable false and fantastical scenarios. Bleecker provides clarity to the use of speculation as a framework that aligns with design fiction through an operation he refers to as "facts from fiction" (2009, 26). Rather than forming a theory without facts, speculation in design fiction operates as forming a theory (design idea or possibility) *before* facts. Open speculation of near-future possibilities ('fiction') is possible but then requires the generated idea to be anchored back into current reality and factual knowledge with the intention to make the speculation seem believable or obtainable. This is accomplished by tracing the speculative idea from the future backwards to possible ways that idea might come into being. Design fiction speculation is more complex than "what-if" scenarios we find in speculative design as the latter requires little expectation that the scenario has any relationship to current reality (Markussen and Knutz 2013, 233). Speculation in this form produces the question: this is where we want to go, how do we get there?

2.1.2. *Tactics*

A tactic is an action performed as part of a method. There are limited tactics discussed in the design fiction literature and those referenced are often standard design tools such as sketching, building models and mood boards as well as research methods such as ethnographic and behavioral mapping (Grand and Wiedmer 2010). While this might suggest that design fiction has nothing to add to the "toolbox" for generating design outcomes, there is one fact that is important to recognize: design fiction engages socio-technical information to understand the designed artifact as an active agent within the situated context in which it exists rather than an inert object. The approach does not allow an architectural designer to limit their values and decisions to only formal consideration for physical aesthetic decisions of shape-to-shape relationships. At the same time, the traditional

tactics of architecture – environmental force identification, program resolution, cultural identity through elevation, massing variations – that visualize architectural decision making do not allow access to the type of information that design fiction engages. There are tactics found in other design disciplines and literature practices that can be imported into architecture. One tactic found in design disciplines such as product design and UX/UI that directly addresses human interaction with designed objects is persona construction. A persona is a construct – we might think of it as a character against which design decisions are tested.Architecture does not normatively construct persona to determine formal choices although it could be argued to be aligned with the abstracted sense of client needs and desires formalized through a project brief. The architectural version, however, lacks a direct connection to a larger scenario or narrative construction required for design fiction. Personas have been criticized as being a representation of the designer rather than a tool of empathy as well as often "two dimensional and stereotypical" (Blythe and Encinas 2018, 17). Through design fiction, however, the persona is linked directly with "narrative voice" (Burdick 2019, 85) which requires a much deeper understanding of the motivations and actions of the user. While in other design approaches, the persona might be connected to a mood board, journey map or other visualization tool, in design fiction the persona is directly involved in the construction of scenarios and then used to "predict the goals or actions of users" (Blythe 2004, 52). Scenario construction is a key element in design fiction, and it is the interaction between persona/characterization and scenario construction that makes design fiction a research tool.

A variation of persona and scenario construction is the tactic of *pastiche scenarios* developed to address limitations in both the former. Pastiche "is a form of writing that imitates and borrows from other works and styles" (Blythe 2004, 52). When applied in a design fiction context, the designer uses previously existing characters, locations and events to develop persona and scenarios for the project. As the persona was not created for this particular design context, it introduces more richness and complexity to motivation as well as disconnects the persona traits from the expected or desired functionality of the designed artifact (Markussen and Knutz 2013). Examples of pastiche scenarios is using favorite characters of a novel as the clients of an architectural project or using an author's literary style to produce a design context. The pastiche tactic allows a designer to "very quickly evoke resonant contexts in which to place a new design or consider user needs" (Blythe 2004, 52).

Another literary tactic proposed to have relevance in design fiction is tropes. Tropes "are figurative language such as metaphor, irony, or hyperbole [that] convey an idea through terms and structures that are not literal, but rather symbolic" (DiSalvo 2012, 117). Although DiSalvo mistakes the operation of literary metaphor as equivalent to conceptual metaphor, the theoretical basis has some validity. These literary devices can be used to create a meaning "scaffold" through associating two domains of knowledge where the first provides a reference to the second. Examples could be presenting food production as a type of politics, grocery shopping as urban hunting or dinner parties as combat environments. While these are not metaphors as there is no incongruence in the association (i.e. food production does involve politics, grocery shopping is a type of food gathering), they do provide a reframing of the source material that allows us to reveal associations that are normally suppressed or obscured through societal norms. What the trope does is open up "expressions of values" (DiSalvo 2012, 117) and shifts the point of focus to consider the social implications rather than physical object. Bleecker suggests that tropes are involved in the anchoring of facts to fictional ideas as part of speculation (2009a, 15).

2. 2. Design fiction and the frame

The framing and presentation of the designed artifact is a key factor in design fiction, an aspect that makes it distinct from other forms of discursive design, and a factor that makes its use in architecture difficult. While other discursive design approaches celebrate their outcomes, producing spectacles, fantastical worlds, uncanny apparatus and strange curiosities, the artifacts that design fiction introduces are "mundane" (Girardin 2015, 2); everyday objects and spaces that are unspectacular (or anti-spectacular). Design fiction uses "real-life delivery methods" (Auger 2013, 10) that deny the existence of a frame between the object and the viewer through creating an ambiguity if the designed artefact, space or event exists or not. It is that moment of unsurety, of second guessing, which makes design fiction effective. The role of the approach is not to criticize, challenge or comment on society (that is critical design). Instead, its application is to examine possibilities in near future narrative scenarios to test if that scenario is one that we wish to bring into being and, if so, to introduce desire towards those things proposed to be present. The diegetic nature of design fiction requires an artifact, and the built environment is an artifact, to exist within a larger narrative structure. However, the artifact is not the focus of the narrative, it simply exists to support larger socio-technical interactions engaged as an act of everyday life. This process merges what is fictional with what is factually reality in a "knotting action" (Bleecker 2009a, 25) and suppresses the frame where constructed narrative is ambiguously located. The choice of media representation becomes a key aspect in the design fiction methodology and why practitioners of design fiction, such as Bleecker, Girardin and Near Future Laboratory (NFL), produce "catalogs, newspapers or user manuals from the future" but also "unboxing videos, user reviews" (Girardin 2015, 3). These media strategies are typologically normative and expected in our current reality so allows the framing of a fictional artifact in such a way to suppress the visibility of that frame. However, these media strategies are non-normative in architecture and introduce a point of difficulty in applying the approach successfully.

CONCLUSION

Design fiction is one of several approaches found within discursive design. The key differences between this and other discursive approaches center on 1) the ambiguity of the designed artifact existence as fictional, 2) the presence of the designed artefact as part of a larger cohesive narrative and 3) the desire to use the designed artifact and its scenario to test and shift belief systems. While some speculative designers also believe that it is "preferable for the concept to pass as real," (Auger 2013, 9), one could argue that speculative design that attempts this should be understood as a form of design fiction. At the same time, the purpose of design fiction is not fiction, which seems counter-intuitive. Rather, it is to return knowledge or affect beliefs.

Design fiction has several benefits but also introduces some difficulties for architecture. One benefit is the prioritization of the relationship between the user and the artifact. In the architectural design process, this means that attention moves from values that support the idea of a building or environment as a static sculptural object to those that are focused on the possible social and emotional positioning of its constituents. Environments are then understood as active participants in those social interactions. A second benefit produced by the shift in focus is the required abandonment of the notion of 'problem-solution' framing for design. As a research approach based in the interrelationship between humans and their constructed technological artifacts, design is understood as a situation to be acknowledged rather than a narrow problem-solution conceptualization.

The role of the persona and scenario tactics reinforces broad, and often contradictory, responses to the same design artefact as a reflective tool for designers.

Finally, the factors that design fiction provide as benefits can also introduce difficulties in architecture. It is easy to consider a building or built environment as a type of sculptural object. It is also relatively easy to consider engineering products as 'cool' features in buildings or even to imagine some non-existent technology that might be integrated into built space. However, based on our current toolset, it is much more difficult to consider the effect of both on socio-cultural systems of dwelling and identity. In addition, the media strategies used by design fiction in other disciplines, such as product design, do not exist in architecture. As design fiction is focused on technology, architecture needs to consider the role of technological elements in larger spatialized and compositional systems through social effects.

PAPER #7.02

WHAT DO WE TALK ABOUT WHEN WE RESEARCH THE CITY? ACADEMIC PUBLISHING IN URBAN STUDIES

Débora Domingo-Calabuig[a]
[a] Universitat Politècnica de València, Valencia, Spain

ABSTRACT

When we talk about urban studies, we focus on the physical environment that gives support to social, political and economic relationships, and therefore the approach is usually transdisciplinary and diverse. Research projects are broadly communicated to the scientific community through academic publications, and particularly through journals. Therefore, these periodicals on urban studies have concentrated on specialized scopes and have been included in indexes and databases according to their relevance. The academia has agreed to trust journals for measuring the research impact, but the question is raised about its general visibility in terms of real knowledge transfer.

This paper maps the scientific production about the city through the periodicals of recent years: we census a total of 682 journals related to urban studies on the Web of Science, Scopus, ERIH PLUS and the DOAJ platforms. We aim to know which journals support what kind of works, how different areas of knowledge intersect in them, which countries produce one or another type of research, and what study methods are used in research about the city. In addition to the quantitative results, the objective is to make a critical reading about the impact of what is published. In this regard, a final comparison is also made by putting in parallel the articles included in the most relevant journals and the research projects about the city and its particular problems that have been encouraged by the last Framework Program of the European Union.

The results show a clear fragmentation of the urban studies subject area and a traditional framing of the topics, with little presence of emerging issues. Besides, the research funds percentage is lower than in other knowledge areas. Finally, this study reveals a very limited open access to research that undoubtedly determines its visibility.

KEYWORDS

Urban studies; research journals; architectural research; research impact.

INTRODUCTION: TALKING, RESEARCHING, PUBLISHING ABOUT THE CITY

The ability to select a good topic is something that researchers strive for their entire academic career. Whether it is for the opportunity to belong to a reputable laboratory or to receive a PhD grant, the thematic fields are essentially in reach, according to our knowledge on the subject. In the urban studies, different disciplines intersect that reflects the diversity and complexity of urban problems and solutions. Such as the themes outlined in this conference, the city has many sides: experiential, participative, narrative, history, technical, etc. These perspectives interact in a research proposal and contribute to improving our cities, but: what do we want to research about the city and why? How is this research generated and communicated? To answer these questions, this work follows research on urban studies through academic publications

and maps, although in a biased way, what we talk about when we research the city. Research results are transmitted in several ways in the academic world. Any policy paper from any institution establishes the difference between written output (articles, books, conference proceedings) and non-written production (patents, exhibitions, documentaries) (ACSA, 2017; ACSA, 2019). However, and because of their immediacy in the processes and their impact on the university community, the articles published in scientific journals reach a growing relevance. In terms of research quality evaluation, and regardless of our position in this regard, the journals are classified in indexes with impact factors while other contributions meet less regulated criteria. High-impact journals are the priority spaces when choosing how to communicate a project's results, among other things, because they have an impact on the careers' promotion (Clemens et al. 1995; Rawat and Meena 2014). We shall admit that this study is not without limitations due to the range of the questions asked and their restricted answers, but we aim to offer at least some information that can foster new reflections.

1. THE STUDY SAMPLE: JOURNALS ON URBAN STUDIES

Within the vast panorama of urban studies journals, we select the indexes generally best valued in terms of research results, those published on the Web of Science (WoS) platforms (by Clarivate Analytics) and Scopus (by Elsevier). These scientific information services elaborate specific databases (Science Citation Index Expanded, SCIE; Social Science Citation Index, SSCI; Arts & Humanities Citation Index, A&HCI; Emerging Sources Citation Index, ESCI; Scopus) and journals' lists (Journal Citation Report, JCR; SCImago Journal Rank, SJR), whose quality contributions are commonly accepted thanks to the review process and openly communicated editorial policies. In this specific case, and given the direction that we want to go in with this study, we add to the display the data of the European Reference Index for the Humanities and Social Sciences (ERIH PLUS) and the Directory of Open Access Journals (DOAJ). For each of the information sources, we take as a base of this study the available data according to its mediums: web pages, reports, and databases. Thus, this study includes the articles published in the journals whose categorization corresponds to Urban Studies of the WoS, Scopus, ERIH PLUS and DOAJ platforms: we census a total of 682 journals. We establish a temporary boundary between 2013 and today: these six years exceed the usual 5- and 3-year periods in impact calculations and "h" indices, and include the entire H2020 framework program with which we will try to contrast the results. The sample is not limited to geography (according to the publisher's location or according to the author's affiliation) so as not rule out possible intercontinental collaborations. The working method is of a statistical type, although bibliometric indicators are alternated with qualitative analysis of representative cases. The data interpretation should be understood within the margins of error produced by the sample and its analysis. Also, not all databases provide the same indicators, so certain readings are made only with specific information sources. Consequently, the analyses and interpretations are more from the perspective of the urban and architectural researcher than from experts in library science.

2. WHERE DO WE TALK ABOUT THE CITY?

When locating the publications for this study, we must point out that each of the databases used has a different cataloguing of knowledge

areas. In the case of the Master Journal List of the WoS, the two categories "Urban Studies" and "Regional & Urban Planning" belong to the Social Sciences area. Scopus associates the code 3322 to 'Urban Studies' that is included in the "Social Sciences & Humanities" subject area. The ERIH PLUS has recently implemented the Field of Research (FOR) system from the Australian and New Zealand Standard Research Classification (ANZSRC) but uses a 2-level structure for 2 and 4-digit codes: "1205 - Urban & Regional Planning" is included in "12 - Built Environment & Design". Finally, the DOAJ follows the categorization of the Library of Congress: the contributions are equally distributed among "Cities. Urban geography" (in the "Geography, Anthropology, Recreation" section), and "Urban groups. The city urban sociology" (in the "Social Sciences" section). A first observation is related to the scarce presence of these journals in the global publications' landscape since they do not exceed 0.5% of the total periodicals, except in the case of ERIH PLUS where it barely reached 4.5% despite being an archive of social sciences and humanities publications. Furthermore, Urban Studies journals are published primarily in Britain and the United States, although this data varies significantly according to indexes: WoS and Scopus reflect an Anglo-Saxon domain pattern, while in ERIH PLUS and DOAJ they are strongly positioned in Continental Europe and South America (Fig. 1). The countries that publish the most on urban studies are the United Kingdom with 104 journals and the United States of America with 67, followed by Brazil, Spain and Poland, with 62, 57 and 41 periodicals respectively.

3. WHAT DO WE TALK ABOUT WHEN REFERRING TO THE CITY?

In the same way that we talk about the city under multiple disciplinary approaches, journals are not classified exclusively into categories similar to urban studies but instead, belong simultaneously to other thematic areas. Visualizing these areas overlapping (according to each database classification) allows us to demonstrate a first nature of research on the city (Fig. 2). The diagram for the 107 journals in the WoS sample indicates a prevailing number of

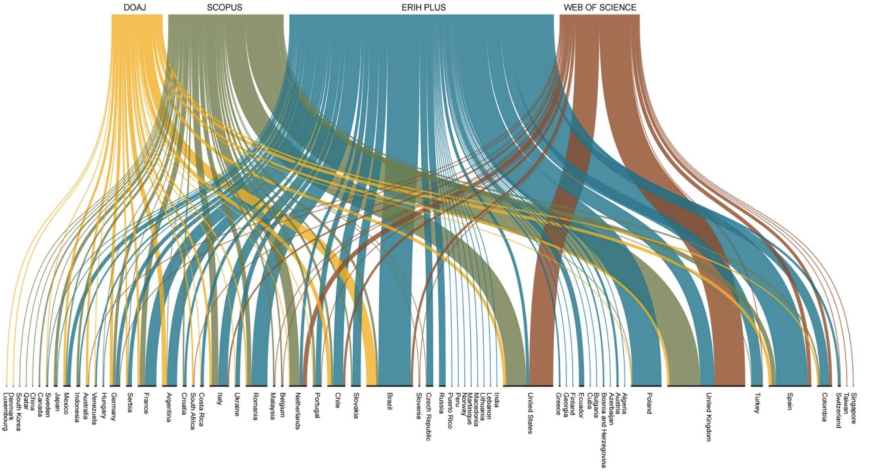

Figure 1. Geographical distribution of the journals related to Urban Studies. Sources: WoS, Scopus, ERIH PLUS, DOAJ. Online data, January 2020.

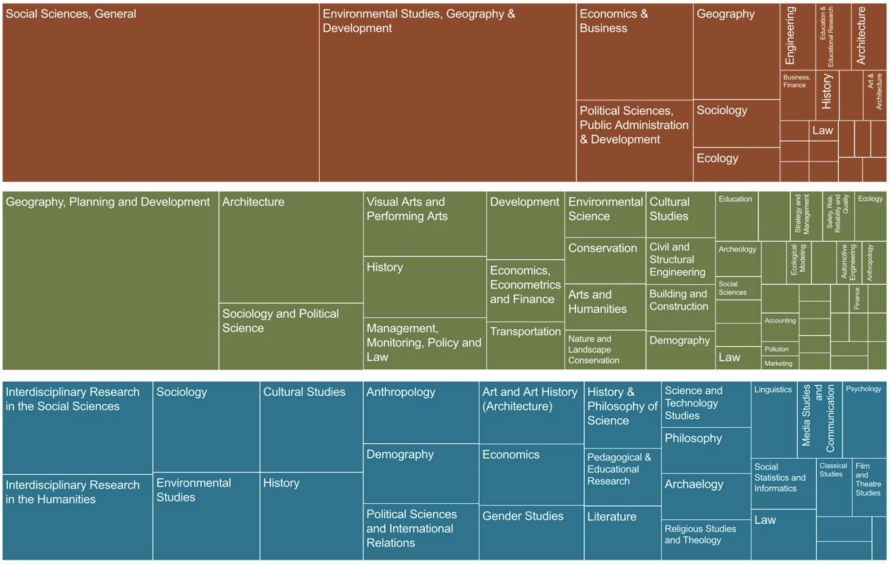

Figure 2. Disciplinary intersects of journals on Urban Studies: simultaneity with other thematic categories in a) WoS; b) Scopus; c) ERIH PLUS. Sources: WoS, Scopus, ERIH PLUS. Online data, January 2020.

publications in the category "Social Sciences, General" and in "Environmental Studies, Geography & Development". Also, it is especially significant that only 3 of the 157 journals are included in the Arts & Humanities Citation Index of the WoS. In the case of the 154 Scopus journals, the largest number of publications has to do with the category "Geography Planning & Development", followed by "Architecture". The map of disciplines that are extracted from the 353 ERIH PLUS journals is especially detailed since they are all devoted to the humanities, as corresponds to the index itself.[1] The journals of the study sample have published a great volume of texts in the last six years, but only the contributions considered as research articles are here under study. In that respect is an upward trend in the number of items in the last six years (from 6500 to 9000 in the case of the WOS) and the dominance of the WoS and Scopus products that offer 6 more times articles per year than ERIH PLUS and DOAJ. We analyse some bibliometric indicators of the most representative journals to get a general idea of the research topics. We are interested in which journals publish more articles and what they focus on (Fig. 3). A keywords analysis is carried out in the highest impact journals, though admitting that the Impact Factor (WoS), or the SJR and the SNIP (SCImago Journal Rank and Source-Normalized Impact Paper, Scopus) are related to the research visibility in the academic community (Garfield 1999; Colledge 2010). The journals that publish the greatest number of articles per year are coincident in WoS and Scopus, but if we look for the most productive journals in ERIH PLUS, the publications are completely different.[2] The DOAJ does not offer this data.

[1] The DOAJ does not allow to extract this type of information and therefore it is not here considered.
[2] However, all journals included in ERIH PLUS are also in Scopus. The differences are due to the cataloguing or to the greater number of articles published in WoS and Scopus.

Figure 3. Journals with the greatest number of articles published and their most frequent keywords from 2013 to 2019. Sources: WoS, Scopus, ERIH PLUS. Online data, January 2020.

A sub-sample of the WoS and Scopus is carried out so we can attempt a visualization of the articles published in high-impact journals.[3] By combining the "Urban Studies" and the "Regional and Urban Planning" categories in the WoS, we get 109 indexed journals; in Scopus 154 journals are included in the category "Urban Studies" of SJR. If we cross both data, the resulting amount is 216 journals, 45 of which are simultaneously in both indices, and 26 of them are in the first quartile of one or both of the two rankings (JCR and SJR).

The keywords of the 10,888 published articles between 2013 and 2019 in these 26 journals of greater impact show research mainly based on planning –its development, its policies, its economic factors–, an important presence of residential issues, and a relevant number of studies located in China, the United States and the United Kingdom (Fig. 4).

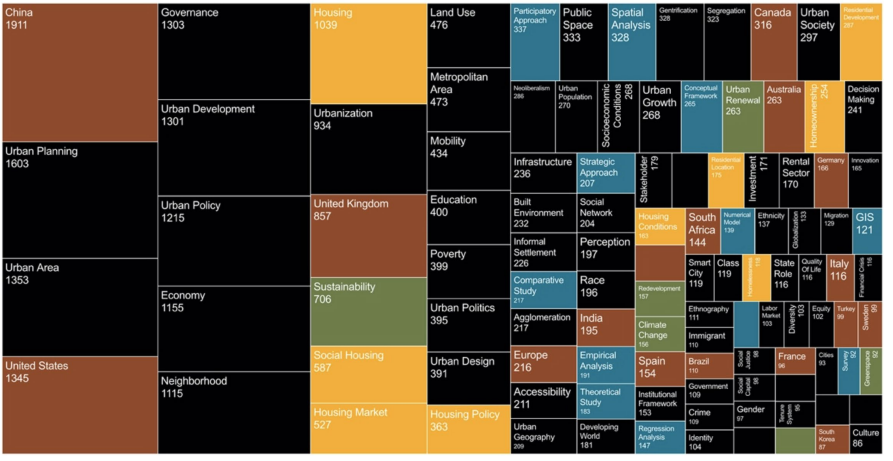

Figure 4. Most frequent keywords in articles published in high-impact journals related to Urban Studies from 2013 to 2019. Sources: WoS, Scopus. Online data, January 2020.

[3] ERIH PLUS and DOAJ do not order their journals according to quantitive value. Equally, WoS journals included exclusively in the Arts & Humanities Citation Index cannot be considered either in this sub-sample as they have not an impact factor.

4. WHO RESEARCHES THE CITY?

From the previous samples, we extract two additional data related to the authorship or the promotion of the research projects on urban studies. It is relevant to know who is researching the previously indicated subjects and who is financing them (Fig. 5). It is surprising to discover that only 30.4% of the contributions acknowledge a funding source, especially if we relate these articles to research projects awarded in open calls. The funded projects are selected based on, among other things, their expected impact in solving real problems. This fact would show that approximately 70% of research in urban studies is dedicated to topics "not driven" by administrative interests. However, this same data of not-funded research decreases to values lower than 30% in areas of knowledge such as Chemical Engineering. When the articles of our sample were analysed, some of the keywords –those in blue in Figure 6– referred to research methodologies. We list here these methods by identifying them with their source titles (Fig. 6):

5. HOW DO WE RESEARCH THE CITY?

As an addition to the parameters observed so far, this work explores some of the articles in these journals to analyse how research is done and how it is shown. The differences between some journals are not significant: these are works based on empirical analyses that attempt to quantify the results to build general frameworks for debate. The manuscripts are fundamentally written with little graphic material. Last but not least, we also make visible the vast quantity of research published through "paying walls". The figures for open access publications in Urban Studies are neither better nor worse than the rest of the disciplines, but they do not seem to account, for example, for the Open Access mandate in H2020 (European Commission 2017), or similar policies that exist in many European countries. In our sample, the open access articles only represent 7.67%, and if we extend the analysis to all the journals included in the WoS, the result rises to 20.37%. We can now understand why the DOAJ only included 677 articles on urban studies in 2019 compared to the 9,065 ones indexed by the WoS.

6. WHAT IMPACT DOES RESEARCH ON THE CITY GENERATE?

Research impact is a thoughtful and complex topic. The open calls for project proposals generally ask researchers to specifically state their expected results and what their impact will be. We understand the academic impact as the proof of new knowledge within the scientific community; we mean by "social impact" or "knowledge transfer to society" what has been improved in social problems thanks to an investigation. In the first case, the academic impact is measured through citations. This parameter is not always realistic since only the citations in indexed journals are counted. Alternatively, it can be more inclusive when any mention of media work is computed, as it happens with Google Scholar. The scientific impact of our sample's articles is obviously among the highest level since the journals are located in the first quartile of the JCR (WoS) and SJR (Scopus) lists. The data show how some articles have had up to 289 citations in the last 180 days (and 1793 citations since 2013), and this highlights the thematic link between one contribution and another, that is, the construction of knowledge in a consistent research path. It is not easy to track the impact of research, because the transfer of knowledge can be done in very diverse ways. However, we can outline a possible approach by glancing at the list of urban studies projects granted by the European Union (EU) framework programs (FP) in recent years. The FP has substantially determined the research in terms of financing since its inception. In FP8, known as Horizon 2020 (H2020), the Societal Challenges pillar supported research that "target society and citizens" and included areas such as "Demographic Change", "Smart Green and Integrated Transport", "Climate action and environment", "Inclusive, innovative & reflective societies" and "Secured Societies". Almost all of these issues come from similar denominations since FP4 (1994), although it should be noted that some are newly created: the term "security" appears for the first time in FP7 (2006), and the concern for social integration is incorporated only in H2020 (2013) (Reillon 2017). The preliminary structure of Horizon Europe includes in the pillar of "Global Challenges and European Industrial Competitiveness" various clusters with the aforementioned areas. This structural evolution shows an intention to obtain breakthrough solutions coming from multi-disciplinary collaborations. Regardless, the funded projects of these open calls are endowed with financial resources and must demonstrate the impact of their results through academic publications and dissemination actions.

Figure 7. Funded research projects where urban studies are involved in the sub-programs H2020. Sources: CORDIS and Open-H2020 observatory, January 2020.

For almost three decades now, the CORDIS database offers information on projects and their results, classifying these by areas and sub-areas: 12 projects are included in the programs. The results always mention two chapters: "deliverables" (reports, pilots, websites) and publications (books, conference proceedings, but mostly peer-reviewed articles). The subjects of smart city, sustainable energy, urban regeneration and social cohesion emerge through these analyses (Fig. 7). One can find in their web sites the impact that each of the projects has had on social contexts: specific actions in the consortium cities, webinars and press releases.

CONCLUSION: WHO DO WE TALK TO WHEN WE RESEARCH THE CITY?

If we were to come up with a headline, we could say that we speak little when we research the city: other knowledge areas are more productive in writing. We do it in diversified forums that do not offer a simple and a global overview because urban studies have a multidisciplinary nature and a contribution might be included in similar categories and under different names. Mostly, our research is not supported with funding –other subject areas are much more financed– and therefore, the issues we address on our own are unlikely to be coincident with our institutions' interests. Besides, we talk 'in a closed circuit' and what we say remains in a very small area, so we may not see much beyond this. Finally, we talk about topics that do not seem to correspond fully with the emerging issues of interest, at least if a comparison is made between the most cited articles and the funded projects entrusted for applied results. This conclusion would support existing studies that warn of the black-boxing of academic communication and its evaluation, thus paraphrasing the black-boxing that Latour coined when referring to the development of scientific research (Bruni and Magaudda 2017). The high-impact journals on urban studies (those that are more relevant for the research evaluation) are less visible to the scientific community. Therefore, the topics discussed in them do not need to be directly linked to real needs. Finally, this study shows that it is not an easy task to monitor the transfer of knowledge. Who do we talk to when we investigate the city? We speak for few, but it has repercussions on many and it is difficult to trace the path because the track is lost. Recipients of the research

results are the general public (citizens), the service providers (transportation, energy), the management decision-makers (community organizations, and private businesses), and the policy decision-makers, but the contact details with this target audience are lost beyond the results reports of a project. The questions about the effectiveness of the knowledge transfer asked in other areas (Lavis et al. 2003) could help to reflect on our urban studies.

PAPER #7.03

A MODEL FOR COMMUNITY AND CRITICALITY: THE UNIVERSITY URBAN DESIGN AND RESEARCH CENTER

Courtney Crosson[a]
[a]University of Arizona, Tucson, Arizona, USA

ABSTRACT

University urban design and research centers link academic pedagogy and research to real world applications. As the rate of urbanization accelerates and universities' missions become increasingly grounded in visible impact and financial self-sufficiency, these centers continue to offer an important and appealing model. These centers have doubled over the last two decades, yet a systematic investigation of their growth, successes, and failures does not exist. From a survey of over fifty centers throughout the United States, a typology is established based on the dominant activity of each center: Advocate, Consultant, Educator, and Scholar. Case studies from each mode are examined at greater depth. Overall, this paper finds continued growth in the number of these centers and a recent broadening of involvement by a diversity of academic and professional disciplines. Given this expansion, this paper is a tool for emerging centers to frame their missions within an established typology and gain best practices. Across all modes, universal challenges include: sustained funding, administrative support, and clarifying student and community roles. These centers are important models for universities to demonstrate visible impact and establish diversified revenue sources.

KEYWORDS

Community design; urban research center; urban lab; service-learning.

INTRODUCTION: THE NEED FOR A FRAMEWORK

This paper examined centers, labs, initiatives, projects, or institutes that formalize a link between universities and the urban planning and design of the communities in which the university sits. For ease, this paper titles these formalized links *university urban design and research centers* or *centers*, but recognizes the great variety under this umbrella. Certainly, each center in the study will continue to evolve and, in the long term, may alter the activities and purpose captured in this paper's assessments. In an attempt to make a broad and thorough study of centers, this paper includes the margins in order to identify emerging approaches and guarantee a complete sampling.

Recent Assessments of Centers

The literature on university urban design and research centers offers discrete analyses of the successes and failures of centers within research and education goals. However, this literature falls short on establishing a cohesive framework to characterize and evaluate centers across multi-dimensional objectives. This paper addresses this existing gap through a systematic study of over fifty centers to provide a relational framework comprised of four modes.

Centers that produce academic research within a community-focused mission face several consistent challenges. The largest issue highlighted by the literature is sustaining funding once it is acquired (Baum, 2000; Peason, 2002; Stahler and Tash, 1994). If the university is not able to offer stability to the center by supporting its annual operating

budget, the center must rely on grants, awards, and professional consulting service fees. Despite these challenges, Gerald Stahler and William Tash (1994) identify research centers as one of the most successful methods by which universities secure outside funding.

University-community partnerships run through educational courses are often challenged to meet initial, community expectations due to limitations in student abilities and the semester timeframe (Baum, 2000). Matching community expectations of professional quality work with student abilities and motivation is underlined as one of the greatest challenges of community-engaged pedagogy (Neuman, 2016; Dorgan, 2008). Real world projects often have timelines that are out of step with academic schedules and faculty have little ability to incentivize students to complete work outside of the structure of grading (Forsyth, 2006). To address these gaps, Howell Baum (2000) emphasizes approaching projects with realism: setting purposes that are clear, specific, and realistic; on matching purposes to resources; making partners accountable to one another; and in continual organization.

Recent Surveys of Centers

In 2002, the National Endowment for the Arts (NEA) published a directory of university-community design partnerships (Pearson, 2002). Rather than a framework, this directory catalogues centers that are a shared university-community enterprise and currently take on projects that use design as a tool to take action. This definition is narrower than the work undertaken by this paper's study. In an assessment of these partnerships, the NEA reports that while the work of these programs is impactful at a local scale, the learning outcomes often fall short of a national impact on community development objectives (Pearson, 2002).

In a 2006 article, Ann Forsyth looked at a broader definition of centers than the NEA directory, more aligned with the scope of this paper. She outlined and critiqued seven approaches to university-community partnerships: research centers, university firms, community advocacy center, extension, studio, clearinghouse, and umbrella organization. This outline provides an overview of types of activities undertaken by centers. Forsyth's article speaks in general terms from observations and experience. This paper provides a systematic examination of existing centers. It builds on the directory by NEA and the characterization of centers by Forsyth to analyze the growth of centers, modes of operation, and specific opportunities and challenges. It ultimately provides a relational framework of the broad diversity of centers that exist today.

1. METHOD: EVALUATING UNIVERSITY URBAN DESIGN AND RESEARCH CENTERS

The methodology of this study involved three stages: survey, framework formulation with the creation of a timeline, and framework testing through case study (see Figure 1). First, a survey of the existing urban design and research centers in the United States was conducted. The list of top twenty-five public universities (US News and World Report, 2016), top twenty-five private universities (US News and World Report, 2016), top 25 graduate urban planning programs (Planetizen, 2016), and top twenty-five schools of architecture (Design Intelligence, 2016) were investigated for the existence of a center. Over fifty centers with an urban, multidisciplinary focus were identified within many of these universities. Data was gathered by reading centers' websites and blogs, related news articles, and social media presence. Additional information was gathered by contacting the directors, administrators, or faculty members involved in each of the organizations through email and phone. During these conversations, the interviewees referenced other centers for inclusion in the survey. Reviewed literatures were also drawn upon for the survey.

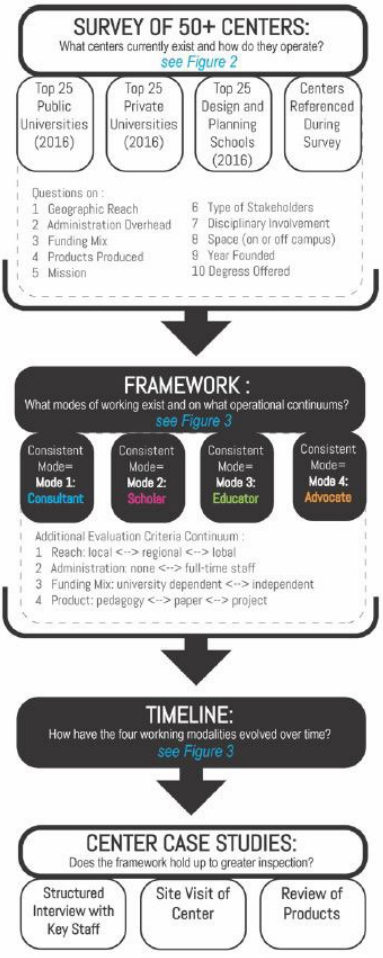

Figure 1. Research Methodology (Author 2020).

1.1. Survey of Centers

A comprehensive spreadsheet was created to document the information generated from the survey process. The spreadsheet recorded detailed information on each center including geographic reach, administrative overhead, funding mix, products produced, mission, type of stakeholders, disciplinary involvement, designated space (on or off campus), year founded, and degrees and classes offered. From this master list, over fifty centers were identified, relationally mapped, and organized chronologically to understand trends and relationships. Figure 2 diagrams the translation from consolidated spreadsheet to relational representation. The centers were charted on two axes: type of product (paper to physical) and type of activity (thinking to doing). Additionally, each center was encircled with the disciplines that were involved from their host university. Although planning, architecture, art, and landscape architecture dominated in involvement, some of the most dynamic products were produced in centers where there was involvement from other fields including sociology, geography, engineering, and political science. In this diagram, centers that have off-site locations are tagged and stakeholder involvement is indicated through color. Most centers broadly engaged with students, community members, and the professional community.

1.2. Categorization: Establishing the Framework and Timeline

The second stage was to interpret the gathered information in the spreadsheet to inform a set of deeper case studies. From an analysis of the activities and voiced purpose of the centers, a framework was developed based on four dominant modalities: Consultant, Scholar, Educator, or Advocate. These are represented by distinct colors in Figure 1 and 3. Although most centers engaged in all four modes, each center was tagged with a primary activity. Two main questions drove the categorization process: (1) who is doing the majority of the work production (e.g. students, faculty, administrators, or community collaborations) and (2) who is paying for the majority of the work (e.g. tuition revenue, research grants, contracts, or mission-driven foundation grants)? If the majority of a center's products were produced

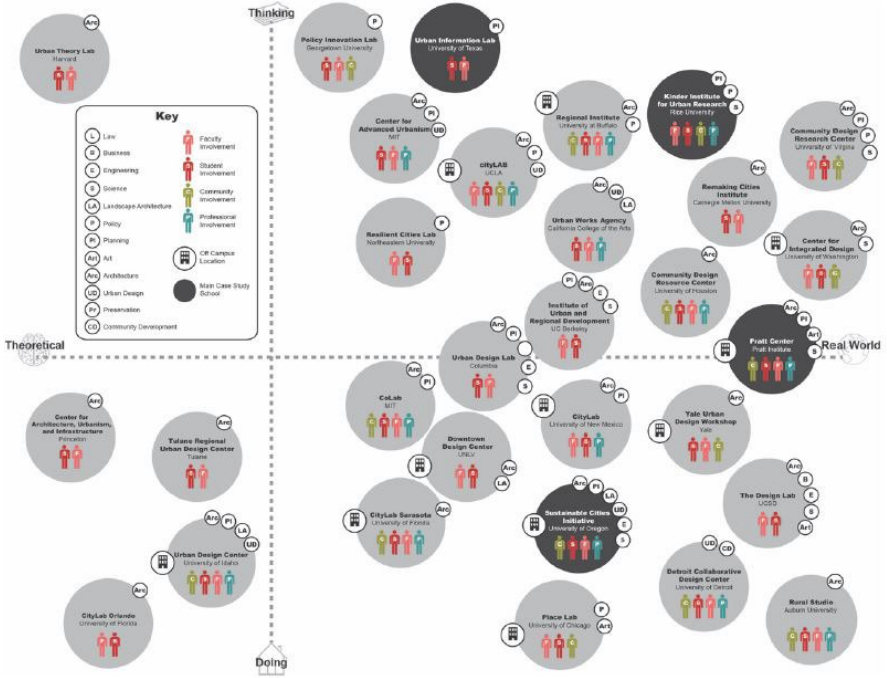

Figure 2. Initial Mapping of University Urban Design and Research Centers (Author 2018, with contribution from research assistants Andrew Marriot and Queston Kwolek).

by students and funded through tuition dollars, it was classified as an Educator. If the majority of work was produced by faculty and funded by grants, it was classified as a Scholar. If the majority of work was produced by a variety of positions with substantive administrative support and funded through contracts, it was a Consultant. If the majority of the work was produced in collaboration with community groups with support from Foundations and mission-driven organizations, it was an Advocate. Additionally, some centers have emphasized different modes over time, but the categorization focused on the current status of the center in the last year. Two graphic tools were created to organize the centers and understand the evolution and current operation of these modalities. A timeline, Figure 3, tracks the creation of these centers against historic trends. Various decades see greater growth or a higher disposition toward certain modalities. A consolidated line diagram, Figure 3, links each center and modality with type of funding, administrative capacity, extent of reach, and product produced. This graphic decodes dominant clustered operational behaviors of different modes.

1.3. Testing the Framework through Case Study

In the third stage, one case study was completed for each of the four modalities to test the framework and understand the great variety within each mode. Additional case

studies were completed to cross examine this main case study. In depth interviews with a set of preset questions with the current director of the center were conducted to gain this deeper picture of operation. Site visits were also conducted by the author to see firsthand the physical location and functioning of the center. A comprehensive review of the center's products, available through the center's website or physically acquired during the site visit, was done. Findings are discussed in the following sections.

2. RESULTS: A FRAMEWORK FOR THE UNIVERSITY URBAN DESIGN AND RESEARCH CENTER

Once this data was gathered from all three methodological stages, results were analyzed. This section shares these results across the strengths and challenges of the four modes. The ultimate aim is to provide guidance for universities seeking to start similar centers or current centers to contextualize their efforts.

2.1. The Consultant Mode

These centers are typically project based and are not focused on theoretical research. Funding usually comes from community and industry partners and grants, but not the university. These centers typically require at least one designated administrator to function (usually to pursue grants and manage multiple incoming monetary streams). They use mainly the professional skills of faculty to assist partners in design or social change work. Overall, these centers were the most financially successful. They had the largest annual budgets and consistently excelled at securing large, multi-year funding sources. The work produced by the Consultant mode often had quick and direct impact as the projects were framed to answer a specific need and were output oriented. However, the Consultant mode often struggled to fit easily within the bounds of the university setting. Challenges included projects driven by client needs rather than intellectual discovery, misalignment between the projects that clients were willing to fund and the specific interests of research faculty, and lack of student learning due to the narrow objectives and strict timelines of client funded projects. Another common issue voiced by the Consultant mode was a perception of the center as taking work from professional partners within their communities. This perception went against the community engagement mission of these centers. Consult mode examples include: Kinder Institute at Rice University and the Yale Urban Design Workshop (mainly supported through contracts for real projects), Columbia University's Urban Lab (garnering funding from internationally commissioned studies and projects), and Colorado States' Institute for the Built Environment (largely executing contract research work). Each of these cases has at least one administrator who oversees development and contract execution. These centers are not formally associated with courses or curriculum within the universities.

2.2. The Scholar Mode

These centers are focused on theoretical and applied research. Funding usually comes from the university or grants. The majority of collaboration tends to happen within the university and its bodies, rather than with the government or community partners. Little to no administration (outside of the typical facilities and administration provided by the university) is needed in this mode. The work products from these centers included journal articles, books, newsletters, and blogs. Oftentimes, impact of the work extends out to other universities or professionals who bring theories to reality or expand on the knowledge-base related to the work. As the output of this mode is mainly publications, it syncs well with a typical university promotion structure that prioritizes academic publications. Additionally, this mode was often a positive mechanism to encourage multi-discipline

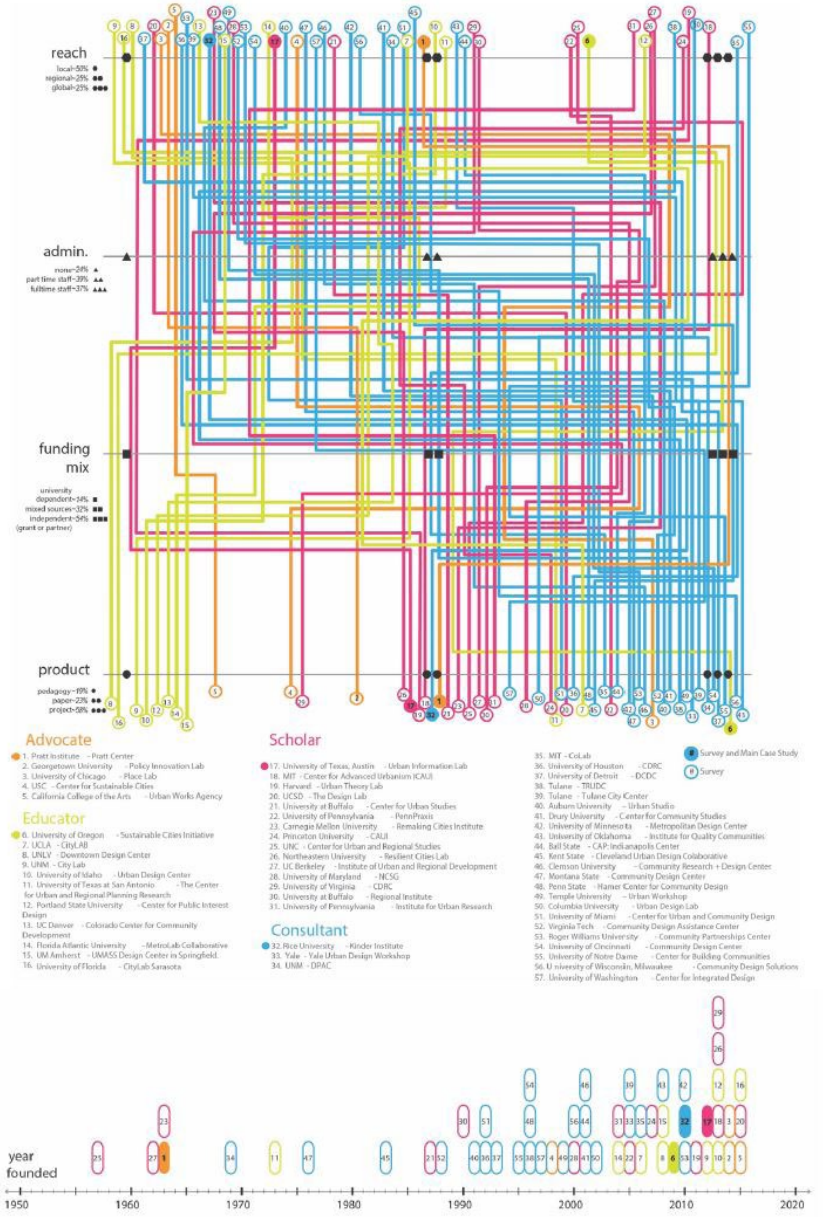

Figure 3. Timeline and Modalities of University Urban Design and Research Centers. (Author 2018, with contribution from research assistants Andrew Marriot and Queston Kwolek).

and multi-sector collaboration and provide graduate and advanced undergraduate research opportunities. One downside was that work from the Scholar mode was often less connected to the community. Academic publication did not always communicated in a way that was accessible and useful to community members. This mode largely relied on faculty to administer the center. Due to limited time, centers led by a faculty administrator were often steered toward the faculty member's own research agenda. Thus, in the Scholar mode, the center's work seemed less agile to new needs or demands of community partners. Scholar mode examples include: University of Texas-Austin's Urban Information Lab, Harvard's Urban Theory Lab, University of Pennsylvania's Institute for Urban Research, Massachusetts Institute of Technology's Center for Advanced Urbanism. All of these centers mainly produce academic publications and are supported largely by grants and the universities in which they sit.

2.3. The Educator Mode

These centers are focused predominantly on teaching the next generation of planning and design professionals. Funding is almost all university (tuition) based. Some centers in this mode hired additional administrators to handle development and dissemination of work (particularly if construction was involved). Service-learning and design-build pedagogies are strategies commonly used by these centers. Positively, the Educator mode supports the core mission of the university to educate. This mode provides real-world project experience to students, particularly aligned with professional schools of planning and architecture that seek to produce practice-ready graduates. This mode also appeared more able to respond to local community needs because the center is funded through a stable stream of tuition revenue rather than beholden to the fluctuating demands and interests of clients or grants. Centers in this mode took on more pro-bono and short-term projects. Challenges faced by this mode included inconsistent quality of products due to the limitations of the academic calendar and student effort and skill and variability in community connection because of a constant turnover of students. Educator mode examples include: University of Florida's CityLab (offering degrees and classes directly through the Lab), Texas A&M's Institute for Sustainable Communities, and Auburn University's Rural Studio (delivering the majority of its work through coursework). These centers are all focused on the dual mission of connecting with their communities and supporting student learning.

2.4. The Advocate Mode

These centers focus largely on policy advocacy and public education for the betterment of communities. Funding comes from those looking to promote change – be it the university, community partners, or national organizations. This typology typically has at least one administrator (such as a director) to clearly guide the mission and fundraise. The impact of the Advocate mode ranges from simply distributing knowledge to changing laws for the public good. Few of the surveyed centers were classified under the Advocate mode, though many hybridized Advocate activities with their dominant mode. This mode strongly focused on community needs and supported long-term community relationships. With the right mission, these centers received sustained, multi-year funding by mission-aligned foundations and organizations. One challenge faced by this mode was a conflict between the political nature of advocacy and the apolitical mission of institutions of higher learning. Additionally, some faculty found it difficult to situate their scholarly publication incentives within the work of these mission-driven centers. Advocate mode examples include: Pratt's Center for Community Development, Georgetown's Policy Innovation Lab (focused on informing and changing

policy) and University of Chicago's Place Lab (emphasizing advocacy for communities surrounding the university).

3. DISCUSSION: VARIATIONS WITHIN AND BETWEEN THE FOUR MODES

During the creation of this framework, three inter and intra mode variations were observed: (1) operations,
(2) hybridization between modes, and (3) transitions of modes over time. The next section discusses these dynamics between the four modes.

3.1. Four Modes: Operations

During categorization, centers were also mapped against four operational continuums: geographical reach, administrative support, funding mix, and type of products produced (Figure 3). Generally, the Consultant mode tended to have a regional to global reach, require greater administration support, secured higher volumes of funding largely from industry, and produced professional products. The Scholar mode tended to have a broad reach, required less administrative support, secured moderate levels of funds largely from grants, and produced academic publications. The Educator mode tended to have a local focus, required little administration, derived funding from existing tuition dollars, and produced semi-professional products. The Advocate mode tended to be locally focus, have greater administrative support, successfully secured larger amounts of funding from mission-driven foundations, and produced products that directly address community identified needs. At the time of the survey, half of the over fifty sampled centers were locally oriented, with only a fourth (25%) with a global mission. The majority of centers (54%) were financially self-sustaining through grants and contracts, with only 14% relying solely on university funding. Projects were the dominant output of 58% of centers, with a balanced divide between pedagogy (19%) and papers (23%) as alternative products. A variety of administrative models either within departments or spanning multiple disciplines exist. More than three quarters of centers (76%) relied on additional part or fulltime employees to operate. Research work overwhelmingly used an applied rather than theoretical methodology (Figure 3).

3.2. Four Modes: Combinations

Within a dominant mode category, there are several hybrids or combinations. Take for example, a center that does the majority of its work in the Consultant mode, but also acts as an Educator and Advocate. Such a center receives the majority of its funding from industry partnerships and paid reports, but also acts as an Educator when it hires undergraduate, graduate, and post-doctorates to carry out the work. Additionally, this same center can play the role of an Advocate for the particular mission of the agency supplying funding. In other cases, centers are Educator-Scholars (primarily tuition revenue focused, run through coursework and occasionally publishing papers from course products) or Scholar-Consultant- Advocates (principally grant focused with additional streams of revenue from contracts, powered by faculty time, demonstrating impact through scholarly publications while advocating for community wellness through progressive urban design). Although each center is classified by its dominant funding source and work product, most centers engage with a community through a myriad of processes.

3.3. Four Modes: Transitions

Additionally, many centers have transitioned from one model to another over time. Transitions are most often spurred by a change in the interests of the center's leadership or funding availability. For example, the Kinder Institute at Rice University initially grew out of a course that produced an annual

comprehensive area survey documenting the changes in Houston over time. It was funded by tuition dollars and powered by student work (fitting the Educator mode). As the survey grew, the center garnered grants and several post-doctorates were hired and enlarged the center's academic publication (fitting the Scholar mode). Most recently, the Kinder Institute has switched from a faculty director to an executive director pulled from industry and government experience. The main source of revenue is now a healthy endowment and contracts with industry partners. A marked decrease in faculty involvement has been replaced by hired research associates to complete the terms of contracts (fitting the Consultant mode) (Klineberg, 2018). This one example is indicative of the journey of many centers across the country over time – endeavoring to stay nimble within changing funding availability and institutional expectations.

CONCLUSIONS: A FUTURE OF ENGAGED WORK, SCHOLARSHIP, EDUCATION, ADVOCACY

University urban design and research centers link academic pedagogy and research to real-world applications. These centers provide an infrastructure for faculty, students, and research staff to complete research, coursework, and projects that engage with urban planning and design practice. Four modalities (Educator, Scholar, Consultant, and Activist) structure a framework to understand the diverse work of these centers. Variations within and between these four modes include operational factors (administrative support, funding sources, geographical reach, and material outputs), hybrids, and transitions. This paper addresses a current gap in a systematic study and relational understanding of these centers.

Overall, this paper is a tool for universities interested in starting a center to develop their own missions and for existing centers to contextualize their efforts within a systematically established framework. The strengths and challenges and analyses of the four modes can be weighed by universities in this position. The Consultant can encounter complaints by the professional community of unfair competition, yet also has demonstrated the greatest capacity to expand university revenue. The Scholar can endure yearly budget uncertainties between grant funding cycles, yet most naturally fits within the skillsets and incentive structure of faculty in a tenure system. The Educator may enjoy a stable university budget, but struggle to meet the expectations of the community partners within the fixed schedule of coursework. Further, the Educator seems to be the easiest center to initiate, as it functions within existing coursework structures and there is little new overhead. Finally, the Advocate may encounter misunderstandings of their role of advocating for a community while staying apolitical, especially if the center sits within a state university. This mode seems to be the best model for targeting specific issues or desired areas of change within a community. All four modalities can demonstrate visible impact and bring diverse sources of revenue for universities. Overall, centers continue to expand in number and mission across the country and involve a widening set of multi-discipline academic and professional interests.

PAPER #7.04

PEER-REVIEW OR POPULARITY-CONTEST: THE EROSION + IMPLOSION OF INTERNAL ASSESSMENT IN HIGHER EDUCATION

Brian Robert Sinclair[a]
[a] School of Architecture, Planning + Landscape, University of Calgary + sinclairstudio inc, Canada

ABSTRACT

Architectural education historically has an awkward existence in the academy, in part due to strong links to the profession and in part due to subjective dimensions. Universities struggle to understand environmental design fields, reluctantly accepting creative endeavors as valid undertakings yet questioning an absence of empirical rigor, methodological discipline and measurable outcomes. Within this complicated milieu falls the task of faculty performance review. Universities develop guidelines for promotion, tenure and merit that attempt to cover the broad spectrum of fields dwelling in the halls of higher learning. In many instances general solutions are simply inadequate. Within colleges of architecture, unique evaluation policies are established that seek some resolution between discipline-specific circumstances and generally-applicable expectations. It is a rough fit at best. The subjective nature of environmental design has implications on student work, academic research and faculty assessment, to name but a few impacted realms. While external review, such as journal article consideration or conference paper evaluation, is commonly blind, the assessment of faculty on university campuses is never such. Rather than being objective and blind, these evaluations are commonly tainted with politics. Inappropriate aspects, such as a faculty member's popularity, philosophical posturing or pedagogical positioning have undue negative influence on delivery of fairness and execution of justice in determining meritorious performance. The present meta-enquiry argues that within architecture schools such loose and slippery qualities are heightened and amplified, based in large measure on subjective grounds used to evaluate many activities in the ethos, including design. The research examines literature exposing flaws in assessment within the academy and builds arguments for further and more focused study. Design faculty often claim uniqueness and difference as grounds to opt out, in part, from larger university guidelines. However, departing from universally accepted norms opens doors for abuse, arbitrary judgements and inequity. The paper provides a provocation, and opens the door to an emergent field of research, that is proving both urgent and significant. The author paints an initial picture of a complex landscape that is often ignored in higher education, and as such encourages broader and deeper investigation of topics that strike sensitive yet vital cultural, legal, social and cognitive chords.

INTRODUCTION

> "Education is about healing and wholeness. It is about empowerment, liberation, transcendence, about renewing the vitality of life. It is about finding and claiming ourselves and our place in the world." Palmer[1] (1999)

[1] Palmer, Parker J. "The Grace of Great Things: Reclaiming the Sacred in Knowing, Teaching and Learning". In The Heart of Learning: Spirituality in Education. Editor: Steven Glazer. Tarcher/Putnam: New York New York. 1999. Pp 18-19.

Universities tend to take great pride in the rigor and discipline required to discover knowledge, search for understanding and solve problems. Without doubt our present world is overflowing with crises and catastrophes that warrant our attention, ingenuity, wisdom and resolve. Within such a demanding milieu many academics rise to the challenge, pushing hard to consider the complexity of dilemma and to chart viable paths forward. Higher education is a unique environment where freedom of thought is supported and unconventional thinking is encouraged. In this ethos, competition runs high and over-achievement is commonplace. Faculty vie for position and fight for the finite rewards, monetary and otherwise, that accompany the conferral of the title 'meritorious'. However, the game is zero-sum, filled with winners and losers and perhaps a few scattered serendipitously in-between. Modern societies increasingly lose sight of the notions of right and wrong, truth and lie, good and bad, and fair and unjust. In times when governments have abandoned moral compasses, and elected officials drool in their pursuit of money and power, it is understandable how ripples reach far and wide. The university, of course, is in no way immune to the plague of politics as it seeks to acknowledge achievement, reward accomplishment and honor those deemed worthy. In fact, the present paper argues that in many ways the academy falls victim to moral decay and 'might makes right' mentality propagated by powerful politicians, corporate leaders and others who routinely abuse position and power – all too often placing self-interest, self-promotion and self-gratification well above qualities of compassion, charity, grace and the support of the community.

1. BACKGROUND

> "Complicating matters are colleagues who in social situations appear collegial, congenial, and supportive to the victim but in private become just the opposite.
> The victims are excluded, disenfranchised, silenced, overlooked, or ignored." Twale + De Luca[2] (2008)

One of the potent tools used within the academy to assess performance and measure impact is peer review. In its purest sense, that is when truly blind in structure and execution, peer review is a powerful vehicle to determine the value and significance of work – whether that be a scholarly paper, a grant application, a request for advancement, etc. In such a scenario the identity of the person or persons whose work or performance is being adjudicated is hidden, rendering said assessment more objective, more fair and in principle without political or personal bias. In some cases where there are numerous stages of assessment, the review can be double blind, or more so, in an effort to proffer even more objective outcomes. In some cases, at some institutions, there are selected processes that do deploy blind review. However, this approach for many internal evaluations, such as promotion of rank or merit assessment, is often anything but blind. In a growing number of cases throughout higher education the evaluative systems in place are corrupted by internal politics, swayed by individual personalities, and skewed by power dynamics that unduly tip the scales of justice. In recent years many researchers have cast light onto dark subjects such as incivility, bullying, mob mentality and incessant individualism within the halls of the academy. Such studies point to a growing climate of toxicity in many units on campuses across the USA and Canada.Fueled by heightened competition, stagnant salaries and a culture of greed,

[2] Twale, Darla J and De Luca, Barbara M. Faculty Incivility: The Rise of the Academic Bully Culture and What to Do About It. Jossey-Bass: San Francisco. 2008. Page 24

it is increasingly common to see brutal political games play out in the colleges and departments of our institutions, and of course, to have them manifest in systems of assessment. The research, concerned with an escalating climate of injustice and incivility, critically reviewed recent literature outlining dysfunction in the academy (see, for example: Twale & De Luca[3], 2008; Coates & Morrison[4], 2011; Bennett[5], 2003; Ginsberg[6], 2011; Hollis[7], 2012). The author, with intense experience in senior administration on both sides of the 49th parallel, has witnessed this escalation in attacks, rise in bias and exercises in prejudice within universities. Of course no one wants to admit that higher education could fall into these traps of incivility and injustice – especially given the lofty status many academics ascribe to themselves by virtue of degree and pedigree. However, as in the society looming beyond the ivory towers, the academy's behavior reflects a broader decline and deterioration that must be admitted, owned and hopefully rectified.

2. PEER REVIEW - FAIR OR FRAUD

> "Professors, taken as a group, are far from perfect. They can be petty, foolish, venal, lazy and quarrelsome. Nevertheless, at its best, the university is a remarkable institution. It is a place where ideas are taken seriously; where notions that are taken as givens elsewhere are problematized; where what has seemed to be reality can be bent and reshaped by the power of the mind." Ginsberg[8] (2011)

The concept of peer review is robust and fair when executed with professionalism, mindfulness and care. Key aspects of fairness include impartial review, to minimize politics and favoritism, and deployment of accepted standards, to ensure reasonable enforcement and similar comparison. When peer review is handled in this manner academics, administrators and the public enjoy confidence in the system. Academics understand the nature of assessment, knowing what is deemed meritorious and feeling comfortable that adjudication is being delivered in a balanced and transparent fashion. Even when the game is zero sum, at least there is comfort in knowing the mechanisms for evaluation are rational, consistent and even-handed. In many cases at many institutions the peer-review systems in place operate with fair play front of mind.

In many cases, however, and especially in the current climate of turbulence and distrust, the peer-review process slides south, rendering decisions in ways that delegitimize the system and divide up cohorts into opaque pools of winners and losers. Rather than ensuring blind review, whereby the assessors hold an arm's length to those under assessment, many contemporary approaches are exposed to the dark sides of the academy where popularity is preferenced over performance, where favoritism trumps fairness, and where who you know can matter more than what you achieve. In such scenarios certain groups of faculty stand exposed to far greater risk – for example tenure-track members who are in vulnerable positions and who are subject to serious power differentials. Rather than standing securely on objective review of the merits of their work, as measured by impact factors or awards or funding, they can face subjective judgements based on perceived collegiality, arbitrary assessments of research value, or selective screening of

teaching evaluation commentary. In these cases the direction of the assessment can be predetermined based on goals of sending a message, curtailing freedom, suppressing ascension, or simply engaging in bullying and incivility.

3. ESCALATING DYSFUNCTION

> "We see that there are proclivities toward individualism across the higher education world. The disposition to behave in self-absorbed and self-protecting ways and to put narrow self-interest ahead of the welfare of others or a broader common good is widespread. Individual and institutional identity, worth and fulfilment are understood in terms of power to shape and control others, and to resist their power." - Bennett[9] (2003)

Higher education is a remarkable, potent and positive vehicle within our societies. Critical missions that embrace the power of teaching, the shaping of minds, the building of character, the discovery of knowledge, and service to community, to name but a few attributes of the academy, serve as vital forces to keep society in check and our progress on track. This is not to imply that the academy is ideal, but rather that its many roles however flawed are important and meaningful. In recent decades, as society has confronted growing separation, fragmentation, angst and anger, the university milieu has also encountered its share of trials and tribulations. Some of these challenges are merely reflections of obstacles facing society writ large. Some of these challenges, however, are somewhat unique to the institution, or at least assume a unique character and condition due to the peculiarities, parameters, qualities and quirks of place. The array of novel negative features that have been building in the academy is broad. For the purposes of the present paper, intending to catalyze future research, the author has identified, and will elaborate upon, five features: Relentless Individualism, Mob Mentality, Power Differential, Popularity Contest and Barefaced Discrimination. Relentless Individualism: The systems in place in higher education promote competition before community, and generally both within the ranks of the professoriate and in student populations. Coates & Morrison[10] (2011), for example, highlight that: "Faculty members compete for research grants and academic prestige; they compete for tenure and promotion, and often for an annual merit bonus; and they work in a complex professional environment, where evaluation is constant, real approval rare, and criticism routine and intense." The milieu, for all stakeholders, can be aggressive with high stakes. Grading scales, pay scales, performance curves, merit assessment, chasing points, pursuing papers, seeking attention, demanding accolades, and the like all tend to foster a milieu of winners and losers. And while, without question there must be means to differentiate levels of success, and to acknowledge progress, such focus on individual advancement should not come at the expense of building community, of cultivating civility and of propagating a culture of caring. In reaction to many institutional developments, including reduced operating budgets, eroding salaries (taken to irrational levels where institutions refer to oxymoronic 'zero percent' increases), and misguided efforts to encourage rivalry, faculty double-down on self-preservation, escalate self-interest and slide into survival of the fittest modes. Relentless individualism is concerned about winning at all costs, aggressively displaying the peacock feathers and assertively keeping others in their place. Mob Mentality: While the concept of mob mentality seems on first glance to oppose relentless individualism, they are in fact mutually supportive. Often individuals fear for their success and progress in a climate

[9] Bennett, John B. Academic Life: Hospitality, Ethics and Spirituality. Anker Publishing: Bolton, MA. 2003. Page 21.
[10] Coates, Ken S. and Morrison, Bill. Campus Confidential. James Lorimer & Company: Toronto. 2011. Page 146

plagued with power plays, where senior faculty with authority can make or break the careers of junior members. Often less outgoing faculty dwell in the shadows of those with voice and influence, being easily swayed to take a side or move with the mob. In academic environments there tend to be very few checks and balances on mis-behavior, and this is especially true as one climbs the ladder in power and position. In many cases there are systems through which to raise grievances, or to appeal decisions, or to express concern – however in many cases these same systems lack substance, enforcement and impact. In many cases the rewards of travelling down a path of complaint are few and far between. In some cases merely raising a matter places a target on one's back – whereby the group is clearly able to rally against the whistle-blower, marginalize the outlier or sideline the opposition. Power Differential: University environments, while frequently taking pride in claims of independence and horizontal structure (e.g., difficulties in herding cats or raking water uphill), tend in fact to be very vertically structured. In many cases the lines of authority are clearly defined, delineated, apparent and applied. In such cases positions and position descriptions, including job responsibilities, are well cast with manifest accountability. However, and far more disconcerting, are the power differentials and power games that exist in informal ways. For example, senior tenured faculty members that have sights set on controlling the behaviors, interests and agendas of junior tenure-track academics. At times the biases play out in the open, at faculty meetings or committee sessions, where intentions may be vehemently verbalized and loyalty expectations explicitly expressed. In a dark observation around power differentials Hollis[11] quotes a junior faculty member: "Untenured faculty are very susceptible to being bullied by their tenured colleagues; the whole system is set up to support that." Far more problematic are passive-aggressive actions whereby confusion and chaos are sown, wherein junior faculty sense they are being judged, or their work is in question, or they are slipping, all without the benefit of overt & objective guidance. In many instances the power differential rears its ugly head in committee deliberations considering tenure, promotion, merit, leave requests, internal seed funding applications, or similar entreaties. In such committees senior faculty tend to wield extraordinary influence by virtue of experience, rank, seniority or connections. They are often leading these adjudications, expressing views, often personal, about the virtues of an academic, an application, an argument, or an advancement. Due to the authority and power (might makes right) imbalance more junior members are often reserved, intimidated and/or acquiescent. While questions about right or wrong may be in mind, it is difficult to challenge those in power and especially if there are demonstrably bad consequences for running against the current. Twale & De Luca[12] underscore: "To acknowledge the power and authority differential is to begin to redefine and redistribute power with an aim to neutralizing a bully and a bully culture." Popularity Contest: Human beings have a natural craving to belong. Our identities are, in part, derived from those we associate with, from those we resonate with, and from those we feel most alike. To be popular is to have a sense of belonging – to feel comfortable and to know we fit in. On the contrary, to reside outside of a social group, to be alone and to be out of place is challenging and discomforting. In the halls of academia there are many cliques, groups and gangs based on common views, shared values and similar posturing. When an academic strays too far from the party line they face risks of alienation, marginalization and ostracization. Such party lines may not be

[11] Hollis, Leah P. Bully in the Ivory Tower. Patricia Berkly: San Bernardino, CA. 2015. Page71.
[12] Twale, Darla J. and De Luca, Barbara M. Faculty Incivility: The Rise of the Academic Bully Culture and What to Do About It. Jossey-Bass: San Francisco, CA. 2008. Page 167

explicitly delineated yet are tacitly understood – for example, subscription to a given view on pedagogy, or particular research methods, or an in-vogue style, or certain internal politics, and the like. When it comes to evaluation, whether for merit, promotion, awards and so on, one's popularity can factor large in decision-making. If professors are outliers, with views that are contrarian, they can be harshly assessed and even punished. Even with the guardrails of tenure, those in power (whether administrative, committee, jury, etc.) can inflict pain and suffering upon those deemed to be assuming unpopular positions. Barefaced Discrimination: Perhaps the most egregious of tactics at play in the academy is blatant, open, unvarnished discrimination. Certainly the academy, as a cultural institution and at the highest levels of aspiration and action, is a champion for fairness, justice and equity. In general, and in many ways, the academy subscribes to and achieves elevated positions around morality and ethics. That said, at lower levels, including internal peer review mechanisms, there are many instances of abuse of power, abandonment of values and simply bad behavior. Of course the academy frowns upon discrimination of all types, opting instead to champion the rights of all members, and all students, in a climate of equality and acceptance. However, when committees need to render decisions, or individual administrators are called upon to take a stance, undue considerations such as gender, age, race, income and other factors can surface. In many cases when infractions are brought to light, by whistle-blowers for example, the system struggles to react in positive ways. Often the legal experts in the system, on both faculty and administrative sides, suggest cases of discrimination are exceedingly hard to prove. Again with almost no means to discipline belligerent behavior, such as demonstrations of overt discrimination, the issues are downplayed or swept under the carpet. The toll of fighting the system, in the case of victimized faculty members, is commonly significant. In the end the odds of winning are slim and the potential risks of precipitating retribution and escalating abuse are many. To sum up … These negative forces, and damaging actions, within the academy are not of course omnipresent but are evident enough to warrant our attention and demand our concern. Shrinking university budgets and growing obsession with things quantitative have tended to translate into growing aggression in the ivory towers, with voracious academics clamouring for anything of substance in the zero sum game. Notions of rating, or ranking, or sorting or sifting, are totally understandable but that said, must be informed by evidence, must be executed with fairness, and must be grounded in justice. Unfortunately in many instances these qualitative judgements are frequently rendered in less than pristine ways, and often without the benefit of unbiased means, metrics or methods.

4. MEANS, METRICS + METHODS

> Peer-Review[13]
> "process by which a scholarly work (a paper or a research proposal) is checked by a group of experts in the same field to make sure it meets the necessary standards before it is published or accepted."

While many of the identified concerns are discoverable in all corners and crannies of the university, some colleges and departments are arguably more susceptible to various forms of bias and discrimination. The design professions, including Architecture, are especially prone to abuse due to the unique nature of the disciplines. Architecture, for example, is a complex melange of art and science, humanities and technologies. Due to the highly subjective dimensions of the

[13] http://www.merriam-webster.com/dictionary/peer-review

profession, judgements around right and wrong, good and bad, strong and weak, often degrade into realms of intuition, opinion, flavor and favor. Unlike more empirically based fields, where measurement and quantification are intensely standardized, architecture endorses and encourages very subjective ways of interpreting, understanding and judging. In architectural design many facets of the equation are more about 'appropriateness' than about right or wrong. A dozen architects working on the exact same problem would arrive at a dozen largely unique solutions – all with greater or lesser levels of appropriateness and suitability to the challenges at hand. One might argue that in the creation and construction of a building this level of tolerance or latitude is acceptable if not desirable. However, in the academy, when decisions are being made that have demonstrable impacts on one's career advancement, research progress, teaching efficacy and so on, the need for fairness, integrity and transparency looms especially large. Promotion of rank or judgements around meritorious performance should not be a moving target based on whim, personalities and politics. Rather, all faculty members should know the rules of engagement and should have confidence that the scales of justice, and modes of judgement, will be fair. The present paper wades into some difficult and turbulent waters. A key goal is to explore some dark corners of the academy – at this point in a preliminary manner that paves the way for more fulsome study. It is worthwhile to briefly review some of the typical approaches to internal assessment of faculty, including the areas normally considered for evaluation. As an initial examination the research aims to be exploratory – in many ways more speculative than definitive. The author acknowledges and accepts that further study will be required, especially in a comparative sense, both within and between institutions. While the evaluative strategies of institutions vary widely (and, of course, differ widely between various countries), and the author is quick to support said nuance, the overall tactics and techniques for review are relatively common within the academy. For example, most universities globally attend to the triad of teaching, research and service, albeit with percentage weighting at times shifting from school to school. The following section of the paper is intended to provide a very general understanding of forces and factors under consideration. Narrative Assessment + Committee Review: In many schools the process of internal assessment, whether for advancement in rank, acknowledgement of performance, or conferring of awards, involves two components. On one hand the administrator closest to the academic in question prepares a narrative summarizing performance and underscoring high and low moments in that performance. This often involves a rather subjective read of an application prepared by the academic under review, which in and of itself is often quite subjective. In Architecture there are few definitive standards that are set with respect to impact factors of journals, weighting of publications, value of research outputs, etc. So to reiterate, a rather comprehensive yet ill-categorized listing of accomplishments by an academic is then interpreted, again in an often loose manner, by an administrator deemed to be the closest supervisor in the hierarchy. The language of such interpretive narratives is often colorful, highlighting the poetic posturing of the discipline rather than underscoring a more fair and objective evidence-based adjudication. This narrative, a summary of an academic's performance as interpreted by an administrator, is then used as a starting point for a committee review. The tone of said narrative often leads the witness – that is, the position of the administrator may unduly influence the committee that is charged with being fair and honest judges of a faculty member's performance. This aspect alone is enough to call into question

or even discredit the system, as it is highly influential and anything but blind. Review committees, often elected by fellow faculty members from the field, sometimes with additional academics drawn from outside, then consider the narrative as a starting point with judgments then strengthened or weakened by review of the candidate's application (e.g., portfolio of performance). These committees are commonly highly politicized, with junior members deferring to senior members and with extroverts dominating deliberations. While these committees are often intentionally composed of tenured and tenure-track professors, the power differential is obvious and difficult. Few tenure-track faculty are willing to confront senior professors, knowing that soon enough the junior members' fate will be in the hands of their senior colleagues. After a decision departs a review committee it is commonly screened again by the next administrator above, typically a dean, who judges that the committee's assessment can be upheld or modified – upwards or downwards. This point in the process demands tremendous strength, integrity and openness by the administrator – or else another point of exploitation can be introduced. The internal systems of adjudication, in general, are often far too tight, intertwined and incestuous for comfort and confidence to prevail. In many cases such committees deliver a judgement on the applicant, meritorious or not, worthy of tenure or not, deserving of promotion or not. While some universities strive to inject as much balance as possible into such systems, in the end the ensuing determinations are often colored negatively by the many flaws inherent in such closed, internal arrangements. The university typically structures review of faculty around a very traditional trilogy of teaching, research and service. It is helpful to briefly consider these realms, and in particular with respect to weaknesses and faults inherent in prevailing methods of assessment.

Teaching: Teaching is a hallmark of higher education and as such weighs heavily under any schemes for assessment of faculty. There are many means to assess effectiveness in teaching. Unfortunately many institutions rely too heavily on only one or two approaches, and most commonly just student executed evaluations (also called course and instructor surveys). There are myriad problems with reliance on a single instrument, and even when they are executed with care and professionalism the results can be misinterpreted and even abused to ill ends. For example, most course & instructor evaluations include scales for questions but also include written anecdotal comments. In reviews, such as faculty performance, individual comments can be extracted without context and without a complete picture. In other words, negative comments can be extracted for the purposes of building a case, even if the evidence points elsewhere. Also, if anecdotal comments are 'cherry-picked' without the inclusion of the full statistics around the survey then the conclusions can be misguided and even malicious. A better approach is to deploy an array of tools to more robustly measure teaching effectiveness – and there are many from which to draw.
Research: Research is a vital activity of the university, with the pursuit of new discoveries and the application of existing knowledge fundamental to equations of success. In so many ways the contributions of the academy, in terms of the advancement of society, the alleviation of suffering, the improvement to quality of life, and other positive actions, are outstanding. Measures of research achievement are many, and in general are fair and appropriate. Impact factors, funding levels, external awards, patents secured and other metrics aim to objectively assess the benefits of scholarly exploration and scientific experimentation. In terms of internal systems of assessment for faculty, at times the consideration of research accomplishments

is reasonable yet at times it is skewed. To expand on the latter, in some cases a faculty member's research area can be viewed negatively by assessment committees or administrators, based on personal opinions or group tendencies.While there are good reasons for the concept of academic freedom, the principle and the practice are commonly out of resonance. Pressures to chase funding – that is opportunistic research – or to conduct research in line with donor interests, can unduly alter any aspirations around fairness and freedom. Also, while strategic areas for an institution and/or a school are important in many regards, they should not be paralytic in terms of faculty who stray from the party line. Judging the worth, impact and importance of scholarly work should be executed at arm's length – without the influence of politics, personalities & popularity.
Service: The final leg of the trilogy is service, with this activity assuming many forms and touching many communities. In some cases the service efforts are internal to a faculty or to an institution, such as a curriculum committee or a university appeals process, but in other instances are dedicated to professional organizations or toward the public sphere. This work can be quite difficult to measure, as in many cases the outputs are less tangible and quantifiable compared with what might be seen in teaching and research endeavors. However difficult to empirically judge, service pursuits are nonetheless a critical part of an academic's contributions. In many schools this work is weighted less than teaching and research, with a common breakdown of 40% teaching, 40% research and 20% service. With regard to internal evaluation perhaps the greatest risk is an overlay of politics into the mix – for example, a faculty member donating time to address human rights, a sustainability agenda, indigenous affairs, or working to lessen homelessness, may be judged negatively if the culture of the school or university runs in counter directions. In some schools such hot topics are seen as irrelevant, or niche, or marginal which then colors assessment of faculty performance.
Conflicts of Interest and Conflicts of Commitment: An area of unease that warrants mention is conflict of interest and conflict of commitment, both of which can negatively shape decision making within internal evaluation schemes. For example, a member on a merit assessment committee could have previously been evaluated for tenure, or promotion, or a teaching award, by the same individual they are now charged with assessing. Such blatant conflicts commonly arise within the academy – again the lack of blind assessment subjects the process to corruption in serious ways. A frequent response by administrators, and legal folks, within the university points to the smallness of the pool and the fact that academics need to simply get along and trust each other. Unfortunately such posturing is foolishly naïve and simply unrealistic. Various forms of conflict are the reality and must be understood and managed as such – the internal processes of assessment need to fairly and objectively consider such conflicts and, in response, demand conflicted faculty to resign from committees or recuse themselves from evident problems. While many schools do have policies and language around such conflicts, the actual discharge of the policy is another beast altogether.

5. AN ALTERNATIVE NIEW | FIT

> "Faculty and administrators with tenured faculty appointments are untouchables and they continuously get away with bullying because it isn't looked at as a termination worthy cause. … The norm is bullies running unchecked devouring the meek and weak in an organizational structure. The bullies pick on those they believe they can bully but won't stand up against someone on equal footing. It is sad to watch." Hollis[14] (2015)

[14] Hollis, Leah P. Bully in the Ivory Tower. Patricia Berkly: San Bernardino, CA. 2015. Page 70.

In light of some of the serious challenges to peer-review internal to our institutions, the author proposes a much more mindful, and disciplined, approach to the processes, policies and procedures deployed. In particular, the individuals and especially the leaders responsible for the conduct and oversight of peer-review need to be vigilant to ensure peer-review is honorable and just. Of course the words are easy to write or say while the actions and operations are difficult and demanding. In the academy we profess to students the need for our societies to be balanced, compassionate, respectful and reasonable. In our classrooms we endeavor to model good behavior and to espouse the worth of a life well lived. We teach theories and principles, and explore application and implications, with care and attention to detail. In terms of our evaluation of our peers, some of these same strategies and objectives seem apropos. For certain the systems of evaluation we enact must be evident, must be consistent, and must be justifiable. Too often decisions are rendered behind closed doors, with directions determined by preference and personality versus by policy and principle. In our research we aim at rigor, validity, certainty and clarity. The author argues that this same set of guideposts should inform our peer-review systems. Exercising narrow agendas, limiting academic freedom, playing politics, abusing power, deferring to the mob, and preferring popularity over performance all have no credibility within the seriousness of internal peer-review. The present paper advances a framework for peer-review that acknowledges the system complexity and recommends careful attention to the triad of Fairness, Integrity and Transparency. Considered together, and if applied with an understanding of their inter-relatedness, significance and vitality, these three dimensions of peer-review have potential to reform and redesign the policies and processes in meaningful ways. Given the tremendous responsibilities we, in the academy, are charged with by society, and considering the great privilege we hold within the education and research realms, we need to get the assessment equations right. Based on explorations of the literature, as well as several decades of direct experience in the academy and senior administration, the author proposes a system for internal peer-review that demands three interdependent qualities. **Fairness; Integrity; Transparency**. These three dimensions (FIT) need to be diligently addressed when formulating principles then developing and executing policy for peer-review.

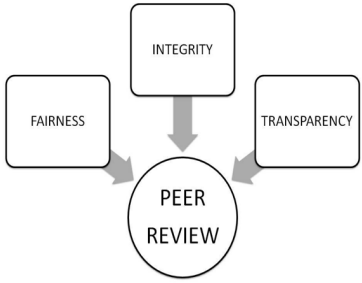

Figure 1. Integrated Framework for Enhanced Peer Review

5.1. Fairness

Fair[15]

- *marked by impartiality and honesty: free from self-interest, prejudice, or favoritism <a very fair person to do business with>*
- *(a) conforming with the established rules : allowed (b) consonant with merit or importance: due <a fair share>*
- *open to legitimate pursuit, attack, or ridicule <fair game>*

The idea of being truly impartial lies at the heart of any peer-review approach. To be 'fair' necessitates some shared understanding of the conventions enacted – in other words, going into an internal peer-review process

[15] http://www.merriam-webster.com/dictionary/fair

both the reviewers and the individual under assessment must clearly grasp the regulations, policies and, most critically, the criteria being used. The focus should be on explicit criteria that can be in some ways measured – it does not necessarily mean that every aspect of the review should bequantifiable, but rather that every aspect should be explainable. The processes and methods should also be consistently applied across those being reviewed. In this case, one size does fit all. When the rules and regulations morph based on personality, preference or politics, the system cannot be fair.

5.2. Integrity

Integrity[16]
- *firm adherence to a code of especially moral or artistic values: incorruptibility*
- *an unimpaired condition: soundness*
- *the quality or state of being complete or undivided: completeness*

The academy is a very special place, comprised of people who largely aspire to do meaningful work with positive impact. In doing this work there needs to be values in place – which, while both implicit (tacit) and explicit (say-able), need to resonate within and across the larger community. Ethics need to underpin the enterprise, including attention to not only the well-being of individual members but also to the fitness of the whole. The notion of a moral compass is appropriate, where each of us can ensure our actions are mindful and our intentions are good. The health of the academy rests, in significant part, on the clarity, relevance of and subscription to such a moral code. Following the code has implications for all of our activities, from teaching and research to community volunteerism and public outreach. It also, of course, holds undeniable connections to and correlations with peer-review. If a faculty member treasures the code and watches the compass, then ill-behaviour within internal peer-review processes should be kept in check. If the code is ignored, and the compass broken, then a trail of damage and destruction is inevitable. Unfortunately there is always tremendous collateral damage in such cases – it is never just the individual under review that bears consequences. The system, as a whole, is assaulted and undermined.

5.3. Transparency

Transparent[17]
- *free from pretense or deceit: frank*
- *easily detected or seen through: obvious*
- *readily understood*
- *characterized by visibility or accessibility of information especially concerning business practices*

As the saying goes, 'The sun disinfects all it touches'. Douglass[18] (1986) noted "Institutions create shadowed places in which nothing can be seen and no questions asked." Internal peer-review, considering its essential place within the academy, must be fully transparent. Not only do the policy and criteria need to be explicit and shared, but critically the processes and procedures therein must be fully understood and visible. The notion of being 'free from deceit' is fundamental. Based on the experience of the author, in many instances decisions around peer-review within institutions are rendered in a black box – rather like the great Wizard of Oz performing his magic behind the curtain. Internal peer-review, whether addressing merit pay, performance assessment, promotion and tenure, or grant money, cannot be a mystery. The rules need to be readily understood and without fail, followed. In many cases the metrics for success, for example in teaching or in scholarship, are

[16] http://www.merriam-webster.com/dictionary/integrity
[17] http://www.merriam-webster.com/dictionary/transparent
[18] Douglass, M. How Institutions Think. Syracuse University Press: Syracuse, New York. 1986.

loosely defined then more loosely interpreted. The value of a teaching assessment, or the worth of a journal publication, should not be determined 'willy-nilly' by any one academic or even by a committee of academics. In the experience of the author, the outcomes of annual peer-review processes within institutions can swing dramatically based solely on the composition of the committee. This is entirely inappropriate. As with any complex system, peer-review is multi-faceted and influenced by a plethora of forces. The aforesaid framework is intended as a guide to direct thinking around peer-review policies and procedures. The value of peer-review within the academy and, by extension and implication, beyond, is unquestionable. We need to be very disciplined, conscientious and decent in the development and execution of rules, processes and outcomes of peer-review. We need to develop peer-review systems that treat all with equality, respect and dignity, and that fosters not only the well-being of our faculty but also furthers the civility and worth of our institutions. academy

CONCLUSION

> "Despite their public representations – and perhaps their inner intentions – these institutions offer a philosophy of atomism, and ethics of opportunism, and a spirituality of self-preoccupation." Bennett[19] (2003)

> "Professors, taken as a group, are far from perfect. They can be petty, foolish, venal, lazy and quarrelsome. Nevertheless, at its best, the university is a remarkable institution. It is a place where ideas are taken seriously; where notions that are taken as givens elsewhere are problematized; where what has seemed to be reality can be bent and reshaped by the power of the mind." Ginsberg[20] (2011)

Peer-review remains a vital and valued aspect of higher education – when it works it ushers in many positive outcomes including the potential to demonstrably raise the quality of teaching, research and service. However, as the present paper delineates, in many instances the system is in disrepair and/or dysfunction. Such problems are, of course, part and parcel of greater challenges facing the academy and society beyond. That said, the academy, and its members, have a responsibility to act at more elevated ethics levels and to behave in ways that inspire and influence our students. There needs to be a fundamental shift away from relentless individualism, abuse of power, and a culture of greed. In its place we need to cultivate a milieu of respect, of caring, of fairness, of civility and of community. Bennett[21] (1998) calls for a move from 'academic professionalism to collegial professionalism. He explains the latter noting "professionalism is converted from credentialism and exclusivity, protectionism, and isolation from others, and it moves to an emphasis upon connectivity and imaginative empathy, competence and dedication to the learning needs of others." There is little doubt that the arrival of negative dimensions of internal peer-review is a product of the greater ethos that rewards and encourages competition before collaboration and presents a 'zero-sum' scenario as the only game in town. The author seeks to open eyes, minds & hearts, including his own, in an attempt to encourage more investigation into very complex and disconcerting aspects of the academy (see also, for example, Sinclair[22] 2019 "The

Devil's Crop). The current explorations are admittedly preliminary and perhaps provocative, with a goal to reveal both obstacles, and opportunities, concerning the realization of a more equitable ethos. The researcher is optimistic that the academy can find its bearings, not only pertaining to the matter of peer-review but more generally regarding its discharge of duty and owning of accountability. To recalibrate the compass requires a concerted effort by academics to be far more mindful of their actions, far more generous with their care, far more reasonable with their demands and far fairer in their deliberations. It also relies on valuable and indispensable players within our institutions, such as faculty associations, ombudspersons, centers for teaching + learning, research services, institutional assessment offices, and units for protected disclosure, to help us stay true and on track. At the end of the day the system, and its constituent members, needs to be more honorable and more just. The present paper outlines concerns with the structure and conduct of internal peer-review and, in response proffers an integrated framework for reform and redesign. This work necessitates risk, courage and openness. Glazer[23] (1999) stressed: "While openness begins as an inner, personal discipline, it very quickly evolves into a dynamic, interactive experience. Our own openness actually collapses boundaries between ourselves and others and the world."

PAPER #7.05

ARCHITECTURAL EXPERIENCED MACHINES: THE ACTIVATION OF TIME

José Manuel Barrera Puigdollersr[a]
[a] Universitat Politècnica de València, Valencia, Spain

ABSTRACT

The optical and kinetic art of the 1960s converged on the architecture of the 1970s with a sensitive and poetic style, with its sensorial imprint making it phenomenological. The semiotic contributions of the same period raised from the theory of reception, the open work of Umberto Eco, the debates on the interpretation between J. Derrida and H. G. Gadamer channeled through the critical work of Manfredo Tafuri, culminated in the hermeneutical contamination of this discipline. The mutations from 'art as activism' to 'activism as art', 'the personal is political' in 'everything is political', the postcolonial theory transferred to 'all minorities', added to the above, provides a scenario of transformation, where activism, participation and politics converge in conceptual art. The architecture unfolds under these signs and the post-conceptual at the end of the 20th century and the direction changes from the search for meaning to the search for experience and in its excess, it is sometimes constituted as experiential devices for activating time. Some works by Miralles and Pinós, Diller Scofidio, Olafur Eliasson, Turrell and Neón Artist, Libeskind, Eisenman, SANAA, Carlo Scarpa, sculptures by D. Bestué, J. Plensa or R. Serra, among others, will allow us to identify the temporal prevalence in the space-time relationship so characteristic of our discipline, and in it to recognize the strategies of temporary mobilization.

KEYWORDS

Space; time; machines; conceptual; post-conceptual.

INTRODUCTION

I see an advertisement on a poster for the facial cream InstaMoisture from the cosmetic brand KIKO, which promotes a virtual investment: that the new look is like the virtual one in Instagram (fig. 1). Here, the virtuality is taken as a simulation of reality (our first photo was already fictitious since it was edited), mobilizes the disintegration of the little reality that remained. A third order virtuality. An activating image of time "How did we come to this? Does the same thing in architecture?" In the extensive bibliography produced (Giddens 1994), we look for indicators to clarify the imprecise transition towards post-metaphysics of architecture, where we appreciate its indistinct implementation in a short, aporetic period, in which these "experiential machines" emerge.
Jürgen Habermas (1980) In view of the preceding (postmodernity), had to remind himself of the establishing of the project of modernity through Max Weber's idea:

> Cultural modernity is defined by the separation of the substantive reason expressed by religion and metaphysics in three autonomous spheres those being science, morality and art that are distinguishable because the unified world views of religion and metaphysics are separated.

In this "false autonomy" of art lays a certain complexity. This agitated debate on postmodernity presented different approaches. For Jürgen Habermas (supporter of the "critical appropriation of the modern project") modernity was a challenge against the cultural order of the bourgeoisie and the "false regulations" of its history. Today it is considered as the official culture to transgress; "It is dominant but dead" as long as it does not practice its unfolding, warning in turn about the "false denials" that happen to it. Facing a new culture portrayed in the 70s by: (1) configuring a new representation scene, (2) employing supreme fictions derived from thinking about difference from a sensible perspective, (3) by its populist masking, (4) with stylistic "avant-garde" that falls on kitsch, (5) embroiled in hermetic codes, with as many models as there are works, (6) without affiliations and easily assignable to apparent relativism. A set of adhesions that caused skepticism towards the autonomous spheres of culture, without being recognized by experts, navigating formal affiliations that led to social affiliations, to finally delve into the political-cultural nexus that in practice formed an activism as art (Felshin 1995, 9-29) (hardcore, which transforms the physical and social environment) and enhances the political reaction. A liberating effect through an aesthetic anarchy, or "utopian dream of a time of pure presence" and a space beyond representation. This display was influential based on conceptual art that tried to "find art in social energies"; a possibility that would allow the expansion of social.[1]

[1] Helen and Newton Harrison–environmental art; Suzane Lacy–feminists performance; Judy Chicago in The dinner party (1979); Mierle Laderman Ukeles–kinectic art; Carol Condé and Karl Beveridge–political activism (1969, 1976).

1. DISCUSSIONS AND ANALYSIS

This trend is possible due to several previous transgressive ideas: a) the historical concept of culture made up of the representational and performing arts, mutates due to the effect of mass culture to approach how the lifestyle is organized and carried out (Bell 1979); b) simultaneously from feminism it is coined that "the personal is political" (Hanisch, 1969). Ideas that in their extensive implementation led to enhance non-cohesive individualism with social structures and with it their segregation that led to dystopia and diachrony. At the time, neo-conservative critics (Shils 1969; 1967) the majority in the Atlantic sphere maintained that this emerging culture "took the form of a struggle from an *oppositional* mindset to discover a new logic" and with it ties the revised concepts to different forms of extremism. Those empty criticisms did nothing but provoke the forcibly autonomous emancipation of art that led to activism, performance, participation, *virtuality* and *kinesic staging*, which in its evolution was seized by the new politics in the construction of new pseudo-cultural identities.

Hal Foster's (1988) gathers a larger sample of critics who announce a "break with the aesthetic field, changing the very object of representation". Or they emphasize postmodernity as the object of post-criticism and the politics of interpretation. Specifically as a new, "schizophrenic manner of space and time, which declares the "death of the subject". From literary criticism Paul de Man points out that each period goes through a modern moment, which is followed by a period of "the transgression of the ideology of the transgressive", to turn it into mutating purposes and thus autonomy into identity. Roland Barthes cites the relevance of continental culture in the transition from structuralism to post-structuralism, where he reflects on "culture as a corpus of codes or myths", as a set of imaginary solutions of real contradictions. The following gathers some common features that define the operational plexus of this postmodernity: c) it follows a textual, narrative, allegorical but contingent model; d) it deconstructs itself to open up to other images, other heterogeneities, rewriting its contradictions, challenging the dominant narratives with the "discourse of others". And so it distinguishes between two directions: (I) the postmodernism of "resistance" and (II) that of "reaction"; the first is of action, the second of diction through rejection and praise, dominated by neo-conservative messengers (Connor 1996; Lyon 1996; Rorty 1996; Rorty 1986; Jencks 1982; Jencks 1981; Bell 1977); e) it will be Jürgen Habermas who points out the common aspect; those factors act strategically, separating the cultural from the social, and then blaming modern problems for social problems; that is, they confuse cause with effect while reaffirming an economic and political status of a new "affirmative" culture. Along these lines, Kenneth Frampton had already warned that historically culture was a force above all of social control that mutated towards a "free image drawn on the face of instrumentality". No wonder, therefore, that the new policy eliminates the control that culture exercises if its intention is to break with the future, history and the past. On the contrary, the resistance groups are interested in implementing post-metaphysical in two ways; (II.1) with a reconstructive bias (as in *dismantling*) and (II.2) (as *disassembly*) the critical deconstruction acting on the traditions that question without presenting cultural codes since it explores them without hiding social and political affiliations. Rosalind Krauss (2013; 2006) points out an important aspect in this position; it is a rebellion of external cultures (to the art in question, painting, sculpture, architecture through politics, feminism, gender, sociology, psychoanalysis, etc.), against the breakdown of internal culture, even in its most exclusive domains (utility, strength and beauty, or

[2] The Marxist left in the 70s revises modernity: Victor Burgin, Jo Spencer, Mitra Tabrizian, Henry Bond, Liam Gillick. Tainted the Next Left. In 1993, "Whitney Biennials" makes official activism.

the equation form + function + meaning in architecture). Gregory Ulmer details that this crisis of representation has led to new cultural forms: a) through collage and montage the conventions of modernity are questioned; b) deconstruction as a critique of mimesis and the sign (Derrida); c) allegory, as a thought *in progress* linked to action, participation, kinesthetic art, etc. (Benjamin); f) other authors (Sánchez 2006) introduce us to a hermeneutical problem (Gadamer and Derrida) derived from participation: if the work is clarified with this mediation or intervention, the personal expectations of the receiver are integrated. For this reason aesthetics becomes a weapon, by extending to all areas "the personal is political", and since personal expectations are integrated in such a way that collective interest is declined. g) For his part, Simón Marchan (2006) introduces us to the duality between *real and virtual* in the rise of techno aesthetics or aesthetics of digital appearance, where references to reality are diluted "in the random games of the signifiers", a hyper-textuality derived from the implosion of signs, which produces a *divide between the material and the immaterial*; or the rise of new antinomies through dematerialization and de-realization. All these shelled factors form the basis of an architecture that converges towards "experiential machines".

2. THE CRITIQUES

Regarding both lines, Fredric Jameson (1996; 1991; 1989) (like Terry Eagleton, I. Hasan, J. Baudrillard) point out that this new cultural form is a guise to avoid our complex present (present-present or eternal present according to the authors). That is, the heart of the problem is focused on temporality. Other discourses cite the transit of intentional time to mere temporality. It is through the *pastiche* "where we swim in a sea of private languages", that satisfy the desire to return to less problematic times. For Jean Baudrillard we are witnessing the dissolution of space and time, because simulation loses cause; and without it there is no unmasking of reality, "the object no longer serves as a mirror for the subject and there is no private and public scene, only information". Such an excess of information is not accidental but opportunist. Edward Said points to a purpose: to establish a "doctrine of non-interference", by which humanism and politics are kept at a distance that allow the second to re-establish a new order that, not being global with the humanistic parameters linked to art, they must be of a different nature; propagandistic, informational, fast-paced and populist. For this reason, the illustrated project is uncomfortable for these groups that question it, seeking to serve other purposes among followers of multiple circles of political-identity. And thus he suggests that contaminations and interference practices are necessary to deconstruct this perverse dynamic through artistic and cultural criteria. Along the same line, Umberto Eco (1968) will express himself, in relation to anti-critical programs in mass culture, where opinion-makers, routines, outsiders, ragmen and scavengers, interview each other, objectifying and constructing virtual anti-social themes. With all this came the displacement of spatiality by temporality.

Thus, through the configuration of a parallel (*unsightly*) network of ideas, meaning is ignored and aesthetic *experience* is shaped, derived from post-colonialist trends (Fanon 2007; 1962; Césaire 2006): ethnic arts, ethnographic twist, multiculturalism, social heterogeneity, whose existence is separate, without object and beyond history (as shown by the new urban contextualism or the landscapes of action born from Land Art as restorations that generate an ecological aesthetic). For this reason, art can produce interactions, inter-subjective relationships of identity and a symbolic totality, which by its separation (also externality to the being of the subject), keeps the subject anchored in the "eternal present", but vested with a new

plexus of alienating political formulations that are presented as new independent stories with supplementary language (as occurs with those abducted). It is what Habermas calls "aestheticization of politics", that occurred with futurism and constructivism prior to the Second World War, and which transformed the enunciated autonomy (*logos*) of modernity into stylistic identity (pathos). A change in the re-appropriation of art or the process of altering meaning through the *aesthetic experience* - so typical of today's virtual world. Because:

> When such an experience is used to ished light on a life history situation and is related to life problems, it delves into a language game that is no longer that of aesthetic criticism. So the aesthetic experience not only renews the interpretation of our needs in whose light we perceive the world. It also permeates our cognitive meanings and our normative expectations and changes the way all these moments relate to each other".

This process has been gaining strength with the modernizing of computers, until defining the time of virtual dominance, described by Slavoj Zizeq (2011). A process that Marchán (2006, 42) attaches to rampant *sociologism,* "which invokes micro-politics of power that tend to postpone the goals of a social transformation for the sake of the exploration of *Myself* where all the personal is placed in the category of the political". However, Derrida is opposed to part of this analysis: because he points out its opportunity as the aesthetic experience allows complete alterity and a hermeneutic of the event, opposing the errors that prevent temporal disruption.

3. THE TEMPORARY TURN

But also, in those years, a conceptual implementation forging transversality was conceived, which, being carried out from that distance of society and history, was the underlying layer of its later problematic situation; (1) from the incorporation of subjectivity it contributes: participation, multiculturalism or acceptance of other logic of meaning, transforming the approaches based on self-awareness (Kant, Hegel), towards positions on moral will (Fichte), genius aesthetics (Schelling); but finally mutating towards subjectivism (misreading Saussure or Derrida) ethically understood as the predominance of the Other, here as pseudo alterity that ends up being aestheticized. (2) "Complex" thinking (Edgar Morin) and lateral thinking (Edward de Bono from cognitive development) were applied to the "processes" of work, discriminating the repertoire (superstructures) that mutates towards the acceptance of multiple logics of meaning. But instead of approaching infinity in a qualitative way, it is replaced by free will: with a possibility of the structural side and alterity on the post-structural side. It was when the cognitive cartographies, the maps of forces, energies and tensions, and diagrams emerged in their two readings; quantitative and qualitative. (3) The theory of processes, (in relation to situationism), through its particular conceptualizations in literary, creative and architectural dynamics, also converge in the incorporation of *significant topologies*, which allow the receiver to act as co-author when participating in the hermeneutic discovery, as well as its desire-driven *invention*. (4) Such a hermeneutical dimension of architecture lends itself to testing the duality between open work and deconstruction, through existentialism and phenomenology. Where the lack of understanding of the deconstructive work resulted in relativistic with no more reach than the synecdoche or the pseudonym. But in any case, the predominance of time over space, known as the *temporary turn* (Brandt 2015), was imposed. Umberto Eco (1975) gives as an example at the Faculty of Caracas of Carlos Raúl Villanueva, 1960; Colin Rowe (1963) approaches as a key element

the "dissolution of limits", through glass, as a temporary device; Superstudio (1967) appeals to "ideas as objects", because these can change time; Paul Virilio, points it out *in Architecture, virtuality and disappearance*; Bernard Tschumi develops it in the Glass Pavilion from 1994-96, challenging instability in a sloping glass box, reflecting the data codes of interior computers. Enric Miralles calls *imaginary machines*, for whom the viewer's gaze reconstructs the time of the project, such as the *Casa Garau Agistí*, the Kolonihaven cabin or the Igualada Cemetery; Josep Quetglas says "as if inhabiting were nothing more than moving between the time of a place" (Miralles 2004, 34); Curtis, indicates his maps of forces and energies, which converge to modify time; Robert Brufau, highlights his *archeology of time* and Zabalbeascoa (2013), calls it *architecture of time*. The objective of this temporary primacy in architecture is to overcome the *prefigured time* through its operation and perhaps the recurring *invention* is possible, not only of the initial author, but of the participating subject successively. Every time we contribute a new signifier to the work it is renewed and updated, able to configure a different future. As Derrida (1998, 347-372) points out for the work as a text,

> Writing is a kind of brand that will constitute in turn a kind of *producing machine*, that my future disappearance will not prevent it from continuing to work and giving, to reading and rewriting"

4. ITS DEVELOPMENT

Since the mid-1980s other factors converge in that initial dissent, which only augment this *temporal diachrony*: the excess of information, the speed that prevents successive adaptation, the high level of alienating demand, the predominance of the video sphere or interactive virtual reality. In other words, "second degree simulations" (like our advertisement) that produce "transitions from traditional spaces of optical illusion to current ones of immersion" (Marchán 2006, 43), *virtual environments, multisensory* works, which generate their own reproductions mimetics. For this reason, these excrescences are overflowing with digital narratives, mediated communication, substituting inter-subjectivity for interaction and subjectivist sensitivity that hinder their real socialization, being replaced by the pseudo-artistic communal experience of a marked sign of private politics; that is, the complete overcoming of the simulation reached by Real (Barrera 2019). Where the marks of space-time "are transformed into virtual figures, things or events" that generate a universalist semiosis —sometimes of impersonation—, whose answer is: "despite the facts, I feel that way." Here, time results from iconic transformation and post semiotic response (transformation of signs). With this, an explosion of referentialities occurs, where the similarity within the virtual field becomes iconic correspondence, which, being a mirror image of itself, passes towards the *hyper-aestheticization of the virtual*. Where we can neither allege the theory of experiential expression, but only "the production of meaning that is altered by metamorphosing itself into the reworking of the stored data" randomly. The works of *techno art* are therefore floating, evolving, interactive, in permanent dissolution, capable of "manipulating the synesthetic system by controlling environmental stimuli" (Marchán 2006, 48). Having overcome hyper-reality, we enter the Lacanian Real (Lacan 1999), which does not belong to either the imaginary or the symbolic order, but which has its own presence and existence, although it is not representable. It is the place where the signifiers of foreclosure reappear or return in the form of hallucinations or delusions.

5. EXPERIENCED TIME ACTIVATION DEVICES

They are parts of the project, encounters, forms, sequences or routes, materials, optical, haptic, or sound supporting the multiplicity of experiences leading to the questioning about time. They unfold on the basis of an activist architecture, symbolically, socially and politically, or in their encounter with space; endowed with participation, inter-subjectivity, with a predominance of paradoxes and antinomies or resources that in its interpretive reading allows multiple annexations and grafts; they form significant concepts. We recognize the architecture that displays the diversity of these devices as *experiential machines, virtual environments,* imaginary machines or producers. The devices created serve ten modalities; social time, phenomenological, aesthetic, material narrative, psychological, hermeneutic, eventual, semiotic, memory and virtual time. We acknowledge the following trends:

5.1. Re-figured time

The fifth generation of Modernity (second to postmodern time, 2nd PMT) emerges and is set between 1980-1995. It stands out for the empowerment of the discourses described through two transitions; the specific importance that *the image* and *the story* acquires, in the terms that Ricoeur (2008, 148) quotes while "the story or the plot… refigure an action in time" because, "we continue, then, the passage from a prefigured time to a refigured one through the mediation of a configured one" (the one that we imagine could be subject for debate). Those two transitions will destroy the inherent space-time relationship of the architecture, to turn to the temporal primacy, the *refigured* time. Introspective glances seek inner clarification by extracting unsuspected, invisible relationships in a substantially transformative creativity. Through significant transversality, investigative themes are introduced, such as the fold, plateaus, rhizome, the fractal, etc., which allow the participative, activist, integrated, collaborative praxis of the subject in the work experience. With it, a hermeneutical turn, between narrative and poetic; because "what is interpreted in a text is the proposal of a world in which I could live and project my own powers" (Ricoeur 2008, 153); that is, making it narrative *re-signifies* the world in its temporary dimension. Because dynamism, activity and participation transform aesthetic experiences into life experiences. Faced with this "poetry, by its *mythos*, *re-describes* the world" (Ricoeur 2001). In this the communicative scope of the image is explained, in the fight against the surviving image (pathos) that Didi Huberman (1990) exposes, as the structure that appears through form, or "invisible tension that confronts visibility"; latent forces of the past that are presented; Aalto (Schildt 2000) already pointed out that "what has ever existed, always reappears in a new form". This overvaluation of memory, like its disconnection between image and story, allows old ghosts to emerge, which in Derridian terms, would be the *symptom*: "falling together", a word that means first the sinking, the collapse, then coincidence, the fortuitous event, the encounter, "the other way than being" (Derrida 2003; 1987). Its impossibility of re-allocation lies in the mixture of polarities or antinomies, and its overlapping in movement tending towards the activation of temporality. Álvaro Siza (1995) will call it "a fusion agent", the cause of transformation or *union*, in the ambivalent transition from synchronic to diachronic. And this despite the fact that the priority option of poetics is autonomy, autarky, loss of hierarchy, break with conventions or the discovery of possibilities, which nevertheless end up in new alienating identities; Also called "inversion of motive" (Baseliz, 1984), *simulated savagery* by Dahn (Marchán 1984, 446) or as Jean Baudrillard (1978), "simulating is pretending to have what one does not have". This transformation will successively establish a supposed new

iconographic modernity, autistic and devoid of a story (neither social nor personal), which apparently will have the signs of that one but which pretends to have what it does not have. Its devices are, time and narration, aesthetic time, hermeneutic, eventual.

5.2. Re-signified time

At the turn of the century and the first decade of the 21st century, together with the growth of provocative post-structural responses, (mistakenly disclosed under the shadow of deconstruction and formed through the implosion of the object, the multiplication of volumes or the plastic decomposition[3]) is configured by the sixth generation of modernity (6th gM) between 1995-2010 (3rd PMT), various alternatives to these drifts within the same; through *liquid* architecture and the will to formalize the *destructuring* in proposals constituted in temporary activators or *disconnected* experiential machines ', all of them through action. The architecture of Miralles had rehearsed multi-temporality, as Gordon Matta Clark did, in its cuts and holes in obsolete dwellings, the re-activation of time, giving them an opportunity to show their hidden reasons for their foundation; Olafur Eliasson, reproduces time in overlapping narratives that look mirrored. Diller Scofidio raises the evanescence of time through the blurring of form in steam; and SANAA, from their poetic *dissolution of limits*, allows the work to be circularly changing like its concern. The 'representation of time' by the sculptor David Bestué, in his exhibition 'Rosi Amor' (2017), aims through the accumulation of objects that make up a disorganized memory - fragments of ruins and remains - to represent linear and the centrifuged time, "as if time were just another substance and could also change shape and turn to dust". All this in a work of internal symbolization to action, since according to Ricoeur (2008, 156),

> it is re-symbolized or de-symbolized —or re-symbolized by de-symbolization— thanks to the schematism sometimes turned into tradition and others subverted by the historicity of paradigms. Ultimately, it is the time of action that is truly refigured by its representation.

Its devices are: eventual, psychological, narrative, aesthetic, semiotic and hermeneutical time.

5.3. Recoded time

But another more structural line is needed that longs for a certain return to those foundations of modernity, exhausted from the osmotic ideologization of the marginal contents that had politicized all creative displays through their narratives. Thus, two routes emerge with a certain importance and in parallel; I) on the one hand, a *neo-formalism*, (opposed to experiential machines) that, as in post-conceptual painting (Marchán 1972), evokes a certain satiety with the previous excesses so belligerent: the expressionist tectonic (even technical brutalism) as a priority response of the previous generation: Foster, Piano, Rogers, Ito, Sou Fujimoto, among others within the structural line. Such neo-formalism addresses some common variables, such as a certain synthetic formal expressionism, vernacular features interspersed with a geometric, compositional and monochromatic reductionism, an instrumental and practical rationality, which is based on the power of hidden structural solutions, arranged as if it were nothing. This formalism recovers previous personal poetics in the shadow of the last masters such as Louis Kahn, or that shown by Siza Vieira, Lina Bo Bardi, Adalberto Libera, José Antonio Coderch, recovering that spirit of Gastón Bachelar (1957). It is in the form of phenomenological dialectics, "as a study of the phenomenon of the poetic image" recalled by the architectural space. We do not say represents, simulates, mimics, seems, recomposes, but its scope is established in

[3] David Bestué (2016) anticipate the keys.

the *recalling* of mnemonic memories, and with them the virtual ones. Its devices are: phenomenological time, memory, material narrative, and hermeneutics. On the other hand, II) with certain structuralist doses the continuous line of social *commitment* is developed (reluctant to let the experiential machine denote different signs of materialism),

> taking a position and real commitment to all forms of connection with the problems of social environment, the only way out of the quality of the marginalized, imposed by the superstructures of the system.[4]

It is a line that sacrifices capitalist evocation and the liberal discourse implicit in technical-functional benefits, for the discourse of technical sustainability, as a giver of quality or human value. Thus they recall the most radical positions of Radical Architecture, 1965-75. To do this, they must do so without the usual means of production, or with the standard channels of communication, but through their tactical use.

This line will strive to create new information channels, and new forms, according to their recipients. All displays will be produced by *occupation* (ideological-political act of the medium) of the space, showing its contradictions. Their responses are not merchandise, but work, *co-creation* and materials, provision of services, disarticulating the economic-cultural relationship even for their part-time work and alleging the lack of work to their fellow believers. Like Santiago Cirugeda (2020) of an anti-system character. From ideological marginalization they oppose the system: he is a worker-intellectual-artist linked to a process of transformation of the relations of artistic-cultural production -their tools of resistance, direct interaction and non-verbal communication. Faced with the metaphors, or *"informal translations"*[5] of the previous line, the "blockade between different symbolic universes" is considered '. Or in another way, without mediation, producing messages for no one in particular, latent in the video sphere. In this line the new millennial generation or Gen Y: with late works by Lacaton and Vassal, and the young Izaskun Chinchilla, Uriel Fogueé, Andres Jaque, Ecosistema Urbano, Zuloark etc. Its structuralist underlay comes in this case from its political appeal, as visible as it is prone to the "pro-common", with proposals such as *urban endodontics*. Its temporary devices generate psycho-political experiential machines. The following temporary devices are used; social time, psychological time and hermeneutic.

5.4. Refraction time

In the second decade of the 21st century, with generation Z (7th gM and 4th PMT), all open lines are maintained, but under two transformative effects; the complete unfolding of the *video sphere* and the tiredness and *dissatisfaction* that traditional and reinvented sociopolitical discourses generate. Applying these two factors assumes that their *authenticity* fades because instead of making conscious proposals of their full scope, they are mediated not by their experience or the author's experience, but by the virtuality of such borrowed experience. Thus, the eventual autonomy germinates in an inexorable identity. They do not intend to establish spaces and times of their own experience, but to offer a reflection of virtualities that in turn mirror mnemonic images of other people's experiences, impossible to make their own. This leads to design *refraction* (the action is refigured by the representation, Ricoeur said); It is designed following apparent images of force, which in reality exhibit the remains of other things than those pursued, from an unconscious consciousness. In it, time

[4] Response from Marchán (1972) to Tapies' article
[5] Joseph Kosuth in "One and Three Chairs" (1965): "The art I call conceptual is such because it is based on an inquiry into the nature of art".

disappears, anchoring itself in the *eternal present*. Hence the invasion of simulations, impersonations, *freaks*, or the distorting mirrors of Eco (2012, 34), "semiotic projects through strange prostheses that generate hallucinatory functions". Such hallucinatory effects are more evident; the more political idealism underlies the structure. Its devices are mainly virtual, material, psychological and hermeneutical.

5.5. Reactionary time

The most *reactive* line against that unfolding is manifested in the "alienating neo-formalist poetics" that emerged earlier, but that is now deformed by nonsense. And this, because it escapes from the previous prefigured assignments; It is not completely structuralist, nor is it post-structuralist. It is basically reactionary with everything, but it is comforted in this *hallucinatory-experiential* drift to which subordinates or personal stories lead, seeking a return to the essential and contained. Here the activation of time is no longer relevant. This pseudo-poetic line supported by the sensitive and defined by images indebted to its power, extracted from the force and formal energy that material plastics have, contains certain mutations like most of the video sphere's time architecture towards *experientiality* different from *experience*; its ideality. This means suffocating the project to a lesser repertoire of signs that make the personal pseudo-poetic visible in an apodictic way, which leads to *figuration*. This is the reason why an eclectic or *prêt-à-porter* reading period is presented, where a wide sector of professionals wanting to occupy a space, with cloned images of variants on the same and with few nuances that extends like a new *international panorama*. Heterodox group that articulates the so-called post-conceptual art, known in Spain as the "new Madrid figuration" or neo-metaphysical art. Defined as post-abstract and anti-realistic, it is driven by *hybrid and unorthodox images*. The exhibition "Painted Architectures" (2017-18), curated by Juan Cuellar and Roberto Mollá, testifies the *dissolution of time* to this creative line. It participates in that melancholy and historical exceptionalism that Gerhard Richter highlighted, when he describes this aesthetic as one that retains the material form of an object whose previous historical function indicates other functions and another context of scope as irremediable; thereby revealing the *"representations of representation"*.

CONCLUSION

The temporary turn of the 80s brings to architecture an entire display of formal, material, haptic, optical, and phonic constructs that, in the manner of semantic tropes, inoculate projects, mobilizing time. According to its development, it incurs one of the five described modalities. The re-signified time and the re-figured time allow ideological neutrality, the displacement of the subject with its personalities and it resembles the poetic unfolding from a semiotic perspective. The rest contain transgressions of some order: imaginary, real or symbolic. Especially highlighted is an ideological contamination towards two trends: recuperate the neo-Marxist materialism at all costs and on the other hand, the liberal current, fed up with such impositions implored by ideology, allowing for contamination of the market. Both unfold to the virtualities that present a desired world.

PAPER #7.06

AWOL: PSYCHOLOGY, BUSINESS + RESEARCH IN CONTEMPORARY ARCHITECTURAL EDUCATION

Brian Robert Sinclair[a]
[a] School of Architecture, Planning + Landscape, University of Calgary + sinclairstudio inc, Canada

ABSTRACT

Architectural design today is a wickedly complex and dauntingly difficult undertaking. The ethos for design activity has grown more complicated, with building and urban projects mired in legal considerations, political expectations, cultural dimensions, environmental demands and financial limitations. Architectural education desperately attempts to keep pace with the present milieu and, under ideal circumstances, to predict future circumstances. The pedagogy required to adequately prepare tomorrow's architects must, by necessity, be agile, resilient and potent. Students must not only learn technical competencies, but must be conferred the abilities to think critically, to anticipate change, to be culturally sensitive, and to be environmentally responsible. Such a deep and broad set of aspirations is not for the faint of heart. The present research, in many ways a first step forward within a broader research agenda, critically examines architectural curricula from a vantage point of societal preparedness. The paper provokes both a broader and deeper understanding of the complex landscapes of design education, with a focus on North American systems. An argument is made, based on meta-analyses and literature reviews, that present-day architectural education is deficient in three major ways. Absent without leave in modern design education & training is understanding concerning human-environment interaction (e.g., environmental psychology), business acumen (including financial awareness & fiduciary responsibility) and research skills (including both quantitative/qualitative methods as well as the need for a knowledge base to advance and apprise practice). While concerns around the subjective nature of architectural production are longstanding, patience is growing thin concerning lack of empirical grounding in design decision-making, irresponsibility in budget management of projects and arbitrary judgement around suitability, quality and appropriateness of design solutions. The author argues that psychology, business and research are key missing ingredients that must be meaningfully introduced into the curriculum. While the paper uses North American higher education as a case, relevance & implications reach out to international jurisdictions beyond. Given urgencies around climate change, health crises, global conflicts, racial injustice, resource depletion and political decay, it is essential for future architects, regardless of geography, to be educated in more meaningful, appropriate and effective ways.

KEYWORDS

Architecture; education; systems thinking; culture; complexity

INTRODUCTION

> "We must take on the work of facing our fears, opening to intimacy and vulnerability, and opening to the unknown, to surprise. We can learn to open to situations simply, without aggression or defensiveness; and open to the inside as well; the depths beyond the surfaces of all life." Glazer[1], 1999

[1] Glazer, Steven (Editor). The Heart of Learning: Spirituality in Education. Penguin Putnam Inc.: New York, 1999. Page 247

Over the past several decades we have witnessed, as global societies, a rapid increase in the severity of calamities and an exponential escalade in the complexity of our world. There are many reasons for these dramatic shifts, including the prevalence of information technology, the ease of mobility and heightened confusion around ethics. While it is undeniable that our world has always been a melange of good and bad, right and wrong, and fair and unjust, recent developments arguably put the equations off kilter and place crises on steroids. From rising conflict and erosion of human rights to climate change and pandemics we confront many unprecedented problems that challenge our conventions and threaten our existence. In earlier days many problems were grounded in local conditions and manageable both in terms of our understanding and our solutions. However, in contemporary times problems become catastrophes with increasing frequency, and often reside beyond our comprehension and outside our ability to act. Historically, universities have played important roles in society, including educating future citizens, discovering new knowledge, and serving as a sounding board & informed critic considering the past, the present and the future. Freedom of thought and freedom of expression provided academics, and by extension students, with a milieu in which to critically consider our many paths and manifold possibilities. The autonomy of the institutions translated into abilities to question the status quo, to develop alternative ways, and to imagine a different tomorrow. Within this unique environment, academics and students have been able to develop novel ways of seeing, thinking and acting that have, over time, ushered in many advancements for our people, our communities, our companies, our governments and our nations. In earlier iterations of the academy, and its curricula, the formulas and the factors seemed simpler and more straightforward. However, in our modern times burgeoning data, information and knowledge engulfs us and commonly overwhelms us. In an effort to fast-track learning and manage growth we have seen increasing specialization, departmentalization and fragmentation. The notion of a well-rounded liberal arts grounding has been dissolving, with many students now channelled quickly from high school into disciplines via direct entry programs. The value of a common core within undergraduate education has diminished, with many students locked within the walls of their baccalaureate degree for their full time at university. In many ways this pigeon-holing makes management sense given the complicated nature of higher education. However, the author argues it makes limited sense with respect to preparing future citizens to grapple with the wicked problems they stand to inherit. We need to be broadening and deepening understanding, versus being overly obsessed with narrow training and pursuing job-readiness. The present paper considers architectural education within the shifting conditions of society and given the context of new demands on higher education. It errs on the side of provocation and speculation, understanding that doors need to be open to tackle pedagogical and curricular reform. The author accepts that such preliminary posturing, by both necessity and invention, is exploratory and challenging as opposed to proving definitive and set.

1. BACKGROUND

> "The longer one listened to him, the more obvious it became that his inability to speak was closely connected with the inability to think, namely, to think from the standpoint of somebody else. No communication was possible with him, not because he lied but because he was surrounded by the most reliable of all safeguards against the world

and the presence of others, and hence against reality as such."[2] (Hannah Arendt 1977)

In the bigger picture, architecture as a discipline and profession is a relative latecomer to the academy. With roots in the guild system of Europe, with the architect positioned as a informed craftsman, knowledge was held tightly and wielded with cautiousness. In time, with the formalizing of knowledge, the role of the master builder was separated into two distinct yet complementary realms – that of the engineer (Ecole Polytechnique) and the architect (Ecole de Beaux Arts). Polarization of positions was a natural tendency. On one hand the engineer was concerned with function, pragmatics, science and technology. On the other hand the architect was focused on form, poetics, art and humanity. The means and methods of these two divisions evolved in unique directions, as did their status and standing in society.

Clearly many of the distinctions drawn between engineering and architecture are stereotyped, with caricatures developed to simply describe the roles and responsibilities of each. That said, there are real differences in the ways these groups are educated, in the values they hold and in the manner in which they problem solve. The present paper addresses the path of the architect within the academy and within broader society with an eye to understand the present circumstances and to chart some directions forward that are productive and worthwhile. The paper is most concerned with serious curricular deficiencies in place that arguably limit the architect's ability to make a profound impact and a positive difference to a world in dire need.

2. ARCHITECTURAL EDUCATION - COMPLEX + WICKED

"In that context, and in practice, the process of individual creativity was imbued with a certain utopian potential and intrinsic positive value and universal social dimensions. Today, however, that 'creativity' is reduced to a caricature of aesthetic forms, expressionistic objects or sculpture –
and is mobilized in the service of the dominant power structures."[3] (MacDonald, 2014)

Architectural education arrived late into the university compared to other fields such as theology, the humanities and the sciences. Coming from a guild and then atelier tradition, the discipline of architecture was at times difficult to understand and place within the accepted structures of the institution. Sometimes placed in art departments and sometimes housed in engineering colleges, architecture programs tended to be seen as niche and quirky. When located in art schools, the architects were viewed as objective and disciplined. When embedded in engineering faculties the architects were seen as subjective and unbridled. Perspective, of course, matters. With the increasing demands of accreditation imposed on the education of architects came heightened uniformity in the substance of the curricula and in the training of future professionals. Accreditation sought to set standards and improve quality control within the educational preparation of architects. Accreditation organizations, such as the National Architectural Accrediting Board (NAAB) in the USA and the Canadian Architectural Certification Board (CACB) in Canada, endeavored to develop guidelines to ensure consistency of content and parallel education of architects regardless of state, school and situation. A key goal was ensuring the competency of individuals while

[2] Arendt, Hannah. Eichmann in Jerusalem: A Report on the Banality of Evil. English version of the 1965 edition. Penguin: Harmondsworth. 1977. Pages 48-49.
[3] MacDonald, Robert. Foreword. In: Design for a Complex World: Challenges in Practice and Education. Graham Cairns – Editor. Libri Publishing: Oxfordshire. 2014. Page vii.

acknowledging the diversity of schools and permitting some freedom of expression.

Architecture, as a pursuit and profession, has increased dramatically in complexity. This heightened complexity ironically has been accompanied with narrowing limits to the scope of practice and a proliferation of allied disciplines within the building industry. Post-WWII architects had a relatively wide role and an impressive range of responsibilities, including in many cases work covered today by engineering disciplines. Over time, with the tendencies of society towards greater specialization, architects relinquished many activities, choosing to focus more narrowly on the 'art' of architecture. Today the scope of the architect in North America has been greatly reduced, with some government legislative bodies arguing they should not be in the business of 'licensing artists'.

3. ABSENT WITHOUT LEAVE

> "A connected curriculum would encourage the integration, application and discovery of knowledge within and outside the architecture discipline, while effectively making the connections between architectural knowledge and the changing needs of the profession, clients, communities and society as a whole."[4] (Boyer, 1996)

Without question, the education of an architect is a long, complex and demanding exercise. Architecture is a unique field in that it resides in the nexus between art and science. While a profession in its own right, Architecture is a complex melange of other disciplines, borrowing principles and practices, theories and actions from allied realms. Invoking the rigor and empiricism of science on one hand, including structures and strengths of materials, while straying into the poetics and subjectivity of art on the other hand, including aesthetics and a quest for beauty. Engineers and scientists view architects with suspicion due to the indeterminate aspects and relative subjectivity of the field. Artists perceive architects with equal misgivings, driven by a sense of the architect's finite approach and overly objective manner. Architects then dwell in this space of the in-between – neither hard science nor fine art, but perhaps a touch of both. As relative newcomers to the academy, architecture programs continue to find a forced fit in many ways. With a limited knowledge base, or at least one that is poorly delineated and infrequently acted upon, architecture is seen by some as more vocational than scholarly. While the education of architects has been refined over decades and perhaps centuries, the methods of teaching, the core of knowledge and the nature of the fit within the university remains controversial. In looking between schools of architecture in North America one is struck by commonalities, informed in large part by somewhat prescriptive accreditation standards and regimes. Whether at the undergraduate or graduate level, the diet of courses and studios is quite similar. At the heart of the teaching model is the studio, an intensive small group teaching method that relies on a master-disciple relationship and the instilling of tacit knowing. Rather than being formulaic, in a glass box sense, the studio is often an ethos of exploration, iteration, creation and testing, that is at once praised for its effectiveness and criticized for its inefficiencies. University administrators often lament the resource intensive quality of the studio, in many cases categorizing it as a lab versus a class. Surrounding the studio is a rich array of courses, in some instances referred to as 'support' courses, which serve to buttress design thinking and ground creative endeavor. These courses tend to be both stand alone ventures as well as offerings more meaningfully integrated into studio. The author has written widely about studio education, including studios that are evidence-based, culturally-focused and also comprehensive.

[4] Boyer, Ernest L and Mitgang, Lee D. Building Community: A New Future for Architectural Education and Practice. Princeton: Carnegie Institute for the Advancement of Teaching. 1996.

While the precise composition of curricula varies in some ways from school to school, the basic foundation of the education proves remarkably alike. Within accreditation there is some latitude provided for schools to celebrate their own DNA, and to express the school's character, perhaps most notably through the spectrum of electives offered. Some schools take pride in a digital focus, some in a design focus, some in a cultural focus, etc. Even with this ability to express uniqueness, accreditation demands ensure that no school deviates too far from the party line. In some ways this is understandable and positive – that is, in the assurance of quality, competencyand consistency. In other ways the accreditation overlay serves to limit experimentation, suppress identity, and restrict agility + adaptability. In reviewing the curriculum of schools at a meta-level, and considering both USA and Canadian accreditation systems, the author contends, albeit and admittedly in a preliminary and speculative sense, there are three serious and arguably debilitating omissions: psychology, business and research. In the view of the author these three areas of study are urgently needed as architects enter the workforce to confront unprecedented problems and cope with an ethos of upheaval, uncertainty and unrest. Each of these three curricular realms will be examined in detail, including some speculation on impacts through exclusion.

3.1. Psychology

Architecture is neither a fine art nor a hard science. It is, however and arguably, a social art that is first and foremost human-centric. A building is not a pure piece of sculpture – it is, to the contrary, a container for dwelling, working, playing, living, etc. Architecture exists for use by people and as such demands of the architect a solid understanding of people – their needs, their desires, their concerns, their aspirations, etc. Evidence shows that buildings, spaces and places influence, impact and inspire people. Churchill once stated that "We shape our environments and they in turn shape us". The directions of such influence can be subtle or glaring, and positive or less so, including architecture's ability to help us to heal, to improve our productivity, to amplify our learning, to heighten our happiness or to repress us. Studies have looked at notions of place, including place-making, place-attachment and place-identity. The places we live in, that we grow up in and that we have affinity for, play significant roles in the ways we view ourselves and our world. Architects have great responsibility to get design as correct as possible when it comes to human comfort in the built environment. In order to achieve such goals, the education of architects must include curriculum addressing environment-behavior studies, environmental psychology, urban sociology, cultural anthropology, etc. Many opponents to inclusion of such content in architectural curricula point to an already overcrowded array of courses on the student's plate. However, to keep such human-centric knowledge out of the education of architects is to deny the true nature of architecture as an ethos of inhabitation. It is simply irresponsible to graduate an architecture student without a solid understanding of how people react to and behave in buildings. It is neglect of duty to send students out without deep awareness of design's capacity to impact lives for better or for worse. Some schools claim this content is captured in architectural programming courses or curricular modules, which has some aspects of reality but which alone proves woefully inadequate. All schools of architecture should have dedicated courses addressing human behavior in the built environment. And in the same way that structures are often integrated into studio, environmental psychology should be a mandatory dimension of studio education. Architecture schools do not need to go it alone – they can and should collaborate with programs in psychology, sociology and anthropology. Such collaboration is both helpful and healthy, in many ways.

3.2. Business

Another realm of knowing that is commonly absent in architectural education is business – business principles, business practices, business knowledge, business acumen and so on. While many graduates of architecture schools go on to work in private practices, or eventually start their own firms, few leave the university adequately skilled and equipped to succeed in the business end of the profession. Looking over almost any school's curriculum one is hard pressed to find serious content addressing business knowledge, short of small modules embedded in professional practice offerings. While studio is the heart of the education of architects, and building designs (almost all new constructions) are the subject of the vast majority of studio exercises/ projects, very few schools require business assignments within said studios. For example, it is rare to have students run pro-forma on projects they are designing. In few cases do studio instructors require cost estimating, even order-of-magnitude, or take-offs to be addressed. Most commonly students are given free reign with respect to the cost of projects, the nature of materials, the energy loads, etc. Certainly the hypothetical aspects of studio are understandable. However, at least some of the studios within a student's program of studies, should be intensely grounded in the realities of cost, practicality, viability and buildability. Without doubt some studios should and must be free to explore the fantastic, the futuristic, the spectacular, the unbound and the unbridled. However, tempering such necessary folly must be experience in meeting budgets, in ensuring constructability and in fostering fiduciary accountability. At present such aspects of education are few and far between. Money is often seen as an unpalatable subject that contaminates the purity of the pursuit of design. Business is often seen as a burden in the curriculum and is knowledge best left to the profession to push into interns and associates as they learn the ropes. Architectural education, however, must attend to business knowledge within the confines of the degrees. The architecture schools do not need to cover this content alone – they can and should partner with business programs in exploring how architects can be equipped with skills needed to flourish financially in practice. After all, if an architectural firm is not liquid how can they realistically pursue their true desire to design & construct buildings?

3.3. Research

Due in part to the character and composition of architecture, and to an extent its public mystique, there are longstanding concerns and criticisms around the shallow nature of the discipline's knowledge base. Many decisions in design are rendered in ways that other fields view as thin or suspect. Such approaches may include intuition, tacit knowing, iteration as experimentation, precedent studies, etc. While these strategies can be, and often are, potent in their own right they tend to be insufficient given the complexities and responsibilities of contemporary building design and construction. The terminal degree in the field (e.g., BArch, MArch, etc.) has, for a very long time, been an acceptable entry into the ranks of the academy. While on one hand, historically, this was an appropriate posturing, in recent decades the call for greater research activity, higher research funding, more impactful research discoveries, etc. has clearly disadvantaged many schools of architecture. The academics within architecture programs have often struggled to secure grants and execute serious research projects, much to the chagrin of senior administrators. And while the author is quick to acknowledge the value of curiosity based research and the worth of design as research, in the present milieu architecture professors can and must do more. This inadequacy in their own research skills and acumen has naturally had demonstrable impacts on architectural curricula. In many schools the pursuit of research by, and the

imparting of research skills for, students is seen as a distraction at best and irrelevant at worst. Even in so-called research studios, or within regular studios that call for the conduct of research, this research work usually comprises only internet searches based on some key words or design precedents. Few students in professional programs (note: research or thesis programs are a different situation), whether at the undergraduate or graduate levels, have a solid grasp of qualitative and quantitative methods, know how to read and apply research findings to their design work, or even how to search periodicals for articles and papers that might strengthen their problem solving. Clients and governments today demand greater accountability and higher performance, including expectations around the deployment of evidence-based design. To be fair some professional programs contain or retain thesis components to their BArch or MArch (or DArch) programs – and in numerous instances such programs do underscore the need to deeper, more thorough and more thoughtful investigations. However, such programs tend to be in the minority with many programs opting to abandon time-intensive thesis projects in favor of migrating towards course-based curricula. Even within course-based programs, and in light of an absence of accreditation criteria mandating any real research content, there are few if any research courses and limited cases of studio engaged in what most universities would deem to be actual research. The author argues that, for many reasons, schools of architecture must include research courses, research skills, research ethics and research impacts as part of the education and training of future architects. Aside from meeting societal expectations, building research skills in our students will undeniably place them in a more competitive position to contribute to firms, to contribute to the profession, to contribute to the industry and, in the end, to contribute more meaningfully to society.

3.4. To sum up ...

Without a doubt it is a daunting challenge to have a faultless curriculum – one that is complete, one that is robust & resilient, one that covers all professional & societal needs and one that fully prepares students for graduation. The author in no way claims that any curricula can be perfect, but rather has aimed to identify perhaps the most glaring gaps in architectural curricula in North America. The selection of Psychology, Business and Research as the most pressing deficiencies in present day education of architects serves to highlight the most evident areas in need of attention – that pertain to the human-centric nature of the built environment, to the need to be financially responsible & solvent in the conduct of practice, and to meet the serious responsibility to make decisions, design and otherwise, based on evidence, facts and reality.

4. FILLING IN THE GAPS

> "In spiritual education the world comes alive. Living and education become inseparable. Self and the world become inseparable. Something is always happening that can be learned from. The only things that are required are openness and attentiveness: the allowing and examination of direct experience." Glazer,[5] 1999

Much debate has transpired over the years concerning the worth and tactics around accreditation. For sure many benefits accrue in pursuing and ensuring accreditation regimes, especially considering that in North America the profession of architecture is regulated – scope and in many cases, title are enshrined in and protected by statute (legislation). In exchange for the privilege of restricted practice, the profession, in our case architecture, must ensure competency. This competency is fostered through numerous mechanisms, including critically the delivery of sound and

[5] Glazer, Steven. The Heart of Learning: Spirituality in Education. Penguin Putnam Inc.: New York, 1999. Pages 136-137

effective education by schools of architecture. Accreditation shapes the content, consistency and consequences of education across jurisdictions, meaning that disparate schools in far removed locations produce graduates with comparable knowledge, skills and values. The author is not raising issues about the value of accreditation but does encourage the arrival of criteria (e.g., student performance criteria) and conditions that capture psychology, business and research as indispensable ingredients to a potent education in architecture. At present, in both the USA and Canada, language and intention around these three vital subject areas, in any meaningful sense, is largely vacant. In considering the robustness and tactical landscape of the architecture curriculum, it is important to understand that the most critical aspects revolve around preparedness for anticipated conditions. It is, in the author's view, insufficient to remain too connected to the past or to be too obsessed with the present. On the contrary, contemporary society is under rapid pressures to twist and turn based on unanticipated developments, demanding & dynamic needs, and shifting expectations. In order to prepare students for an uncertain tomorrow it is especially wise to build a curriculum that hits the main points. The author's inclusion of environmental psychology, business principles and research acumen, into the diet of modern architectural education, attends to this urgent need for relevancy, responsivity and capacity. The following realms pertain to an approach to curriculum building that considers indeterminacy and uncertainty.

Comprehensive Knowledge:
While the education of architects cannot be complete in exhaustive ways – time and resources operate against such grandeur – it should prove comprehensive, spanning divides between art and science, the general and the specific, the poetic and the pragmatic, the subjective and the objective, and so on. Architecture is unique, as has been previously noted, in its dwelling in the nexus of many disciplines, principles and practices. In many ways, to the author's mind, an ideal education should be comprised of a liberal arts undergraduate degree followed by a professional degree in architecture. Over these two components it is reasonable to develop knowledge that is professionally focused while also providing a well-rounded based (that contributes to awareness and responsibility on the citizen side). In those cases where the curricular sequence differs from this ideal, it is contingent upon individual schools to develop a curriculum that is comprehensive on one hand and balanced on the other.

Strategic Nimbleness:
Advanced education is not the same as technical training. Of course many critics have argued that architectural education is out of place in the university, and might better be directed to technical schools. However, the counter argument revolves around the intense complexities of contemporary society and its accompanying problems. Modern day crises are not merely about technical matters – including of course climate change and global warming. The wicked nature of problems that architects face, and not merely building challenges, demand far greater depths of understanding than technical training alone could ever provide. Many dilemmas today are as much political and cultural as they might be technical in character. Architecture students must not simply be inculcated with facts and figures but must be educated in how to learn with nimbleness and potency. Knowing where to find answers is as strategically valuable today as simply knowing answers. The explosion of data and information has made the prospects of knowing all exceptionally slim. In fact, Socrates once mused that "wisdom is knowing you know nothing". Today we are well advised to teach our students that they cannot know everything and that survival, in a professional sense, demands an ability to know

what you don't know and then determine how best to move forward with such understanding.

Professional Competencies:
In North America the profession of architecture enjoys a special status within society – depending on jurisdiction title and/or scope are protected to varying degrees. This basically means that the profession is allowed to operate in a 'closed' fashion through a guarantee of competency. In other words, the gravity of the work of designing buildings warrants extraordinary care to ensure user health, safety and welfare. To meet this expectation of competency the architectural profession deploys a multi-stranded approach, with one strand being accredited education thatcovers realms of expertise required to practice architecture. These professional competencies are numerous and serious. Relative to the present paper, the author argues that beyond the currently categorized competencies the areas of psychology, business and research must be addressed. The author is an architect and psychologist – from this vantage point he argues the societal expectation for welfare is transcended to encompass wellness. Buildings today must tackle more than egress in the event of fires – they must support inhabitants physically, socially, psychologically, culturally and even spiritually. In order to rise to this level of 'well-buildings' it is crucial for students to be equipped with competencies spanning much broader and deeper than was the case in previous decades.

Societal Understanding:
One only has to look at the past few years to grasp the volatility and unpredictability of our world and its nations. Countries that were deemed leaders only a few years back are now in chaos and turmoil. Nations that were not on any radar a few decades back are now major players who cannot be ignored. Governance that was stable a generation back now appears to be unfolding and unraveling. Polarization of populations, the rise of mob messaging and disdain for the rule of law all loom large in our lives – the university needs to prepare students to grasp such conditions and to act in positive ways to move us ahead. This obligation, and opportunity, should not concern itself with a student's major or their degree – rather, all students regardless of college, department or discipline need to be prepared to act upon graduation. With respect to the present paper, the author argues all students and all faculty need to be aware of shifting sands and should be able and willing to make a difference. The call for inclusion of psychology, business and research buttress the skills and knowledge of architecture students in weighty ways that will better equip them to tackle some of the messy problems that await them upon graduation.

Ethical Posturing:
Finally, and not the least consequential, is the need to instill in students a moral compass to help them find their way in the torrent of noise and distractions of modern day societies. The author has written widely about the need for building a strong awareness of moral action and ethical behavior within the academy (see, for example, Sinclair 2019 "The Devil's Crop") – in both the professoriate and the student body. We live in an era where lines between right and wrong are more and more blurred, the understanding of good and bad increasingly confused and the value of facts and truth decaying and dissolving. Architecture students, being educated to operate within a legislatively protected profession, have extraordinary expectations around ethics. Architectural associations, at regional levels and at national scales, clearly delineate and subscribe to codes of ethics. A solid grounding in such affairs needs to be established within architecture schools and their curriculum.

5. HOLISTIC EDUCATION IN AN ETHOS OF CRISES

> "In the beginning, new ground must be carefully prepared; the old growth and underbrush removed; the soil tilled and raked; seeds planted; fertilizer spread; water provided in adequate amounts; while the sun provides ultraviolet and infrared rays creating a warm environment. When all this has been done through long hours of labor and required intervals of germination, a new young tree emerges. Eventually this young tree will bear fruit to reward those who have labored in the vineyard. It would be foolish to chide those who are preparing the soil and planting the seed because there is yet no fruit. It would be unwise to water too much or allow the sun to parch the land. When the time has come, the fruit will be ripe and its substance will sustain those who harvest it. So it is with knowledge." Eberhard, 2007[7]

University education is not in its primary mission about training. Rather it is more rightly concerned with the discovery of knowledge, the instilling of wisdom, and the ability to effectively and creatively solve complex problems through the application of both (i.e., knowledge and wisdom). While in some instances (for example in the case of professional education) there are aspects of skill development and occupational training that need to be addressed, the fundamental focus remains on higher level thinking and more theoretical/philosophical ways of understanding our world. Advanced education, perhaps more now than ever before, must assume the leadership required to educate a next generation of students who can critically examine widespread suffering, who can imaginatively see beyond the status quo, who can devise high-impact mindsets, methods and models, and who can garner the strength and assume the risks necessary to right a ship gone widely off course. In the author's view this challenge should begin with a reconsidered system that includes, in pervasive and transcendent ways, the features of ethics, integrity, competency + wisdom. Taken together, as an integrated system, the pursuit of these qualities should better equip students to cope with a tsunami of negatively and a mountain of incomprehensible problems. This approach assumes that these features find

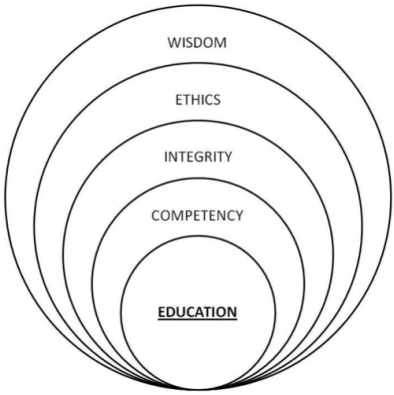

Figure 1. Holistic Model for Higher Education in a Complex World

meaningful fit and resonance within curriculum regardless of college or major. In other words, all programs of studies within the academy would set performance goals that holistically incorporate ethics, integrity, competency and wisdom. Within this mix perhaps wisdom stands out as the most challenging yet the most crucial. The researcher views wisdom as the coupling of head and heart. The university finds great comfort in affairs of the head yet struggles to embrace matters of the heart. It is easier to quantify and rationalize intellectual realms, whereas emotions present territories of uncertainty, indeterminacy

[7] Eberhard, John P. Architecture and the Brain: A New Knowledge Base From Neuroscience. Ostberg | Greenway Communications: Atlanta, GA. 2007. Page 19.

and the unknown. That said, both the pragmatic and poetic need serious adoption and conflation in order to solve modern crises and avert catastrophes downstream.

CONCLUSION

> "The essential difference between life and a machine is that a machine eliminates all idleness and ambiguity. It is constructed entirely on the basis of physical connection, functional, rational principles, and efficiency. In contrast, life includes such elements as uselessness, ambiguity, the unknown and idleness. It is a flowing interrelation continuously creating a dynamic balance." - Kiso Kurokawa[8] (1995)

Architectural education, and indeed advanced education writ large, is in urgent need of reform and redesign and in particular in ways that better equip graduates to address levels of turbulence, trials and tribulations unprecedented in severity and consequence. In considering the education of architects (within North American higher education systems), the present paper has delineated many circumstances, demands, obstacles and opportunities that should be factored into equations for teaching and learning. The author delineates, in an initial and exploratory sense, some of the dimensions of such education yet underscores further investigation is both warranted and timely. Attention to the curriculum in accredited schools of architecture illuminates critical deficiencies that, if left neglected, hold promise to further erode the profession and weaken its practice. Of special interest in the present paper are three realms that straightaway require introduction and integration into the curriculum of architecture schools (both accredited and not): namely, psychology, business and research. While the author acknowledges, by way of a caveat, that some schools do include aspects of these disciplines and spheres of knowledge, there is not consistency in substance, intention and content across the academy. Accreditation regimes must more aggressively define and delimit courses and student performance criteria that attend to student understanding of human behaviour in the built environment, of business principles + practices to ensure financial responsibility & stability, and of research methods and means essential to both the discovery + appropriate application of new knowledge. In our current times, where we face climate change, global pandemics, social unrest, escalating conflict and growing gaps between people, to name but a sampling, it seems urgent for architects, and architectural education, to be better prepared for an uncertain, confusion and risky tomorrow.

PAPER #7.07

DESIGN RESEARCH AND A SHIFT IN ARCHITECTURAL EDUCATION AND PRACTICE

Ayşe Zeynep Aydemir[a], Sam Jacoby[a]
[a]Royal College of Art, London, UK

ABSTRACT

Research, once associated only with academia, now equally connects to learning and practice in architecture, as focus has shifted towards a wider design research community. Research has become inclusive of formerly marginalised areas such as process-oriented and practice-based research in the arts and humanities as well as applied commercial research undertaken by industry. Providing a first study of this shift, this paper explores why design research is of growing importance to architecture. It systematically analyses a selection of current cases at the intersection of architectural practice and education within the UK to survey existing design research approaches, and asks: How can design research transform and create new architectural practices and forms of education? Following this question, the paper discusses some of the design research models used across architectural practice and education.

KEYWORDS

Design research; architectural education; architectural practice.

INTRODUCTION

Research in architecture has long been associated with design research (Archer 1978, Frayling 1993, Till 2005, Geiser 2008, Fraser 2013). Known as 'architectural design research', it highlights the design and research processes and outcomes useful for the creation of projects or a broader contribution to design thinking (Fraser 2013). This definition corresponds with new agendas and frameworks by international research institutions in support of a diversification of research and knowledge exchange.

Design research is increasingly recognised as essential to disciplinary development and architectural education and training. For example, it is one of architecture's core research activities (Rendell 2013) at both graduate and undergraduate levels. In 1999, the Bologna Declaration (Joint Declaration of the European Ministers of Education) caused a shift in education policy within Europe towards research in design-oriented disciplines (Geiser 2008). In the following years, design research in architecture was internationally acknowledged and included within the UK Research Excellence Framework (REF), the Excellence in Research for Australia agendas, and the research framework of the European Association of Architectural Education (Fraser 2013). This year, the European League of Institutes of the Arts (ELIA) presented the Vienna Declaration on Artistic Research to support the establishment of research in all disciplines of art practice including architecture.

Architecture is regarded as a research discipline in its own right (Till 2005), and research is considered to be essential to architectural practice (RIBA 2014c). In 2016, the Royal Institute of British Architects (RIBA) received the highest number of submissions to the President's Awards for Research (RIBA 2017), revealing a growing interest not only in academic research but also by architectural practices to secure funding to conduct research. Therefore, the research community

and audience have become larger, and the distinction between academia and practice lessened. Moreover, the scope and scale of the topics covered expanded and diversified in 2016, while previously most research was project-focused and technical in nature (RIBA 2014c).

Considering these changes, this paper studies how design research transforms architecture. Part of a larger study, this paper will discuss how design research affects architectural practice and creates new forms of education. Based on a survey of current practices and studios within London in the UK, it will further provide a more detailed analysis of selected cases and the differences they present of how design research is understood.

1. HOW DID RESEARCH EVOLVE IN ARCHITECTURAL EDUCATION AND PRACTICE IN THE UK?

For the UK Research Excellence Framework (REF) that replaced the previous UK Research Assessment Exercise (RAE), the definition of research changed from 'an original investigation undertaken in order to gain knowledge and understanding' (RAE 2005) to 'a process of investigation leading to new insights, effectively shared' (REF 2019), with several interim modifications occurring between 2001 and 2019. A comparison of these definitions shows a significant transformation in the understanding of the value of research and the research community over the last two decades. The change also indicates that there is a shift in focus from the academic community to a wider audience, the public. Design research is becoming more important with this shift, as it tends to have a direct impact on practices and practitioners and is directed towards a larger public audience and not just academics. Furthermore, there is a growing emphasis on the process of research and how it is shared, while at the same time still meeting the criteria of 'originality', 'significance' and 'rigour' used in the assessment of research quality. The new definition manifests that world-leading research can include formerly marginalised areas such as process-oriented and practice-based research in the arts and humanities as well as applied commercial research undertaken outside academia in industry.

Research is associated with postgraduate-level programs in architecture and a requirement specified by the RIBA. The RIBA criteria for Part 2 (master level) UK courses in architecture, which it validates with the Architects Registration Board's (ARB), emphasise a 'critical understanding of how knowledge is advanced through research to produce clear, logically argued and original written work relating to architectural culture, theory and design' (RIBA 2014a, RIBA 2014b). This criterion unfolds the significance of research in architectural education by identifying it as a necessity to advance professional practice.

Design is also increasingly regarded as important in higher research degrees. Some institutions have started to define PhD-level projects through design research, often coined 'PhD by Design', 'PhD by Practice', or 'Practice-based PhD'. For example, currently nine PhD programmes with practice-based pathways in architecture are advertised online within the UK by the Architectural Association, Edinburgh College of Art, Goldsmiths (University of London), Royal College of Art, The Bartlett (University College London), Manchester School of Architecture, University of Edinburgh, University of Nottingham, and the University of Brighton. At the same time, most other universities offer an option to integrate design research into PhD work.

In parallel, there is a growing interest in securing funding for research by professional practices. Architectural practices typically apply for research funding by collaborating with a university or as part of a knowledge transfer partnership (RIBA 2017). The new definition of research for the UK REF, which

is run by UK Research and Innovation, and an expansion of subject coverage for quality-related funding from the UK research councils are encouraging practice-based research. This expansion supports architecture – which is deemed unique as a subject and a discipline (Rendell 2004), as it brings together different modes of research that are often kept apart – to develop practice-based and practice-led forms of research and provides possibilities for new interdisciplinary research.

Architectural design research and skills are also recognised as essential to economic growth. Design skills contribute 12% to the total UK gross value added, and their contribution to the economy rose by 47.2% in the architecture and built environment sector from 2011 to 2015 (Design Council 2018). In particular, architecture schools significantly contribute to a growing pipeline of design skills that benefit not only the design economy but the UK economy as a whole. According to the RIBA Education Statistics of 2016/17 (RIBA 2018), there is a long-term growth in the number of student applications to architecture schools. However, the Design Council reported in 2018 that 82% of people with design skills gained in architecture and the built environment, work outside these disciplines in other design roles (Design Council 2015). It shows that the current skillset of architecture graduates is also effective in other industries.

To summarise, one can say that architectural design research in the UK is currently encouraged by the REF definition of research, RIBA and ARB programme validation criteria, a PhD-level focus on practice-led and practice-based research and the UK research councils' quality-related funding eligibility criteria. Furthermore, the contribution of design skills gained in architecture and the built environment studies to the UK economy is recognised as essential.

2. CURRENT UK LANDSCAPE IN ARCHITECTURE: PRACTICE, RESEARCH, STUDIO

New models of learning and practicing in architecture are encouraged and reformulated through collective processes of learning and design research (Geiser 2008), which address an audience beyond just the academic studio and professional practice (Lawson 2002). New learning and practice approaches consolidate the emphasis of the UK REF on research process and impact, an understanding of research that can be seen reflected in the professional architecture course validation criteria of the RIBA and ARB.

In recent years, architects have become progressively interested in design research in both their practice and teaching as well as the wider societal impacts it can create. Practitioners are increasingly taking part in postgraduate-level teaching as studio tutors, are involved in funded research projects and participate in exhibitions and publications. Design studios thereby provide a valuable ground to test activities at the intersection of learning, research and practice. To study this in greater detail, the paper considers necessary the following survey of postgraduate-level architectural design studios.

In the UK, there are currently 44 Schools of Architecture offering RIBA/ARB Part 2 validated courses at master's degree level. The professional advancement offered by Part 2 studies seems to attract the majority of students after passing their Part 1 and having taken a year out. The number of students entering RIBA validated Part 2 courses in 2017/18 was 2,167 (RIBA 2019). This number grows slightly year on year, but for the academic year starting 2017, it is below the number of graduates who completed their Part 1 studies in 2015/16 (2,973). The number of new entrants from outside the UK to first year Part 2 was 734. Thus, around half the students passing their Part 1 in 2015/16 examination must have decided to continue

Table 1. Postgraduate architecture programmes and studio units leading to professional qualification (ARB/RIBA Part 2) in selected schools of architecture in the 2019/20 academic year.
AP: Architectural Practice, UK: UK-based, CP: Conventional Practice, T: Teaching, R: Research, I: Impact, Int: Interdisciplinarity

Part 2 studies in the following year after having taken a year out for Stage 1 practical experience (with a minimum 24 months work experience required before taking the Part 3 examination and fully qualifying as an architect).

London has the leading postgraduate architecture schools using design research and to analyse the current landscape of architectural design research in higher education institutions, three schools of architecture are selected among them. Choosing the Architectural Association, the Bartlett and the Royal College of Art provides a cross-section of leading schools of architecture within very different contexts. The AA is a private non-research institution, the Bartlett is one of the major centres for

research, and the RCA is a research intense art and design school with only postgraduate students.

In the 2019/20 academic year, there were 48 units/design studios in postgraduate architectural programmes leading to professional qualification (RIBA/ARB recognised) at the Royal College of Art (13), The Bartlett (University College London) (14) and the Architectural Association School of Architecture (21) (Table 1). In these studios, the total number of associated practices are 60. 89% (43 of 48) of the studios are run by architectural practitioners, of which 63% (38 of 60) predominantly work on building design, therefore, can be considered 'conventional' architectural practices. 63% (38 of 60) of the practices are based in the UK and 50% (30 of 60) of them state that their teaching is an integral part of their practice.

75% (45 of 60) of the practices explicitly refer to research as a learning strategy or associate their practice with research. 32% (19 of 60) of the practices define their practice as interdisciplinary, and 55% (33 of 60) frequently disseminate their work through publications and exhibitions to reach a wider public. All these numbers are based on the written statements given by the practices within their separate practice descriptions online. However, it is likely that more practices see their work fall into categories of practice-based research, interdisciplinarity and engagement with public audiences. Thus, these numbers are only an estimate of the current research landscape within postgraduate architectural design studios in parts of London.

3. HOW CAN DESIGN RESEARCH CONNECT ARCHITECTURAL PRACTICE AND EDUCATION?

Research-led teaching in the MA Architecture programme at the Royal College of Art (RCA) is one of the prominent examples connecting learning and practice in a Part 2 course. Validated by the RIBA and ARB since 1983, the programme philosophy responds to RIBA criteria by fostering independent postgraduate research and experimentation in design with a strong connection to practice and the material reality of the discipline.

In the 2019/20 academic year, the MA Architecture programme offered 13 different Architectural Design Studios (ADS) that resonate with the key research themes of the School of Architecture: Architecture and Social Movements, Institutional Forms and Practices, Intergenerational Cities and Climate Justice. As stated in the Programme Specification 2019/20, each ADS has unique thematic interests and offers a 'Live Project' in alignment with their studio brief and agenda. The ADS structure is based on peer learning, with first- and second-year students working alongside one another. Furthermore, second-year students are required to prepare an Independent Research Project, which is tutored through the ADS and relates to its specific research agenda and studio brief.

ADSs provided a valuable context for this study. In parallel to the programme philosophy, all ADSs at the RCA are run by professional practitioners, and 69% of them are associated with 'conventional' architectural practices (9 of 13). Based on how they describe themselves online, all of the studios explicitly use research as a learning strategy, or they associate their practice with research; 46% (6 of 13) of the studios define their practice as interdisciplinary and 61% (8 of 13) of the studios frequently disseminate their work through publications and exhibitions (Table 1).

To understand better the intersection of learning, research and practice, ADSs in the MA Architecture programme at the RCA were observed during their introductory presentations, Work-in-Progress show and the RCA2020 graduation show in the 2019/20 academic year. In the introductions at the beginning of the year, ADS tutors presented fully-developed briefs suggesting a variety of themes, sites, methods, schedule and external collaborations, which later reflected on the studio outputs exhibited in the work-in-progress and graduation shows.

ADSs differ in terms of their process-driven, output-driven and impact-driven focus. To discuss these different strands of design research they represent, ADS3, ADS6, ADS9 and ADS11 were selected for further observation during their pre-exam reviews before the Final Examination. Observations were undertaken on different days within a remote learning environment due to Covid-19 outbreak measures. For this study, only second-year students' work was reviewed, which were 22 presentations in total. 68% (15 of 22) of these students completed Part 1 in the UK and 32% (7 of 22) had gained their undergraduate degrees outside the UK.

During their pre-exam reviews, all students presented their work in the format of a research book, a design portfolio and slides, and often an additional medium relevant to their studio focus. Examples of this medium are a web platform, an Instagram page, a short film, a simulation, or a digital animation. Students introduced their design research process, stating a research question, methodology, a project brief and a design proposal, often including multidisciplinary considerations. The importance of these elements differed according to the studio approach adopted by ADS tutors.

ADS3 'Refuse Trespassing Our Bodies: Metabolising the Built Environment' is run by Daniel Fernández Pascual and Alon Schwabe of Cooking Sections. Cooking Sections is a research-based practice that explores the overlapping boundaries between visual arts, architecture, ecology and geopolitics. In 2019/20, ADS3 investigated synthetic pollutants and explored the spatial implications and circular trajectories of these substances. Similar to Cooking Sections' own design research approach, all studio projects addressed issues of locating and investigating a present pollutant, and tracing and bringing into view their spatial implications as well as their sociological, political, metabolic, environmental and ecological impact. Consistent with their chosen dissemination models, students presented their work through performance, mapping and video. Cooking Sections' practice model sets an example for design research with value to policy making and promotes an artistic focus in the studio work.

ADS6 'The Deindustrial Revolution – Garden of Making' is run by Clara Kraft and Satoshi Isono of Kraft Isono, and Guan Lee of Grymsdyke Farm. Kraft Isono is a multidisciplinary film and architecture studio, whereas Grymsdyke Farm is a research facility, fabrication workshop and live-work space that was established by Guan Lee. In 2019/20, ADS6 studied the theme of deindustrialisation and students explored potential contradictions and inconsistencies of human and non-human ecologies in relation to craft and making. The projects varied in spatial, temporal and practical contexts, as did the methods of investigation, which made use of performance, field recording, 3D scans, archival material, poetry, models, prototypes, interviews and photography. All students produced animations and films as part of their studio outputs. Diversity in topics, locations, tools and methods as well as multiple iterations and rigorous use of animation brings together the multidisciplinary approach and specialisation of Kraft Isono and the research and fabrication background of Lee. Their studio focus underlines craft and making as a design research approach.

ADS9 'Aura – A Call for Open Architecture' is run by John Ng, Zsuzsa Péter and

James Kwang Ho Chung. All tutors are practicing architects and Ng also runs a multidisciplinary practice called Elsewhere. In 2019/20, ADS9 investigates architectures of openness with a particular interest in the modes of co-existence. The students' projects explored various spatial contexts and scales in which design proposals can achieve societal, political, cultural and economic impact. Students developed their work through material experimentations, spatial explorations and environmental analysis, and presented their work through web platforms, models, poetry, videos, collages and architectural drawings.

ADS11 'Already There' is run by Renaud Haerlingen and Victor Meester of Rotor with Livia Wang. Rotor is a cooperative design practice that investigates the organisation of the material environment. They have a spin-off project called Rotor DC that facilitates the reuse of construction materials by dismantling, conditioning and selling them. In 2019/20, ADS11 examined practices of deconstructing existing architectures, working with a series of sites and collaborators to develop an understanding of the methods and design possibilities deriving from dismantling and reuse. Students investigated the regeneration of Aylesbury Estate in South East London. Their various proposals involved experimenting with hyper-density, inclusive renovations and reclaiming dismantled materials. The life cycle of materials, residents survey, speculations, learning from demolition, construction and renovation processes were their tools and methods of investigation. Rotor's and Rotor DC's influence is highly present and creates a practice-based focus in the studio outputs.

Evidently, ADS3, ADS6, ADS9, ADS11 tutors have different approaches to research in architecture. ADS3 have a process-driven, artistic focus aiming impact on ecology and geopolitics. ADS6 also have a process-driven research understanding, but they prioritise craft and making through various medium. ADS9 has an output-driven research understanding with a focus on wider societal impact, whereas ADS11 has a practice-based focus with a specific interest in dismantling and reuse. However, design research is an integral part of connecting their teaching and practice in all of them. Their practice methods highly influence the studio works in terms of research topics, research methods, project development and outputs.

CONCLUSION

Over the last decade, professional practice and research and learning in architecture have become integrated. This recognised a new international understanding of research and a growing importance of design research, which has fostered interdisciplinary collaborations, new research communities and a wider societal impact. Several factors drive this transformation and can be summarised as follows:

- Expanded subject coverage and range to include design within established research frameworks.
- Expanded subject coverage and range to include design in quality-related funding from UKRI research councils.
- New validation criteria by professional bodies in support of research.
- PhD-level focus on practice-led and practice-based research projects in higher education institutions.

This study shows that practitioners that internalise design research in their teaching and practice represent a majority among tutors of postgraduate architecture design studios in London. They have either process-driven or output-driven strands of design research, they are interested in creating wider societal impact and they are highly influential. Further studies are essential to analyse how this influence and growing importance of design research transforms design practice, learning and research in architecture. One

area of research is to conceptually frame and analyse the difference of research processes, outputs and impact in practice and academia. Another is to undertake qualitative research to understand how different practitioners experience design research and the transformations it brings to industry. Therefore, following this paper, a critical reading will be undertaken within a conceptual framework and structured interviews will be conducted with practitioners to study these influences in greater detail.

ACKNOWLEDGEMENTS

PAPER #7.08

RENEWING DESIGN PRACTICE VIA A DIACHRONIC STUDY OF TEKTON AND ARKITEKTON PRACTITIONERS

David N. Benjamin[a], Jonas Holst[b]

[a] better, Inc., Burlington, Vermont U.S.A. / Sivilarkitekt MNAL, Oslo, Norway

[b] Claustro de la Instituto Humanismo y Sociedad Universidad San Jorge, Zaragoza, Spain

ABSTRACT

The Architect Peter Clegg, of Fielden Clegg Bradley Studios remarked to me in 2006, that it is the very practice of Architecture that needs to be reformed, not just the designs, forms and materials used for construction. This paper will review opportunities for different reform processes and networks, focused on renewing and incorporating into current design/construction practices, cooperation and authentic work with construction craftspersons as co-creators in Design Participation Teams or Conservation Participation Teams. The paper will review the history of such practitioners from European history, such as the Tektons and Arkitektons and look at possible cognates in non-Western cultural histories. Historian Jonas Holst, at Universidad San Jorge has written an important introduction to these key members of the construction team in history: The *Fall of the Tektōn and The Rise of the Architect: On The Greek Origins of Architectural Craftsmanship*, published at the EAHN website: https://journal.eahn.org/articles/10.5334/ah.239/ This paper will further review current practitioners that have taken on these roles and how other Architects can work with these professionals or take on these roles/responsibilities themselves.

KEYWORDS

Participation; tekton; arkitekton; intangible heritage; sustainability.

INTRODUCTION

Despite claims, made by this conference convening committee, that a new generation of architecture students and practitioners, "….is characterized by…. an inclusive, transversal and revisionist nature," which includes, "….feminism, gender, childhood, shelter, migration, wealthy, transversality, glocality, interculturality, multiculturality…." This set of idealistic concepts seems to leave out what we propose are key members of the Design/Conservation Team (DPTs or CPTs), who deliver the built environment, such as the craftspersons performing the making of settings and artefacts. Further, the above list of concepts seems to be overly ambitious and would be difficult for most individual designers and craftsperson to fully encompass, understand, let alone take on and authentically accept. The conveners further challenge this conference and the profession to: Explore the role of the city and regain the, "….leading role that architects should have in its design.While some authors have proposed a more nuanced view of the Architect's actual and conceptual leading role,[1] we agree that the Architect (or *Architekton* in ancient Greece and in pre-Socratic Greece, or *Tektons*, sometimes

[1] See for example Foster, Hal. 2013. The Art-Architecture Complex. London: Verso. in toto and the review by Rowan Moore in The Guardian, The Art-Architecture Complex – Review. Published 16. September, 2011 accessed 27. Feb., 2020 https://www.theguardian.com/books/2011/sep/16/art-architecture-complex-foster-review

written *Tektones*), as an individual player and as representing the institution of the profession, do play relevant and helpful roles in the building professions. Architects often do work as an intermediary, multi-disciplinary 'bricoleur' and advocate for the interests of the diverse group of community stakeholders, landowners/clients, the aesthetics/beauty and environmental health and welfare of the built environment and the general stability of the planet's ecology. As one way of regaining the "leadership" role in designing cities and of maintaining the key relationship to the urban peripheries (and we would add rural regions and wildernesses), we propose to work at enabling and enquiring reflexively into the *reformulation* of the profession of architecture itself, mainly through authentic efforts at inclusivity, listening, active questioning and reflective interaction and collaboration with all the members of the DPTs and CPTs. . This includes opening up to learning and teaching in convivial and collaborative relationships with often neglected members of the profession, for example skilled crafts- and tradespersons and their associated institutions which make the physical objects from the designers' concepts.

We furthermore propose that this inclusion of all members of the construction sector, including skilled tradepersons, into the multifarious working process of architectural practice is in line with its own age-old traditions, across many different cultures, places and time periods, even up to the present. For example, many well-known Architects in ancient Greece and Rome based their know-how on the archaic arts of tectonic craftsmanship, including their conceptual-intellectual knowledge and also, the knowledge, creativity, manual dexterity, and facility with formulating buildable, repairable and common-sense constructions to further programmatic and aesthetic purposes, or to use ancient terms, their senses of *phronesis, techne*, and *ars* (the ancient term for productive making, which came to be known as our modern "art" with its more aesthetic connontations)[2]. Most of these Architektons, were first-class craftsmen themselves, who possessed a detailed hands-on knowledge of materials, their selection, prudent material combinationsand highly developed, diverse manual dexterity skills, to cut, shapeand combine materials in order to create well-wrought buildings, landscapes, infrastructures (fortifications, roads, and so on), and interior furnishings. , They also mastered over many years of *apprenticeship* and *mastery-as-practice*, the essential skills of being auto-didacts while at the same time having the humility and 'teachability' to apprentice to older experts during their early training. Many of these individuals even had their own forms of inclusivity, in their acceptance and cooperation with migrant craftspersons from other racial backgrounds, cultures and nations, such as the mobility of craftspersons between the Mycanean, ancient Greek and Levant regional cultures, which contributed to their skills mastery and their ability to organize, design and construct structures with remarkable components, such as the 100 ton lintel blocks of some Mycanean monuments (approximately 90.7 metric tonnes).[3] These crafts/design mastery *communities of practice* helped lay the foundation forthe flourishing and maintenance of new and diverse Mediterranean societies, up to, during and beyond the time of Homer, or the 8th Century, B.C. . At some point,, from approximately the middle of the 6th Century B.C. the building projects, which came to define the landscape of the Hellenic and Roman world, became so large that new leading supervisors were needed to project, oversee and orchestrate the whole enterprise. The *tektones* became

[2] See Blockley, David. Practical wisdom and why we need to value it. OUPblog. Published July 11, 2014. https://blog.oup.com/2014/07/practical-wisdom-vsi/ accessed 27. Feb., 2020.

[3] See the articles on Ancient Mediterranean Civilizations and Architecture, for ex: https://en.wikipedia.org/wiki/Mycenaean_Greece accessed 29. February, 2020 and Burkert, Walter. 1998. The Orientalizing Revolution Near Eastern Influence on the Greek Culture in the Early Archaic Age. Cambridge, MA., U.S.A.: Harvard University Press. (rev. ed) ppg. 9 – 24.

architektones, the leaders of craftspeople, the organizers of the construction works, acting as liasons to the procuring powers and socio-political hegemons financing the works and as designers of the structures.Since this rupture in ancient Greece a gap has opened up within construction sector, between designers, craftspeople and, at some point in the 19th century, engineers.

Leaving out skilled trades- and craftspeople from architectural practice and the broader DPT/CPT group of collaborators, as often happens today, thus creates anunfortunate and unnecessary rupture within architectural practic itself between designers and engineers, on the one hand, and craftspeople, on the other hand. The rupture thus seems to have contributed to a cleaving of the functional roles and status levels of the ancient Tektones into three legally defined institutionalized 'professions'. Following the ancient etymology of *Architect*, Αρχιτέκτων,[4] it could be said that the leaders become separated from the people of craft and trade, thus cleaving αρχή and *tektōn* in to two. [5] This rupture or separation often leads to delays and mistakes in the working processes and even sometimes lead to an antagonistic relationship among the members of the design and construction teams. It is not out of a nostalgic desire, or normative historicist motive, to revive ancient and historical era traditions that we bring tectonic craftsmanship into the discussion in order to 'heal' this relationship. Rather This enquiry stems from a sincere concern for architecture as a multi-faceted discipline, containing a rich variety of knowledgeable professionals working together, based also on a diversity of current practical and scholarly efforts: These include several applied scientific and artistic research efforts and work in the design research and professional practice of architecture fields.

Examples include several scientific fields actively seeking out research questions and learning from the past, as in the multi-disciplinary Climate Culture Catastropher Network ,[6] led by archaeologist Felix Riede at the University of Aarhus. Also, the cognitive sciences are highly interested in design and the human perception of environments, since much recent research into embodied and social cognition takes as a necessary component of thought and 'mind,' the physical body and especially the active body, with goals or purposes, in relationship to other thinking agents.[7] Such valorization of embodied and social cognition that enables both ethical and at the same time effective and efficient construction practices is all the more critically important now that AI and parametrically defined agent systems and robots are being used in design studios and on the building site, with obvious consequences for the loss of human employment, mistakes due to non-relevant software selection, machine 'glitches' or 'buggy' software, and possible unintended consequences, such as has already happened with a reported casualty from the interaction between an AI controlled robot and humans at a fabrication shop floor.[8]

Further examples are authors working in professional design and built environment research to learn from the past, include the knowledge of indigenous and traditional cultures which encompass oral and embodied/social learning, in addition to conventional, Western models of scientific discovery, such as the work of Rudofsky, Weber, Sayigh, Mileto, Van Beek, Oetelaar,

[4] See Holst's key review and introductory paper at the EAHN journal website: Holst, Jonas. 2017. The Fall of the Tektōn and The Rise of the Architect: On The Greek Origins of Architectural Craftsmanship. Architectural Histories 5(1). accessed 15. Feb., 2020. https://journal.eahn.org/articles/10.5334/ah.239/

[5] Architect can be written in Greek script as: Αρχιτέκτων. Architecture itself, its institutions and artefacts, thus have contained within its Greek root word: craftsmanship, as in αρχή = first and τέχνη = craftsmanship = architecture. See http://www.hellenicaworld.com/Greece/Architecture/en/GreekAncientArchitecture.html accessed 15. Feb., 2020

[6] See the website: https://c3net.au.dk/ their aim to - is to bring together an interdisciplinary team of researchers concerned with the human impacts of climate change and extreme environmental events in the past – as well as in the present and future. C3NET aims to create and catalyze a Palaeoenvironmental Humanities research, education and outreach cluster at Aarhus University and beyond.

[8] Asimov's Laws of Robotics are often used in AI work. https://en.wikipedia.org/wiki/Laws_of_robotics accessed 2. March, 2020

Guidoni, Benjamin and many others too numerous to mention. See the References for their research.

Furthermore, Architecture as a profession and research field has now a responsibility to engage with the humanities and sciences in efforts to advance the general understanding of and production of settlement design improvement and effects on human wellbeing. This is especially relevant since the acknowledgement by the Swiss Academy of Sciences that Architecture is its own field and indeed, operates at a 'meta-level' of enquiry, contributing to the methods, approaches and therefore findings that are possible from interdisciplinary collaboration.[9]

Therefore, the research and paper question: Shall this rupture be healed, how shall this be achieved, by whom and how will the healing of this alleged rupture be promulgated and accepted by the design and craftspersons communities, within the design, construction and art curation/art criticism sectors of the global economy?

Reformulating the designer/engineer to craftsperson relationship in the construction sector in Dana Cuff's updating of her own seminal work, *Architecture: The Story of Practice,* , which offered a then current account of architectural education and practice, in 1991, she argued for reviving "fabrication at a one-to-one scale" and "community-based design-build projects" (Cuff 2014: 92-93) in order to help in reforming and making more relevant the profession itself.. Yet, what she focuses less on in her studies of architectural practice, and very few other authors do even today, is enquiring into the role which craft and craftspeople could or should play in contemporary architectural practice and the entire value-chain of built environment delivery (known in the humanities as the *chaîne opératoire*). Her own research seems to confirm the tendency which has only grown stronger during the past two or three decades: Design, especially in the design studio, but also in the academic school, is the form of education and artistic *savoir-faire*, which makes the architects into the professionals they are. There is no need to argue about that, but what could be argued is that architecture should still safeguard its own historical and cultural tradition based on tectonic craftsmanship and so resist being reduced to a mere digital design discipline without any foothold in materiality and craftsmanship.

The lack of status and valorization of buildings and landscape sector related to skilled crafts-tradespeople still seems current today.[10] Predominant are the relationships between the key construction sector actors, designers, engineers and other related sector curators of style and design significance and the currently popular efforts and policy/funding implementation mechanisms driving the virtualization and robotization of construction, leading to a world of seamless, intangible concept to physical object construction.

Instead, we argue in favor of reformulating the profession of architecture in order to encourage and enable learning, teaching and collaboration opportunities in design schools, in design to fabrication work-flows, at construction job-sites and in other relevant fora, even at design and construction conferences, symposia and certainly in the design, design management and construction literature, certainly as members of the informant cohort or 'subject' of research, if not also co-creators.

To enable this reformulation in practice and research contexts: We propose the inclusion within the fields and disciplines of Research by Design, Design by Research, general architecture research into the architecture 'profession,' architectural history and contemporary to ancient buildings archaeology: The participation and co-

[9] See Zinnstag, Jakob, et al. 2016.

[10] The authors make this claim from over 35 years of practice in professional architectural design, design research, and research and teaching efforts in design and the humanities. See also Holst's paper, noted below and cf. Jean-Paul Morel's The Craftsman, a chapter in The Romans. 1993. Ed.: Andrea Giardina. Chicago: University of Chicago Press, or concerning modern design education curricula propositions: Fern Lerner. Foundations for Design Education: Continuing the Bauhaus Vorkurs Vision. Studies in Art Education, Issues and Research. 2005. Vol. 46, no. 3, ppg 211-226.

creation in research design, research work and the development of theories, methods and research designs: The knowledge sets, skillsets, learning/teaching regimes and the auto-didactic skills of ancient-to-historical *architektones* together with today's craftspeople. This includes current individuals that the authors propose can be seen as conceptual cognates for these roles, as in current master craftspersons that are also Architects and/or engineers/architectural engineers. These individuals still exist and are active in buildings and research production and this paper will briefly report on their work as a first step to guiding research questions and research design approaches for this reformulation of the Architecture profession and the role of agency of the persons and institutional frameworks performing in these design/construction sectors.

We further propose here, preliminary and early attempts at the formulation of research approaches, including theoretical stances, methods, research designs and concrete efforts to reformulate the relationships of the above mentioned actors toward deeper and more authentic conviviality, co-creative cooperation and collaboration.

We posit, further, that these individuals, from ancient eras and through to today, can be said to have a sort of role *identity*, in their known characteristics, activities, structures and functions in society, often within the same person and in the activities of groups of these persons acting together in teams. The difficulty in describing these persons' roles and structures/functions is itself an indication of this rupture, evidenced by the pre-Socratic use of *tektōn* and the *aristoi tektones*, where manual skill, design knowledge and creativity, ethics, sense of phronesis and awareness of artistic and societal purpose for making things were often encompassed to a greater or lesser extent based on training and experience, in one and the same person.[11]

A normative research and participatory Action Research type interventional agenda. This very preliminary proposed agenda is an interdisiciplinary effort between the author's own fields and those of their collaborators over many years, including: The experiences of architectural practice (thus both auto-ethnographic and anthropological as learning from peers and craftsperson collaborators), the humanities, including history, ancient material cultures studies, archaeology and the sociology of the professions/work, Participatory Action Research as interventions with informants toward transformation and the practices of engineering and the several sciences within the broad realm of long-term cultural adaptation to systemic natural and man-made change; popularly known currently as climate change adaptation and mitigation.

The approach should start from realizing that there are several dimensions of learning, design practice and research opportunities and knowledge spheres to take account of. We propose a 'mapping' categorizing the knowledge as dimensions as follows:

1. Cartography of knowledge of the recent history and current situation of the architect-craftsperson-engineer relationship

Dimension 1: overarching categories of knowledge to be gained: geographic regions, functions of the agents and their institutions as to how they perform which types of work and effects, structural relationships between the agents and their several institutions

Dimension 2: A diachronic view of the relationship, looking to the ancient past in several different regions and cultures and, forward to enquiring into current proposals and research on the future of the work and design relationships of making settlements and landscapes

Dimension 3: What are the different forms and sources for relevant, emic and etic knowledge about this relationship(s), i.e.: what can we induce from the data/information by studying

[11] See Holst's paper in the EAHN journal, as in note iii, in toto.

specific places and sites and their detailed histories, opposed to what can we learn from generalized knowledge of this relationship that scholars have induced from informants or deduced from theory

Dimension 4: What are the interesting and relevant forms of knowledge that can be thereby deduced from these empirical examples or from thinking through thought experiments and from theories in the humanities, architecture, and other scholarship, i.e.: the forms and content of the nomothetic and idiographic knowledges, or respectively the learnings about this relationship that can lead to generalizable, more or less reproducible and broadly accepted in peer communities knowledge for use in across different cultures and in different economic sectors, as opposed to what relevant findings can we learn about particular places, occasions, buildings and their specific histories, or their long-term taphonomy

Dimension 5: What is the market pushing the built environment sector to change toward, in terms of funding agendas, policy statements and implementation regimes, educational curricula and funding mechanisms for designer education and vocational training

Dimension 6: What directions are the broadly defined construction sector pulling the designer-craftsperson relationship to do, to remain the same, to change and toward what change, as the sector itself does its own reflection and self-critique, such as the several reports of the U.K. based Royal Institute of Chartered Surveyors, building quality assessments of the Building Research Establishment Constructing Excellence platform[12] the U.S. based National Institute of Building Sciences, and many other platforms and institutes calling for and guiding change because of measured and perceived deficiencies in the design delivery mechanisms and the built products of the construction sector.

Dimension 7: Above the known unknowns. This dimension should enquire into the unknown knowns, i.e. what we do not yet know that we know, such as can be accessed through the study of ancient histories of construction and architecture; and the unknown unknowns, such as what we might discover in both looking to the past and through experiments that seek novel solutions to new construction or the conservation of the existing stock/ historic buildings and landscapes

2. Normative research and intervention proposals for devising effective and ethical applied scholarship and virtuous transformation processes for the relationship between craftspersons and designers in the broadly defined construction sector (buildings, settlement related infrastructures, etc)

Dimension 1: Engage with current craftsperson-designer cooperation initiatives to develop and record, (.i.e. ethnographic, auto-ethnographic, knowledge management and sustainable innovation methods) scholarly research and participatory Action Research methods, their current and ongoing production of findings and interpretive results - quantitative and qualitative type of knowledge and practices and both explicit reportable knowledge and tacit, embodied, social cognition types of knowledge otherwise difficult to record via conventional means

Dimension 2: Compare, contrast and critique these knowledges and practices from Dimension 1 with the published records and scholarly or design research, from ancient cultures, through historical periods through to the current era to further a triangulation of knowledge, findings and interpretations, which should furthermore

Dimension 3: based on these findings and network engagement from Dimensions 1 and 2, develop preliminary proposals, for programs to renew, repair and help in the ongoing maintenance of the craftsperson

[12] See their reports and guidances at http://constructingexcellence.org.uk/about/

– to -designer relationship, starting with a focus on projects in the realm of the built cultural heritage (both buildings and ancient-to-recent era infrastructures). The research and interventional proposals should be devised and implemented with craftspersons and designers as co-equal co-creators, in as much as possible convivial and authentically collaborative relationships.

Dimension 4: Seek new funding and engage with currently funded projects in the above programs to promote these programs' work and to devise and produce new works. Such work should include: media productions such as documentary films, audio recordings, or other media, devising, buidling and producing onsite or travelling exhibitions that explicate this research and these practices and building and conservation projects where the collaborative work relationships between the members of the CPTs/DPTs is explicitly framed as the cooperation of co-equal and co-creative partners.[13]

The current state the design/construction relationships.

There is reported in the general construction industry journals and the popular press, in addition to architectural and engineering journals, several different types and levels of change, because of a general, measured and perceived lack of both quality in the built product and a lack of cooperation, from the design studio to the building site. (Sayigh, 2019, in toto; Rahman, 2014, in toto; and RICS et al 2018, in toto). Thus, what efforts to date that the construction industry has devised and implemented have had at most marginal success but certainly has produced a great deal of learning about the possible patways for leading virtuous change, producing better quality buildings and infrastructure and helping to enable more convivial construction work sites, that are simply non-antogonistic, but rather authentically collaborative and cooperative.

The authors propose one of the viable pathways to enable better job-site work relationships and product delivery should include this reformulation of the designer to craftsperson relationship.

Two examples of interventions in the building industry-design sphere are:

1. Haus der Farbe: An NGO in Zurich Switzerland that provides a workshop space and curriculum for designers and craftspersons to work together on specific projects, such as learning about and making higher quality building finishes and color coding for buildings in Switzerland. Their color map of all the buildings in the city of Zurich was produced by human sense agents, not computers, as they found humans to be more accurate and quicker than machines.
2. The Norwegian National Cultural Heritage Conservation Academy: A second example is the work of the NNCH Conservation Academy in Norway, along with the allied Norwegian Institut for Kulturminneforskning. They have over many years produced cutting edge research and products, including restored wooden, 900 year old barns, the restoration of 800-900 year old stave churches, and modern replicas of high grade near-steel iron axes that are apparently better at cutting and shaping wood than currently market-available stainless steel axes. This is based on the research work of several metallurgists at the NTNU University and Architect Anders Haslestad at the NNCH.

The above two examples are just two of many found even in the Nordic countries. Many other examples can be found throughout Europe and to be sure, further afield in Africa, Asia, North America and the Russian/Slavic speaking worlds. The authors look forward to working with the participants of the conference to build and maintain effective networks across many cultures and territories to repair and rejuvenate this relationship.

PAPER #7.09

PLATFORM, CONTAINER, ENVIRONMENT. 2019 SHENZHEN BIENNALE AS INNOVATION IN PRACTICE

Edoardo Bruno[a], Valeria Federighi[a], Camilla Forina[a], Monica Naso[a], Michele Bonino[a]
[a] China Room, Politecnico di Torino, Turin, Italy

ABSTRACT

In a time of supra-national economic, political and social crises, the architectural profession is acknowledged as necessitating of a fundamental restructuring in order to gain both renewed relevance as a discipline (Awan, Schneider and Till 2009; Till 2014, 9-11) and sustainability as day-to-day practice (Deamer and Bernstein 2010; Deamer 2015; etc.). A tendency to diversify the products of architectural practice - i.e. beyond buildings - is facilitated by a constantly increasing number of curatorial outlets - i.e. Triennales, Biennales - allowing to increase the perceived pace of innovation (Papastergiadis and Martin 2011, 45–62).
The paper looks at the curatorial process of the 2019 Shenzhen Biennale of Architecture and Urbanism[1] as a way to access a select sample of internationally mobile contemporary practices whose work is produced at the intersection between profession, academia, and independent research. Drawing on literature pertaining to the concept of communities of practice (Amin and Roberts 2008, 353-369; Faulconbridge 2010, 2842–2858), ethnography of practice (Yaneva 2009) and feminist theory (Frichot and Runting 2015, 397-411), we question the agency of the Biennale and similar curated events as facilitating environments entailing the reconceptualization of design practice (O' Neill & Wilson 2015; Szacka 2019). In order to do so, we look at the practices that populate the exhibition, how they self-represent and how they employ the exhibition to maximize the possibility of producing innovation.
Finally, we select a small number of installations that appear the most resilient to contingencies, and analyze their trajectories outside of the Biennale in order to understand the way specific networks are built and effects are achieved, within platforms that are indeed part of day-to-day practice, rather than existing outside of it.

KEYWORDS

Innovation; practice; Biennale; container technology; contingency.

1. THE AGENCY OF PRACTICE AND THE ROLE OF EXHIBITIONS

In a time of supra-national economic, political and social crises, the architectural profession is acknowledged as necessitating of a fundamental restructuring in order to gain both renewed relevance as a discipline (Awan, Schneider and Till 2011; Till 2014) and sustainability as day-to-day practice (Deamer and Bernstein 2010; Deamer 2015). A tendency to diversify the products of architectural practice - i.e. beyond buildings - is facilitated by a constantly increasing number of curatorial outlets - i.e. Triennales, Biennales - allowing to increase the perceived pace of innovation (Papastergiadis and Martin 2011). Cultural events par *excellence*, biennials are generally studied and debated as a global phenomenon, as tools of marketing strategies adopted by cities that strive to emerge in the neoliberal system of the so-called "knowledge

[1] More specifically, we consider the practices that applied to the Open Call of the "Eyes of the City" section and were selected for the exhibition.

economy." Even though they are inextricably associated with notions of homogenization, commodification and spectacularization of contemporary cultural experiences (Urry 1995; Evans 2003; Hornstein 2011), nevertheless these exhibitionary formats are commonly considered among the best-rehearsed media of dissemination and display of disciplinary knowledge in the fields of architecture and arts (Jones 2016; Smith 2012; Vogel 2010; Martini and Martini 2011; Gardner and Green 2016).

A growing amount of literature attempts to understand the role that such outlets have had in the development of architectural discourse ever since the onset of architecture as a liberal profession through the Beaux Arts, the Modern and the Postmodern (Macleod, Hourston Hanks and Hale 2012; Szacka 2019), to name just a few key moments in which the close relationship between curatorship and practice has allowed for a stronger perception of the architect as public figure. More recently, architecture as a practice has known a decrease in public relevance; disciplinary discourse tends to mirror a growing concern with the real agency of design with respect to pressing matters of the contemporary world such as urban poverty and informality, climate change, and even the very conditions within which design and construction are carried out as practice (WBYA 2018, Deamer 2015, Brenner 2015), while architectural education is showing an "undisciplined" move towards the scale of the city (Cuff 2014) in search of renewed relevance. If we accept that exhibitions are facilitating environments entailing the reconfiguration of design practice (O' Neill and Wilson 2015; Szacka 2019), thus impacting the way that design is understood and the degree to which it can claim relevance, we must understand how exhibitions are made as a real practice. In his conceptualization, architecture historian Florian Kossak (2012, 214) uses the term "productive exhibition" to acknowledge the exhibitionary format acting as the testing ground for "new forms of the production of architecture itself" and as "a continuation and integral part of the architectural praxis [..] that has a transformative and progressive role in the development of architecture": this allows for a re-consideration of the exhibitionary format in terms of potential agency outside the "white cube" conceptual space and its well-rehearsed politics of display, as investigated today by a growing bulk of curators and scholars.[2]

The discourse around the way exhibitions impact on architectural debate most usually revolves around an epistemological approach, centering on the distance between curators' intention and effect at a critical level (O' Neill and Wilson 2015), on the way mediated messages convey a real shift in the way architectural design is practiced (MacLeod, Hourston Hanks and Hale 2012), or on the way exhibitions allow for a stronger vector of change (Pestellini Laparelli 2018, 22) and internationalization of discourse (Filipovic, van Hal and Øvstebø 2010). These perspectives rarely allow for an unpacking of the relationship between the exhibition and the real conditions within which it is produced. Drawing on Bruno Latour's understanding of the "entanglement" (1988, 1996, 2007) and subsequent ANT explorations of the relationship between sites of reality and the production of any (necessarily sociotechnical) advancement, we set out to explode the real conditions of production of a specific exhibition, in the hypothesis that such real conditions – the contingent here and now - have a stronger impact on the content of the exhibit and therefore on the way it, in turn, impacts on discourse, than has been recognized. In this perspective, the observation of UABB 2019 – Shenzhen Bi-City Biennale of Urbanism and Architecture (hereafter UABB) is employed as a way to measure the effectiveness of the notion of "entanglement" as applied to the life-scale laboratory environment of the curated

[2] Recently, an entire issue of the magazine Volume has been dedicated to the investigation of the potentials and of the roles of biennials today (See Volume #54.On Biennials).

exhibition, looking in particular to one of the two main sections of the exhibition, "Eyes of the City.

2. OUTER TRAJECTORIES

In this section, we look at the way selected practices describe themselves as participants to contemporary discourse around the redefinition of the boundaries of architectural practice, in order to assess the role that UABB has played in their innovation/deviation/reinvention/development. To do so, we employ as main sources: 1) the data on all participants that we have gathered throughout the curatorial process, 2) parallel interviews we have conducted with nine participating groups, and 3) personal exchanges and conversations held throughout the development of the work. Collected data (1) refers to the type of firms that have participated and the way they describe their practice; on various occasions, the curatorial team were asked by UABB and local authorities to give exhaustive accounts of all participants to the exhibition, in terms of individual affiliations, geographical locations as well as narratives. The nine parallel interviews (2) were structured in three main parts: the first looked in closer detail to the structure of the group, the second to its reasons for participating to the biennale and the third to the way that each proposal has evolved within it. Both (1) and (3) were collected throughout the six months of continuous interaction with participating groups, while (2) were carried out after the opening of the exhibition. Using these data on an epistemological level allows us to define some of the strategies that are consciously deployed by these practices in order to actively push perceived boundaries of the discipline and gain agency within the contemporary world.

Within the total amount of 130 teams that applied to the Eyes of the City UABB Open Call, 25 defined their structure as "research group" or "academic association". Of the remaining 105, a large part defined its activity as "freelance" or "private studio", while 17 preferred more hybrid definitions such as

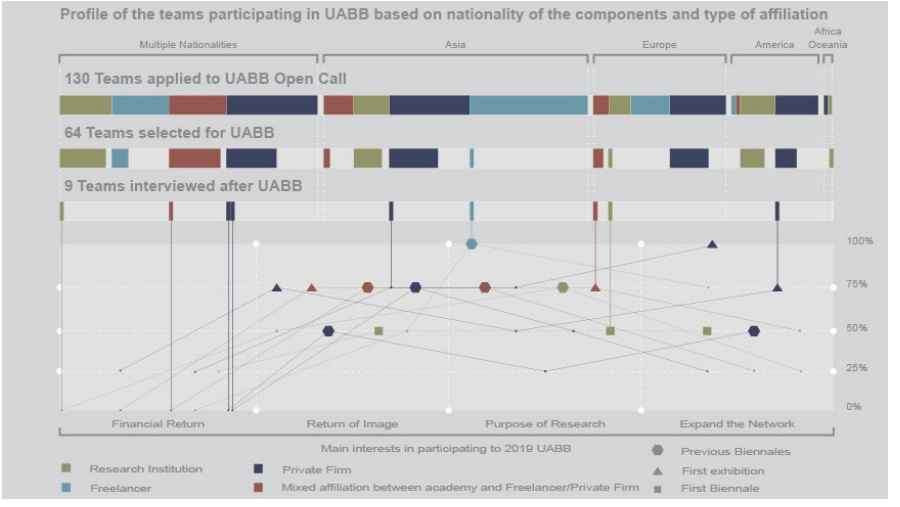

Figure 1. Tracing of the nationalities of the teams and their interests in participating within 2019 UABB – Bi-city Biennale of Urbanism/Architecture. Diagram by the authors.

"freelancer/academic", "studio/academic". Looking at the individual biographies provided by the 64 teams selected to participate, it is evident how the profile of architectural or design firm is perceived as constraining; most exhibitors show a tendency to describe their design work as other from a projection of built artifacts, towards more experimental and less tangible contents, which identify the social, interpretative and innovative role of the profession in an heterogeneous mix of multiple activities. This is
evident in the self definitions that have been provided, such as "research and media practice," "multidisciplinary design practice," "Space Lab," "platform".

While only 19% of participating groups stated an official affiliation, as group, to an academic institution, for a further 15% different affiliations explicitly coexisted as some members stated a professional affiliation to an office or private organization, while others stated an academic affiliation. Furthermore, of the 25 academic institutions involved within the UABB exhibition, 6 of them[3] participated with two or three different proposals. Some of the professional skills that were featured within participating groups were conventional ones such as architects, designer, artists and urban planners, but also extra-disciplinary ones such as "CG Artist," "Coder," "Computer Scientist," "Virtual Reality Specialist," "Software Engineer," "Aerospace Engineer," "Economic Geographer," "Actress," "Filmmaker," "Information Designer" and "Computational Designer," among others.[4] From a geographical point of view, of all participating teams, 45 have members with different nationalities, and 13 have members that currently reside and work in different cities or nations[5] .Finally, of the 64 participating groups, at least 9 were formed specifically to participate to the exhibition, across individuals and pre-existing groups.

While this sample is not wide enough to give an exhaustive restitution of the type of practices that populate architecture biennales, it is nonetheless clear that these practices, specifically, tend to structure themselves through recombinative strategies and "intercohesion" (Stark and Balàzs 2010). Contact across different cohesive groups through spatial proximity (Amin and Roberts 2008) and global mobility (Faulconbridge 2010) has been identified as the locus of innovation production; some authors argue that in order to maximize innovative potential, groups should foster "cohesion" and "connectivity" (Watts 1999; Moody and White 2003; Uzzi and Spiro 2005) as well as "closure" and "brokerage" (Burt 2005; Baum, McEvily and Rowley 2007). Building on these positions, more recently authors have proposed that communities of practice allowing for individuals to work "across" different groups show an increase in innovative activities, where "creative tensions of familiarity and diversity" are meant to "promote group performance" (Stark and Balàzs 2010, 1152).

This perspective is interesting to the degree to which the participation to a specific exhibition is not likely to be the main activity of any organised body at any time - if not in the very short term of impelling deadlines. In fact, just two of the nine interviewed groups had only low expectations of financial return, none of them had any expectation of building ties with possible clients, while they all had expectations of building ties with media, institutions and peers. Four out of nine had already participated in an international exhibition, seven out of nine had already participated in an exhibition, and all nine intend to participate in an international biennale in the future. Furthermore, nine out of nine had already been in contact with 1 to 15 other participants through a collaborative project (1), a previous exhibition (3) or a common

[4] These definitions were provided by exhibitors in the bios they submitted for the initial application and later for cultural censorship and for the catalogue publication.
[5] These data were collected by the curatorial team during the curatorial process through direct interactions with the participants, and were shown in the exhibition in the form of infographics.

network (5). In this sense, while it is clear that the construction and strengthening of weak ties (Granovetter 1973) through contact and visibility is one of the main objectives for all participants, it can also be argued that participants consciously used the exhibition as a strategy to maximize "overlappings" (Stark and Balàzs 2010) at different levels within and across communities of practice. This works at the level of organisational structures and has a direct impact on the modes of production of the project. The theme proposed by the exhibition was "partially" (6) or completely (3) in line with the team's research and work topics; significantly, in the former case, the project was a new proposal developed specifically for the exhibition, while in the latter it was an iteration of a previous project, and six of the nine groups intend to repurpose the same project for participation to another exhibition.

If we look at built installations within the exhibition as units of observation, it is clear that each installation cannot be analysed as the material effect of an abstract design idea, but needs to be read as product of an iterative process that is the result of the encounter between intercohesive practices, strategically employing the space of the exhibition as breeding ground for multiple levels of innovation, and an institutional container - UABB - in which projects go through successive rounds of modifications as the effect of a wide range of stimuli and irruptions. In this sense, UABB works as a "container" (Frichot and Runtig 2015), fostering the gradual progression of projects from world of ideas to specific, on-the-ground conditions. In the following paragraphs we look at UABB as a container for the 64 installations through a linear account of the process, and then more qualitatively at the nine installations authored by the nine groups we have interviewed.

3. CONTAINER/CONTAINED

Throughout its eight editions, since its inception in 2005, UABB has been acknowledged as one among the eleven most relevant architecture biennials worldwide.[6] Its strong impact on international discourse[7] is mainly due to its approach, the exhibition aspiring to act as a "catalyst"[8] and as a laboratory for urban transformation. UABB declares ambitions that are not limited to the display of the "state of the art" of global architectural debates: rather, the event aims at establishing a proactive transformative tension towards the issues related to hyper-urbanization processes within and around the local context of Pearl River Delta mega-region. There is a growing narrative around UABB's unconventional approach as well as the innovative charge of practices that participate in it. Despite this, UABB (as a direct emanation of the Shenzhen Urban Planning Bureau) operates within a municipal-level political scenario bound to a strong regulatory framework. As a consequence, it is necessary to take immediate distance from a narrative of epistemological correspondence between intentions and effects. Rather than linear and one-directional, the trajectory between project and built object is iterative and recursive, made of twists and turns, of constant exchanges and negotiations, as much as any work of architecture (Armando and Durbiano 2017).

In this paragraph, we look at the mechanisms of the exhibitionary institution, and at the actions that have been carried out within it by a collective of actors. In our working hypothesis, the exhibition acts as a "container" of practices: this section aims therefore at briefly unfolding the commonly intended image of the exhibition as a monolithic institution where the process involving curation as a real practice is often concealed, focusing instead

[7] The 2017 edition of Shenzhen-Hong Kong UABB has been visited by more than 550.000 people (Source: UABB Organizing Committee. See also Volume #54 "On Biennials"). Recently, UABB has been defined by online platform Archdaily as the "The World's Most Visited Architecture Biennale" https://www.archdaily.com/930683/the-worlds-most-visited-architecture-biennale-opens-in-shenzhen?ad_source=search&ad_medium=search_result_all. Accessed 2020.02.10

[8] The term "catalyst" is commonly used by the official narrative of the event to describe the curatorial approach of UABB.

on measuring the exchanges that took place between the container and embedded practices, with the purpose of demonstrating their negotiating and incremental nature.

Our hypothesis is that there are measurable points in the collision between the ontological level of exchanges and the epistemological level of each narrated agency, and that those can be found in the progressive validation of the latter within the former.

These validations take the form of signed contracts and documents, defining how the implementation of the project has been developed. This aspect is not secondary if we want to overcome the perception of the exhibition container as simple platform, and go beyond the threshold dictated by the exhibition's communicative media to understand the mechanisms through which the exhibition works.

If each agreement remains unchanged between the parties until a new agreement is reached, as successive synchronic objects, proposals are, on the contrary, diachronic objects. In different moments of development, proposals undergo modifications prompted by exchanges with the institution that legitimizes their eventual translation into built objects. In this sense, we represent proposals as trajectories: in the exhibitors' initial intentions these would proceed linearly from acceptance to construction, but, due to

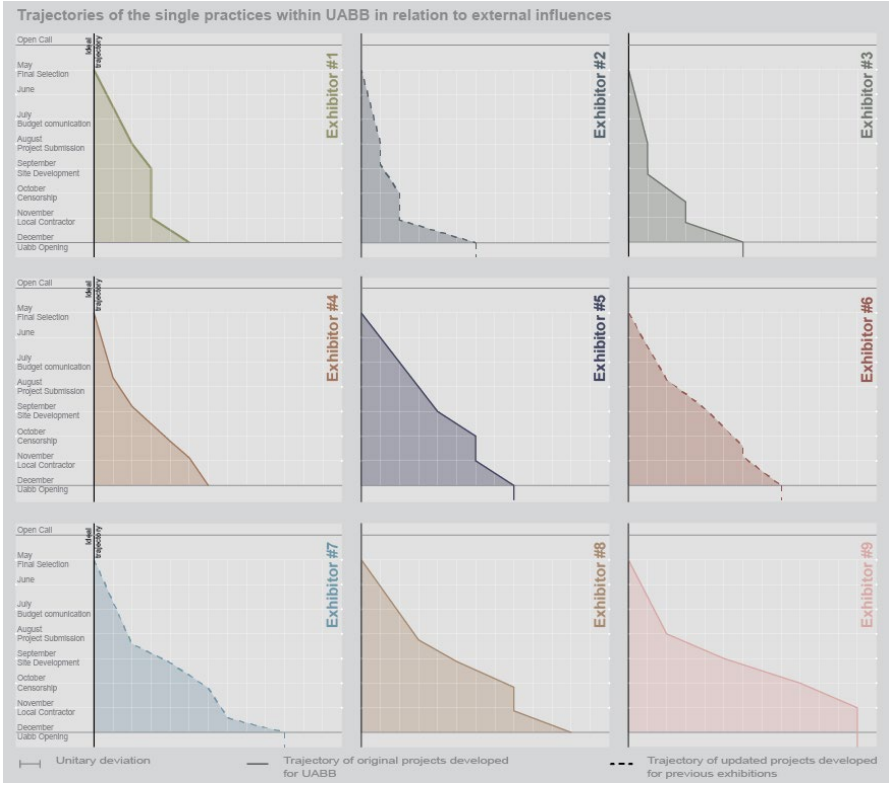

Figure 2. Tracing of the trajectories of the practices of each interviewed teams within 2019 UABB – Bi-city Biennale of Urbanism/Architecture. Diagram by the authors.

the many irruptions of the container-biennale in its many forms, they need to deviate to get to the final stage of construction.
Under this perspective, the process works as continuous exchange; each modification is neither a result of authorial intentions, nor an automatism of cause and effect, or action and reaction. Since it is capable of internalizing an enlarged vision, and carry the agency of a validating collective, we can look at it as a socio-technical and incremental process.
Also because there are no clearly stated rules that can be accepted by all parties from the start, acceptance proposals are not either accepted as-is or excluded, but are rather co-constructed through a more synergistic process, where the agency of one party overlap with the agency of the other.
This exchange was analyzed using the data derived from the parallel interviews carried out with 9 of the participant groups: these were asked to evaluate the impact of some irruptions on their proposal. Exhibitors were asked to evaluate, on a scale from 1 to 5, how much the proposal had been modified as a response to each of the following irruptions: specific budget allocation changes, contents revisions, site development, local producers requests, submissions deadlines; which, at different times along the process, influenced the proposals to varying degrees. The diagrams allow to visualize the results of the interviews and compare them (fig. 2). From these, two aspects emerge as immediate demonstrations of our hypothesis: first, that practices are not developed independently from the container, and second, that the irruptions have different impacts at different moments, depending on the specific proposal.
The first aspect points to the fact that practices consciously adapted to embed within the container. No line of the diagram is perfectly vertical; that is, no practice went through the container without having to negotiate at least some aspects of their proposal. This appeared as the only means to survive, in a continuous tension between container and contained and their opposite agencies - on the one side, the procedural and bureaucratic eagerness to get things done, on the other the need to maintain the integrity of a design intention while striving to obtain the former's legitimation.
The second aspect makes explicit that there is no generalizable relationship of causality between each irruption and its effects on proposals, as effects change from one proposal to the other and from time to time. The spatialization of this gap is a non-constant deviation between irruptions and practices' intentions. By looking at the diagrams, it can be observed that exhibitors #1, # 2 and # 3 (fig. 2.1, 2.2, 2.3) described their initial proposal as remaining more or less unchanged until it had to face site development and local contractors' feedback on feasibility. Of these three teams, two are research institutions whose proposal was the result of previously developed research work, while the third one is a renowned architecture firm. Two of them had already participated in a biennale before, and many of their components are from China. These groups likely had a clear idea from the start of the project they wanted to show in terms of conceptual narrative, and concentrated their efforts in reworking it strictly when needed, in answer to the formal requests of construction and set-up.
At the opposite end of the spectrum, exhibitors # 4, # 5 and # 6 (fig. 2.4, 2.5, 2.6) described their proposal as having consistently changed in the first phase of concept development, while being easily translated into part of the exhibition in the production phase. In this sense, their initial redefinition was deemed useful to make these proposals more resilient to formal adjustments. All these teams are small to mid-size private offices with a strong research agenda, and had previously participated in other minor exhibitions. This shows how some proposals may be innovative in their capability in discovering how containers work step by step, strengthening their perspective at each negotiated stage.

Finally, exhibitors # 7, # 8 and # 9 (fig. 2.7, 2.8, 2.9) show a definite diagonal trajectory, telling a story of constant negotiation throughout the process. These three teams had previously participated in a biennale, and defined themselves as experimental practices. Their proposals were described as having undergone the most changes, both in the initial phase of conceptual development and in the phase of development and construction. In this sense, these are the practices that have demonstrated the most willingness to adapt to contingent factors and, more generally, to the container.

These three categories are intended to define a spectrum of the possible strategies that practices employ in order to legitimize their work within an institutionalized container. To trace the complex tangle of relationships that are in place allows to redefine the narrative of an exhibition, past the interpretation of each object as a result of a curatorial intention.

4. CLOSING REMARKS

By tracing the variable trajectories of proposals, we attempt to describe how selected practices constructed their progressive legitimation and, therefore, the feasibility of their proposals, through strong conceptualizations, constructive detailing or minute negotiations.

The graphs demonstrate that there is a continuous interchange between the space of ideas and construction: within the container, the two poles converge and diverge continuously.

The irruptions of final selection, blueprints submission, cultural censorship, all had effects on the level of the symbolic values of the proposals, supporting the vision and authorial perspective of each exhibitor. Budget communication, site development, and meeting with the local contractors had effects mainly on the translation of projected symbols into physical matter. Their turnover along the route depends on the rules of the container as well as on the contingencies that can co-exist with those rules.

A description of exchanges allows the observer to define categories based on the different degrees of interaction, with the purpose of deconstructing the narrative of the "white box" toward an operative definition of "productive exhibition".

There have been proposals capable of holding firmly to their contents and having to change only to the test of reality. Others have experienced the opposite while still others have had to incrementally stake the entire proposal to be able to legitimize themselves inside the container. Under this perspective institutionalized containers should be read as negotiated spaces rather than platforms. Narratives on exhibitions focus on communicative and epistemological stances, while this paper aimed at observing how the development of projects engenders symbiotic exchanges between practices and containers. Mapping how practices deploy strategies to spatialize their ideas opens the possibility to shift scholarly attention from synchronic media objects to the diachronic procedures through which they are produced. The preliminary categorization shown in this paper is intended to point towards a possibility of measuring the relationship between the symbolic and the material, to explore practices and define the circumstances within which they work.

PAPER #7.10

GLOCAL ARCHITECTURE AGAINST CLIMATE CHANGE: RICE STRAW IN VALENCIA

A. Quintana[a], Joan Romero[b], I. Guillén-Guillamón[a], F. A. Mendiguchia[a]
[a] Center for Physics Technologies, Polytechnic University of Valencia, Valencia, Spain
[b] Instituto Valenciano de la Edificación, Valencia, Spain

ABSTRACT

Global warming is today a reality, and some countries are already suffering its consequences. The building industry is one of the main contributors to this effect, being responsible for around 23% of the carbon dioxide worldwide emissions. Despite this being a global problem, the already available solutions are mostly local. To tackle this situation, each country or community needs to maximize the possibilities its local resources offer sustainably. This way of thinking globally about local solutions is called glocal. This paper tries to exemplify this concept with the case of the rice fields located in the Albufera park in Valencia. After the harvest, there is a vast amount of straw that remains over the rice fields. This rice straw is typically considered a residue and ends up either burned or mixed with the soil. These management practices not only generate a considerable amount of CO_2 and CH_4 but also represent a threat to the local population and the integrity of the flora and fauna of the natural park. One possibility for avoiding the mentioned impacts is to use the straw as a raw material. This study analyzes the environmental benefits and the acoustic characteristics of prefabricated building panels containing rice straw as the primary element for building façades. The environmental results show that using the straw panels not only reduces the carbon dioxide emissions but also avoids the emissions related to the straw management practices. When it comes to the acoustic insulation, the results obtained are comparable to most common façade typologies in the Spanish construction sector.

KEYWORDS

Glocal architecture; climate change; LCA; carbon emissions; building acoustics.

INTRODUCTION

Climate change has become a priority in all aspects of human life. Since the first climate emergency declaration (Ripple, Wolf, Newsome, Barnard, & Moomaw, 2019), 25 countries and more than 1250 local governments have released their own. The effects of climate change are starting to be noticeable worldwide, and they are already causing severe damage in some impoverished countries (Climate Centre, 2018). This is just the beginning of a process that is only going to accelerate unless international measures are taken immediately. Considering the severity of the situation, industries must adapt and find ways to carry their activities without compromising present and future generations. The building sector has shown to be especially reluctant to change. Despite the relatively high amount of new materials with a low environmental impact, most new buildings tend to use conventional high-impacting options. This is the case of concrete, responsible for a large amount of the total carbon emissions in the world, as well as metal structures, glass, bricks, and many others.

Since buildings are designed to last for decades, both construction companies and costumers lean toward materials and building typologies with a proven record of reliability. There is only one solution to counteract that tendency: to prove that the new alternatives and biological products are better for the environment than the conventional options and perfectly adequate for the building sector. In many cases, bio-based building materials have better thermal properties and are healthier for the dwellers.

Materials used on a global scale like concrete or metal are not compatible with a sustainable future. The extraction of the raw materials and the processing required during the manufacturing process generates an immense amount of waste and carbon emissions. Many innovative solutions are made from biological materials. Each country or even region has a different environment with different crops and different local conditions. That is why the availability of biological raw materials changes geographically. Each region should try to find raw materials extracted in its surroundings to minimize the emissions associated with transportation. Focusing on a local scale to tackle both global and regional problems is called Glocal. This concept was coined by Akio Morita in the 1980s (Dr. Pradip Kumar Das, Mr. Pema Lama, & Tamang, 2019). Since then, it has been used for developing business models in international companies, but it has barely had any repercussions in the architecture sector. This concept could be applied in architecture to counteract the growing homogeneity both in design and in construction materials used worldwide.

Valencia, a city located on the Spanish Mediterranean coast, is well-known for the use of rice in its local cuisine. The rice used to meet the demand is mostly farmed in the southern part of the city, in an area surrounding a coastal lagoon called Albufera. The Albufera natural park, formed by the coastal lagoon and its surroundings, is considered a symbol of the local identity. Rice cultivation is an important economic activity for the city and a source of pride for its inhabitants. However, the impact over the environment this activity generates has been controversial for several decades and continues to be an unsolved problem nowadays. The conflict originates from the vast quantity of straw remaining over the fields after the harvest. In just a few weeks, the rice fields in Valencia generate between 75000 to 90000 tons of rice straw. Properly managing this quantity of straw requires an amount of machinery and workforce that the farmers are not able to afford. Because of that, straw has traditionally been burned over the fields. This practice generates not only CO2 but also NOx and Sox. As a way to avoid those impacts, the Common Agricultural Policy forced the farmers to mix the straw with the soil as a fertilizer. Although this practice might seem better, it generates an enormous quantity of CH4 due to the anaerobic decomposition of the straw. Taking everything into consideration, the only way to avoid those emissions is by turning that waste into raw material.

Using a wooden frame and compressing the straw, it is possible to create straw panels. This idea was pioneered by the company Okambuva Figure 1. This study will compare the carbon footprint and the acoustic insulation of the rice straw panel with a conventional façade typology

Figure 1. Construction process using rice straw panels.

1. GOAL

The goal of this study is to analyze the potential environmental benefits of using rice straw panels as the building façade instead of other conventional constructions. Additionally, the study assesses its airborne acoustic insulation.

− To compare the carbon emissions generated by a square meter of straw façade with a typical double-layer brick façade. The software used to create the inventory and perform the calculation is Simapro

− To analyze the influence the management of the straw has over the total impacts of a square meter of façade.

− To obtain the acoustic insulation offered by the rice straw panels and to assess if it meets the required building standards.

− To exemplify how using regional biological materials can be a way of both mitigating climate change and preserving local environments

2. METHODOLOGY

This study is structured around the comparison between rice straw panels and a double layer brick wall typology, common in the Spanish construction market. The work can be divided into two separate phases:

− Life cycle assessment: The first phase consists of performing a life cycle assessment from cradle to gate of the rice straw panels and comparing it to a conventional two-layered brick façade. The calculations and life cycle inventory are carried out using Simapro. Simapro is a software that uses reliable databases to account for all the environmental impacts generated by any human activity.

− Airborne acoustic insulation measurement: This part consists of measuring the acoustic insulation of the typologies under study in the acoustic transmission chamber. The transmission chamber consists of two rooms, an emitting room, and a receiving room, separated by the construction that is going to be tested. Pink noise is emitted from a loudspeaker in the emitting room. The sound pressure level of the pink noise is measured in both rooms to determine the acoustic pressure attenuated by the wall. The methodology follows the process described in the ISO 717-1 standard (ISO, 2013)

2.1. Typologies under study

As explained in previous sections, the main typology under study is a kind of prefabricated panel composed mainly of rice straw. The straw is compressed and held together using a wooden frame. The standard panel is designed for low rise buildings, but its wooden frame can be adapted to bear loads

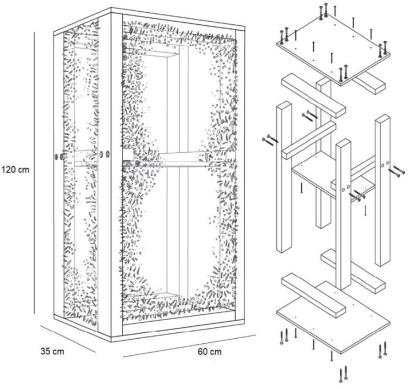

Figure 2. Straw panel dimensions and frame design SOURCE:("Okambuva," n.d.)

Material	Mass (kg)
Rice Straw	49
Clay mortar	100
Lime mortar	31.5
Pine wood	7

of higher constructions. Therefore, the structural integrity of the panel depends on the wood frame, while the compressed straw provides thermal and acoustic insulation, besides some extra rigidity. The physical characteristics of the panel are depicted in Figure 2, and the material inventory is detailed in Table 1. By covering the panels with lime mortar, the straw core and the wood frame are protected against the weather conditions, fungus, xylophagous, and other kinds of insects (Elert, Rodriguez-Navarro, Pardo, Hansen, & Cazalla, 2002).

The other typology used for the comparative study is a double layer brick wall Figure 3. This wall type is described in the Spanish Technical Building Code in its catalog of building elements (Ministerio de Fomento, 2011). The inventory of the façade is specified in Table 2.

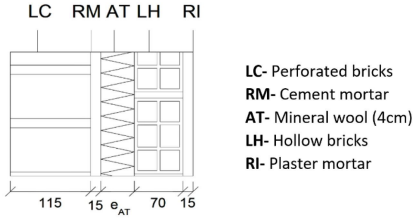

Figure 3. Double layer brick façade.

Material	Mass (kg)
Perforated brick	83.63
Hollow brick	53.33
Cement mortar	90.7
Mineral wool	5
Gypsum mortar	18

Table 2. Inventory for 1 m2 of Façade 1

3. CARBON FOOTPRINT. LIFE CYCLE ASSESSMENT

3.1. Scope definition

This study will analyze the life cycle of the straw panels from cradle to gate. All the impacts related to the building process, maintenance, and end-of-life will not be considered. In this particular study, the only environmental indicator will be the global warming potential. This indicator is measured in kg of CO_2 equivalent.

3.2. Functional Unit

The functional unit used to assess the carbon footprint is 1 m^2 of wall. The life cycle inventory for the façades is summarized in Table 1 and Table 2.

3.3. Data quality

The data used for the article come from different reliable sources. The data for developing the Life Cycle Inventory of the rice straw panels comes from direct contact with the production company("Okambuva," n.d.). The carbon emissions produced during the burning process and the process of mixing the straw with the soil were obtained from the study developed by Elena Sanchis (Sanchis Jiménez, López Jiménez, & Calvet Sanz, 2014). The data needed to create the Life Cycle Inventory of the brick wall was extracted from the Ecoinvent database V3.5 (Ecoinvent, 2016). Ecoinvent is a not-for-profit organization founded by institutes of the ETH Domain and the Swiss Federal Offices. This database collects highly reliable information due to its peer-review process (Pascual-González, Guillén-Gosálbez, Mateo-Sanz, & Jiménez-Esteller, 2016).

3.4. Life cycle scenarios for the rice straw panels

The study will compare the carbon emissions that are avoided depending on the waste management practices. The different possibilities will be divided into three scenarios:

– Base case scenario (BCScenario): The influence of the management of the straw is not considered in this scenario. It accounts for the impacts generated during the recollection of the straw, the transportation, the manufacturing of the panels. The rest of the raw materials are also considered.

– Avoiding burning scenario (ABScenario): This scenario accounts for all the processes considered in the base case and subtracts the greenhouse gases produced during the burning of the straw. This scenario shows how much CO_2 equivalent could be avoided per square meter of rice straw façade used in case the straw were going to be burned.

– Avoiding mixing with the soil scenario (AMScenario): In a similar way as the previous one, this scenario considers all the impacts in the base case scenario and subtracts the greenhouse gases generated when mixing the straw with agricultural soil after the harvest. This scenario accounts for how much the emissions can be reduced by using one square meter of rice straw panel in case the straw were to be mixed the soil.

3.5. Carbon footprint results

The carbon emissions generated are depicted in Figure 4.

The results obtained, Figure 4, clearly show a big difference between the impacts generated

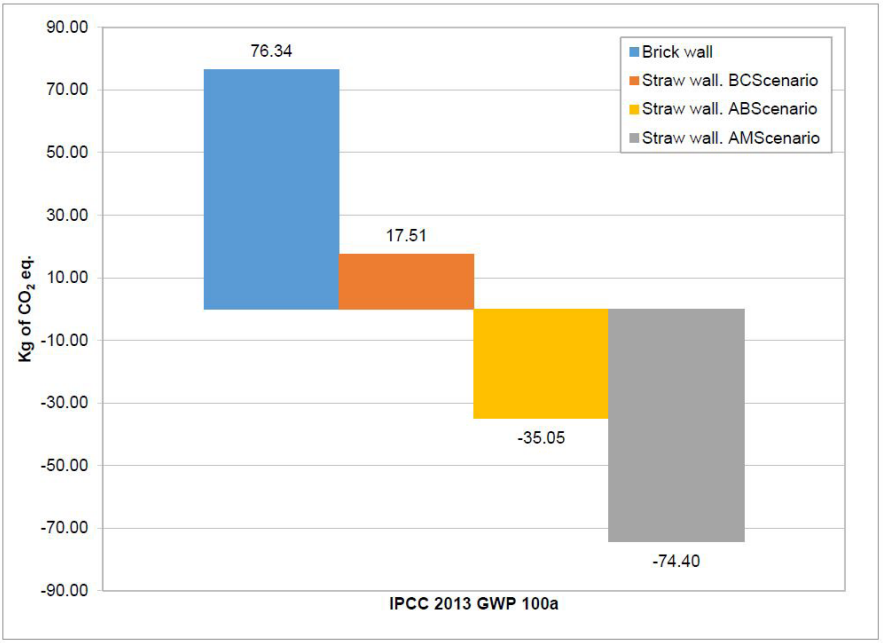

Figure 4. IPCC Global Warming Potential.

by the Brick wall and the impacts generated by each one of the three straw wall scenarios. When comparing the Brick wall to the less favorable straw wall scenario, the BCScenario, the straw wall reduces 76.3 % of the impacts generated by the brick façade. It is, therefore, safe to say that the straw wall façade reduces the impact over the environment in comparison to the brick façade studied.

The comparison between the results of the three different building façade scenarios illustrates clearly how the different management practices of the rice straw affect the environment. Looking at the ABScenario, it can be seen that by manufacturing 1 m^2 of rice straw wall and preventing the burning of the amount of straw contained in it, the emission of 35.05 kg of CO_2 equivalent is avoided. The results obtained in the AMScenario show that preventing the mixing of the straw with the soil by manufacturing straw wall panels avoids the emission of 74.4 kg of CO_2 equivalent.

4. ACOUSTIC PERFORMANCE

A straw wall has been built at the acoustic lab of the Polytechnic University of Valencia to assess the acoustic insulation of the straw wall panels. The preliminary results show that the acoustic insulation of the rice straw wall is adequate as a building façade. As said in previous sections, the acoustic measurements have been performed according to the ISO 717-1 standard (ISO, 2013). The equipment used to perform the acoustic measurements is detailed in Table 3. The comparative preliminary results of the straw wall insulation are shown in Table 4.

Device	Company	Model number	Serial number
Building acoustics analyzer	Brüel & Kjäer	4418	1086424
Spectrum analyzer	Brüel & Kjäer	2148	1701550
		7667	1819863
Microphones	Brüel & Kjäer	4416	1776748
			1776646
2 rotating microphone stands	Brüel & Kjäer	3923	1877571
			1877572
Sound source	Brüel & Kjäer	4224	1148210
Pistonphone	Brüel & Kjäer	4220	1404458

Table 3. Equipment used for the acoustic measurements

	$R_{,w}$ (C; C_{tr})
Brick wall	49 (-1, -2) dB
Rice straw wall	47 (-2, -7) dB

Table 4. Weighted sound reduction index of the typologies under study.

As can be seen in table 4, the sound reduction index Rw of the rice straw wall is 2 decibels lower than the one obtained with the brick wall. Two walls separated apart by two decibels could be considered as equivalent, regarding the fact that the human auditory system can only notice differences in sound pressure level of at least 3 decibels.

5. DISCUSSION

After obtaining the carbon footprint and the acoustic results, it is possible to consider the use of rice straw panels as an alternative to other more conventional solutions. This study has been developed to exemplify how architecture, and the building sector can take part in solving local and global problems. Manufacturing and using the rice straw panels not only avoids the emission of between 35.05 and 74.4 kg of CO2 equivalent but also tackles a very controversial local problem. As explained in the first section of this study, there is a complicated relationship between the local ecosystems, rice cultivation, and the city of Valencia. The impact the management of rice straw has in the area goes beyond the carbon emissions. The burning of the rice straw releases chemical compounds into the air that harm human health. Depending on the direction of the wind during the burning, a big cloud of smoke can cover part of the city, having an impact on the local population. In the case of mixing the straw with the soil as a fertilizer, the methane emissions generated are not the only problem either, since the rice straw fields are connected to the Albufera wetland. The incorporation of the straw has a direct effect on the coastal lagoon, producing an effect known as eutrophication. Eutrophication refers to the excessive growth of algae produced by high levels of nutrients and minerals in the water. Eutrophication is one of the most common problems in lakes, lagoons, and rivers in Spain, and it is responsible for flora, and fauna depletion (Cobelas, Olmo, & Ruiz, 1992). This effect, combined with other environmental problems threatening the Albufera natural park,
has put the local ecosystem in extreme danger(Lloret, Marín, & Marín-Guirao, 2008) (del Barrio Fernández, Gómez, Alba, Díaz, & Revilla Cortezón, 2012).
Problems such as this one affect many countries and regions all over the world. The building industry, as one of the most impacting production sectors, must take responsibility and try to help in solving, or at least mitigate those situations. Fortunately, the use of biological products not only is favorable environmentally wise but also, it usually provides good thermal insulation, which has a positive effect on the entire life cycle of buildings. Besides, using these kinds of local materials raises awareness in the general population. It is a way to get local people involved in their environment. Taking everything into consideration, designing buildings with a glocal idea is a perfect way for architecture to be part of the solution to both climate change and to many problems that affect local communities and ecosystems everywhere.

CONCLUSIONS

After the completion of this study, several conclusions can be drawn:
– Using straw panels as a building façade reduces 76.3% the environmental footprint compared to a typical double-layer brick façade
– Considering that the two likely scenarios for the rice straw are either burning or mixing with the soil, it can be stated that using the straw to build façade panels avoids the emission of carbon dioxide. When the straw is burned, manufacturing a square meter of rice straw panel avoids 35.05 kg of CO2 equivalent. If mixing the straw with the soil is the considered scenario, the straw panels avoid the emission of 74.4 kg of CO2 equivalent

per square meter. The preliminary acoustic measurements show that the rice straw panels provide adequate acoustic insulation to be used as a building façade. The acoustic insulation is comparable to the ones obtained with the other commonly used façades in the Spanish context.
– The results obtained so far indicate that building using rice straw panels as the building envelope is a perfect alternative in the Valencian context.
– Glocal architecture is the best way for the building sector to take responsibility by mitigating climate change and contributing to bring back local ecosystems to a healthy state.

ACKNOWLEDGEMENTS

This study is self-funded by the center of physics technologies of the polytechnical university of Valencia. The materials used for setting up the laboratory measurements were provided be company Okambuva.

PAPER #7.11

TRANSFERRING VISUAL METHODS FROM DESIGN TO SOCIAL SCIENCE TO ADVANCE BUILT ENVIRONMENT RESEARCH

Caryn Brause[a]
[a]University of Massachusetts Amherst, Amherst, MA, USA

ABSTRACT

Designers are well positioned to transfer visual methods from design-focused prospective sensemaking activities to qualitative social science methods in order to deepen translational research efforts. This paper contributes to the discussion regarding methods designers can employ to strengthen hypothesis building when working with qualitative data by demonstrating the use of visual tools available in Computer Assisted Qualitative Data Analysis (CAQDAS) software. The paper outlines steps in the initial analysis process for a research project investigating the relationship between collaborative professional practices and design outcomes. The pilot data were analyzed in MAXQDA to conduct thematic analysis with codes developed inductively and added to a deductive organizing framework. The Visual Tools, including MaxMaps and the Code Matrix Browser, were employed to build visualizations that identified emerging thematic relationships, and to develop and refine hypotheses. This paper argues that visual tools available in CAQDAS software position designers to build on their disciplinary expertise to more meaningfully contribute to research methods that seek to improve the built environment.

KEYWORDS

Qualitative data analysis; CAQDAS; visual tools; architecture; collaborative practice.

INTRODUCTION

There have long been calls for qualitative researchers to create more systematic and powerful displays of qualitative data (Miles and Huberman 1994). However, since many qualitative researchers are not trained in the visualization and pattern-synthesizing methods central to "designerly ways of knowing" (Cross 1982), there are few examples in the social science literature to help researchers understand how to employ the visual tools found in Computer Assisted Qualitative Data Analysis (CAQDAS) software to do so. Designers are well positioned to advance this literature by demonstrating how to transfer visual methods from design-focused prospective sensemaking activities to qualitative social science methods. This paper demonstrates the use of visual tools available in CAQDAS software by outlining steps in the initial analysis process for a research project investigating the relationship between collaborative professional practices and design outcomes. The pilot data were analyzed in MAXQDA to conduct thematic analysis with codes developed inductively and added to a deductive organizing framework. The Visual Tools, including MaxMaps and the Code Matrix Browser, were extensively employed to build visualizations which identified emerging thematic relationships, and to ultimately develop and refine hypotheses. These led to a sharpened focus on the participants' expressed drives towards quality, innovation, and experimentation in their work as well as the varied methods, strategies, and structures they exercised to

achieve these objectives. By employing visual techniques, previous assumptions about the original research questions were challenged and new refined research questions were developed for future phases of work.

1.BACKGROUND

1.1. Qualitative Social Science Methods in Built Environment Research

Many methods drawn from social science research can contribute to the exploration of essential architectural research questions. As outlined by the AIA in their 2019-2020 Research Agenda, these questions cut across individual, building, and societal scales of action. Qualitative social science methods may be particularly useful to explore architectural agendas that concern the many areas of human behavior, relationships among project agents, and understanding the role of design, community engagement, and culture to improve equity and quality of life ("AIA Research Agenda 2019 and 2020" 2019). Qualitative methods are particularly well suited to address research problems in which the variables are not well defined and when the literature does not yield sufficient information about the phenomenon of study (Creswell 2012). Because data are usually collected in naturalistic settings, qualitative methods possess many strengths for built environment inquiry, including their identification of contextual factors as they relate to the phenomenon of interest, and their responsivity to local contexts and stakeholders' needs. These aspects stand in contrast to quantitative studies, in which the researcher may miss out on important data because the focus is on theory or hypothesis testing rather than on theory or hypothesis generation (Johnson and Onwuegbuzie 2004).

1.2. Qualitative Data Collection and Analysis

Qualitative data collection methods take many forms, including interviewing, observations gathered in the field, reviewing texts, documents and records, and gathering audio visual materials and objects. These data collection strategies produce a wealth of data but not all of it may be significant to the research question. In order to identify and focus on the data that is most meaningful, qualitative researchers engage in cycles of analysis to search for patterns in the data and for concepts that explain why those patterns are present (Bernard and Ryan 2010). Miles and Huberman (1994) provide one way to visualize this process by describing qualitative data analysis as phases of data collection, data reduction, data display, and conclusion drawing and verification. (Figure 1)

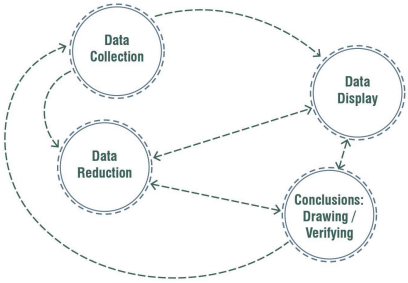

Figure 1. Components of Data Analysis.

In their systematic framework, data reduction refers to the process of "selecting, focusing, simplifying, abstracting, and transforming" raw data and occurs continuously throughout the life of any qualitatively-oriented project. It may take forms ranging from initial sampling decisions to data coding, identifying themes, and writing up project summaries. In this model, data reduction is not separate from analysis; it is a "form of analysis that sharpens, sorts, focuses, discards, and organizes data in such a way that 'final' conclusions can be drawn and verified" (Miles and Huberman

1984, 10-11). Data display, the organizing and assembling of information that permits conclusion drawing is, likewise, a central part of the analysis process. Since qualitative data often comprise large volumes of text that are hard to cognitively process, it becomes essential to find methods so that researchers can visualize the data, begin to draw conclusions, and then verify their findings.

1.3. Visual Tools in Computer Assisted Qualitative Data Analysis (CAQDAS)

Over the last forty years, Computer Assisted Qualitative Data Analysis (CAQDAS) software packages have been developed to assist with a wide range of tasks associated with taking a qualitative approach to qualitative data (Wolski 2018). These special purpose database management programs provide tools to expedite the practical aspects of qualitative research project work including content searching, linking, coding, querying, writing, annotating, mapping and networking. Silver and Lewins (2014) diagram the main overarching qualitative tasks as integrating, organizing, exploring, interpreting and interrogating data, and they outline how these tasks are supported by CAQDAS software in order to build explanations or theories, or to enlarge on a theory.

One practical aspect of this project work is creating and visualizing connections to understand and to communicate relationships, patterns, processes, and ideas as they are observed in the data (Silver and Lewins 2014). CAQDAS packages increasingly include advanced mapping or networking tools which accelerate the visualization of these connections. For projects based on deductive analytic frameworks, these tools can be used to graphically represent hypotheses or theoretical models from the project outset. For projects employing inductive, bottom-up approaches, these tools may be instrumental for generating and representing developing theories and explanations, as will be demonstrated in the Study Example.

The next section will demonstrate the use of a select group of visual analysis tools found in the CAQDAS package MAXQDA (Kuckartz 2018). In particular, the MAXMaps tools, available in the Visual Tools panel, build on Miles and Huberman's (1994) suggestion to create more systematic and powerful displays of qualitative data (Kuckartz and Rädiker 2019). While visualizations are valuable both in the analytic process and for communicating results, the Study Example focuses on data-based representations that visually represent relationships during data analysis to advance hypothesis building.

2. STUDY EXAMPLE: VOICES FROM THE FIELD

The use of QDA visual tools will be demonstrated by discussing the initial process and findings from a research project, Voices from the Field: Impact of Collaborative Practices on Design in Nordic Countries, investigating the relationship between collaborative professional practices and design outcomes. The data were analyzed in MAXQDA to conduct thematic analysis with codes developed inductively and added to a deductive organizing framework. The Visual Tools were used at regular intervals to visualize emerging thematic connections and, as the project progressed, to develop and refine hypotheses.

2.1. Research Design

The data for this project were generated as part of a constructivist interview study (Charmaz 2014). The study design aimed to capture the perspectives of participants and focuses on how these different viewpoints can contribute to an understanding of the larger phenomenon under study—the relationship between collaborative professional practices and design outcomes in the Finnish practice context. When gathering data on differing values, understandings, and experiences,

interviews are an appropriate method for gaining insight into how different participants construct meaning from their shared experiences (Kvale and Brinkmann 2008). Research questions structuring the project included: Who are the participants' most influential collaborators and how do these collaborators contribute to enhancing the quality of their work? How and why do these design professionals collaborate? What value does collaboration hold for them in achieving their design objectives? What challenges do they encounter in the collaborative process? And, in what ways does the Finnish context contribute to these phenomenon?

2.2. Data Set

Theory or concept sampling was used to identify participants for this study in order to select information-rich cases to contribute to understanding the central phenomenon under study (Patton 1990). Recruitment took place in advance of data collection through introductions to firms by an academic colleague in Finland. The four selected firms had received acclaim for their public design projects, as measured by winning significant peer reviewed public competitions and design awards. However, the selected firms are each at a different stage of development, are different sizes, and conduct work in different markets, providing a range of perspectives.
A semi-structured IRB-approved interview protocol was employed during the fieldwork (Patton 1990). Interviewees understood that the research concerned the role of collaboration in contemporary design practice and that one purpose of the visit was to understand more about their practices and the Finnish practice environment. Interviewees were sent a set of standard questions in advance, which were used as a framework for the interview combined with knowledge about their specific projects that had been researched in advance. The conversation was free-flowing; questions were not necessarily followed in a particular order though the overarching questions regarding the role of collaboration in their work and the most influential agents in these collaborations were asked of each participant.

2.3. Data Analysis

Interviews were digitally recorded, transcribed verbatim by a transcription service, and checked for accuracy during coding. The data were analyzed by importing transcripts into MAXQDA to conduct thematic analysis. Only text was coded; non-verbal interactions were excluded. The transcripts contain free-flowing text, which is delineated by turns at talk. The unit of analysis is a chunk based on an "idea unit;" chunks are coded based on where a single idea starts and ends (Kurasaki 2000).
Codes were developed inductively combined with a deductive organizing framework, which was employed to develop the start list (Bradley, Curry, and Devers 2007). The preliminary codes were drawn from existing literature, the author's previous research on this topic, and practical experience in the field. These deductive codes concern the primary agents with whom architects collaborate including other architects, consultants, clients, manufacturers, fabricators, and contractors. The initial deductive codes also included methods and strategies for realizing built work including contracts, project structures, and collaborative behaviors. Additionally, as the transcripts were analyzed, codes were created that captured themes related to the particular culture of the architecture, engineering, construction, owner (AECO) industry in Finland. These were used to highlight similarities and differences from the US context. These initial general codes were sorted according to whether they described the Finnish academic, practice, or cultural contexts. At different stages of the process, the Key Words in Context (KWIC) tool was employed to test additional codes as the meaning and context of the words in use drew attention to some important themes, among them *Quality, Competitions, and Innovate/*

Experiment (Wutich and Gravlee 2010). Key words were coded for the sentence before and after in order to provide context.

2.4. Identifying Themes through Visualizations

A detailed coding of the first interview was conducted to begin this analysis in the sample study. One of the most common methods for identifying themes in early stages of analysis is identifying repetitions within and across narratives (Bernard and Ryan 2010; Weston et al. 2001). While open coding the first narrative, repetitions were identified and a grounded approach was used to note the emergence of new themes (Markovic 2006; Strauss and Corbin 1990).

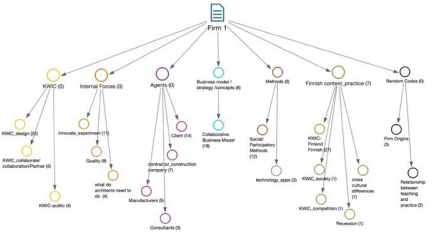

Figure 2. Single-Case Model with Code Hierarchy for Sample Study Firm 1 with modifications by the author for clarity

While researchers can build data visualizations in a freehand and additive manner, MAXMaps provides nine built-in model templates useful for initiating visual analysis. The Single-Case Model and the Single-Case Model with Code Hierarchy templates show which codes have been assigned to the document and their frequency can be expressed through symbol size, line weights, and numbers in order to quickly assess the document's content (Figure 2).

More useful for advancing inductive analysis is the Code Co-occurrence Model template, which focuses on intersections among a grouping of codes. Documents and codes are

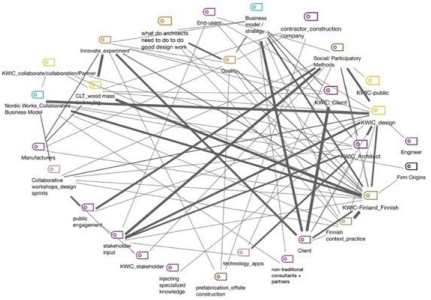

Figure 3. Co-Occurrence Model for Firm 1 as generated by the software. The Code Co-Occurrence model is useful for discovering interrelationships among codes but requires analysis and design agency to make meaning from the data

selected for inclusion in the model by activating them prior to creating the map. A minimum number of co-occurrences can be selected to focus on the most important relationships. These relationships can be amplified by setting the line width and code symbol size to register the frequency of overlaps. Within the model, the code frequencies can also be expressed numerically. In the Sample Study, the Code Co-occurrence Model was employed to render connections in the data visible. During the first coding process, the author identified a set of themes concerning the business, technological and social/ participatory methods the interviewee employed to collaborate. Another grouping of codes was

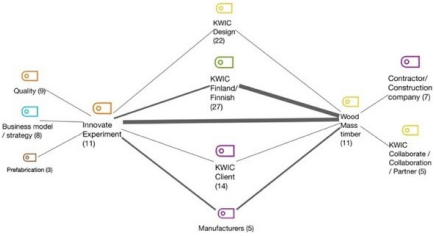

Figure 4. Focused Code Co-occurrence model exploring the codes Innovate/Experiment and Wood/ Mass Timber

identified that concerned the interviewee's understanding of the phenomena of engaging in fruitful collaborations and achieving positive design outcomes.

Building hypotheses by employing relational visual maps is an iterative process. If a large selection of codes are initially activated, the map generated by the algorithm provides a dense and often unwieldly web of code interrelationships (Figure 3). One strategy is to build simpler maps containing fewer codes in order to confirm the relationship among themes. For example, a focused Code Co-occurrence model (Figure 4) looking at the strength of the relationship between the codes "Innovate/Experiment" and "Wood/ Mass Timber" confirmed the author's hunch that when the first interviewee discussed Innovation and Experimentation, they also frequently discussed the role of Mass Timber in their work and referenced the importance of design, the Finnish context in which they operate, and their relationships with clients and manufacturers. Iteratively studying smaller confirmatory clusters is an analytic action focused on data reduction which can, as more complex maps are constructed, help to eliminate non-productive codes.

This visual analytic process simultaneously balances data reduction and data display. If too many codes are activated, the relationships can be overwhelming and not conducive to theory-building; if too few codes are activated, the webs are not sufficiently thick and important relationships may be missed. Organizing the codes into clusters and clarifying their interrelationships requires actively engaging the software and making analytic decisions when rearranging the elements in the workspace. Once the selectively edited codes are organized into areas of interest, the attendant graphic and thematic hierarchy can contribute to more complex, yet orderly, exploratory maps. In the Study Example, an iterative process building maps of increasing clarity identified salient thematic patterns among the coding clusters (Figure 5). These central tendencies were each explored further in new maps as additional transcripts were coded.

The next step involved exploring clusters of codes by exposing the underlying text. Revealing the text provided an opportunity to engage in further analytic techniques akin to a software-supported version of traditional manual cutting and sorting methods (Bernard and Ryan 2010). This step enables researchers to rule out concepts that might look similar due to code co-occurrence, but are not actually quite as related once the associated full text is visible; the ensuing code clarification can prompt revision of inclusion and exclusion criteria. Further, the process of analyzing the text associated with the linked nodes made apparent some repeating key words from the Study Example transcripts. These discoveries activated a new round of analysis employing the Key Word in Context (KWIC) technique in which, supported by the software, additional text units were coded and then added to the model. The initial codebook was further refined and a revised visual map was constructed to establish relationships among the major themes. (Figure 6) After reaching conceptual exhaustion from coding this first interview, themes from the first interview produced a series of hypotheses, which were then tested, modified, confirmed, and expanded in subsequent interviews (Markovic 2006).

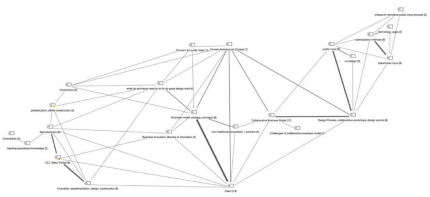

Figure 5. Revised Co-Occurrence Model for Firm to spatialize code clusters and identify areas of theoretical interest.

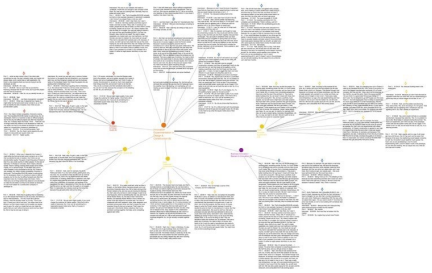

Figure 6. Co-Occurrence Model with Select Text Clusters Exposed

2.5. Visualizing Systematic Comparisons

One method for analyzing narratives that can produce a high number of themes early in the analysis process is looking for similarities and difference within and across narratives (Bernard and Ryan 2010). Searching for similarities and differences by making systematic comparisons across units of data brings a focus on the data itself and is a way to bypass the researcher's assumptions (Strauss and Corbin 1990). In this Sample Study, interviews continued to be coded in the order that the firms were interviewed. After open coding each narrative, MAXMaps and the Code Matrix Browser were employed to compare the themes among the interviews.

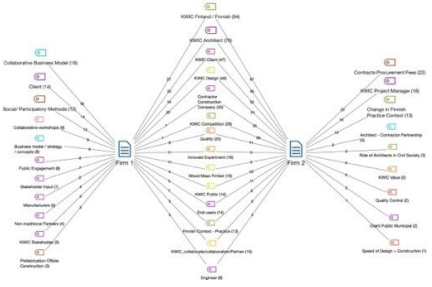

Figure 7. Two-Cases Model exploring similarities and differences in the first two transcripts.

The Two-Cases Model is particularly useful for visualizing relationships among two documents as it quickly demonstrates the strength of overlaps and renders codes spatially so that outlying codes are easy to identify due to position. In the Study Example, this exercise showed the growing importance of the codes for *Quality, Wood, Competitions, and End-Users* but it also made clear that while the first interviewee spoke extensively about their innovations in collaborative business strategies to achieve their design goals, the second interviewee focused on the importance of setting up contracts and procurement strategies that would support their design objectives. (Figure 7) The similarities and differences discovered prompted further refinement and reorganization of the Codebook. As more transcripts are coded, the Code Matrix Browser provides a graphic and numeric assessment of which codes have been assigned, how frequently, and in which documents. Though it is more difficult with the Code Matrix Browser to directly interact with the underlying data, these visual representations of code distributions help to identify patterns, as well as exceptional cases, and can thus serve as a useful validation technique.

2.6. Building Hypotheses

Once the data set is fully coded, individual codes and code relationships can be explored in a more focused fashion by building maps to investigate specific codes of interest. Exploring their code co-occurrences graphically can play an integral role in hypothesis generation. In the Study Example, a quote from an interviewee concerning the importance of wood in public architecture sparked an exploration of the associated invivo code. Mapping the code co-occurrence for key words associated with wood architecture, such as CLT, mass timber, and log, enabled a consideration of the interwovenness of technical methods with a building material that carries meaning

in the Finnish culture, building traditions, and contemporary economy. Another exploration concerned a central tendency of the narratives—that *Quality* and *Innovation* come from direct participation and involvement with the *End Users*. The relationship between *End-Users* and *Innovation* was investigated by building a visual map exploring code co-occurrences. When generating maps to advance theory building, it may be helpful to first set up binary relationships before making more complex maps. While earlier iterations considering a three-way exploration of the codes *End-Users, Innovation*, and *Quality* proved difficult to read, a map looking at the expressed relationship between *End Users* and *Innovation* provided more clarity.

3. DISCUSSION

While qualitative researchers have called for a greater role for visualization in conducting empirical research (Ravasi 2017) and have urged a more inventive and iterative stance towards their generation and use (Miles and Huberman 1994,11), there are few resources to help researchers bridge the gap between the instructions found in software manuals and the path to useful data visualizations. This paper contributes to the literature by providing an outline of strategies to iteratively use visual tools for codebook development and theory building. These strategies may be particularly helpful for qualitative studies situated on the exploratory end of the exploratory-confirmatory spectrum (Wutich and Gravlee 2010). Employing visual maps as a central feature in the ongoing "materialization of cognitive work" (Stigliani and Ravasi 2012) challenged previous assumptions about the research question and enabled development of more focused research questions for future study phases. As described in the Study Example process, the strategies suggests a refinement of Miles and Huberman's diagram of the Components of Data Analysis (Figure 1). The robust and interactive visual tools available in the CAQDAS software now support a process to bring data reduction and data display into a much tighter and more iterative relationship than suggested by the organization of components depicted in the original diagram.

Visual modes of representing, thinking and communicating may pose a challenge to qualitative researchers who generally prioritize linguistic and text-based data in their work. However, the centrality of visual materials in the knowledge-intensive work of built environment practitioners (Whyte and Ewenstein 2007) position architects and designers to be adept at using these tools to generate new forms of knowledge. The fluidity of moving between the underlying data and the emergent maps activates the pattern-synthesizing methods central to "designerly ways of knowing" and facilitates designers' orientation towards "constructive" modes of thinking (Cross 1982). Further, the visual tools promote the translation of established design practices into social science methodologies. For example, designers typically rely on practices such as seeing thoughts and ideas as they are being worked on, and physically moving materials around to detect commonalities and emergent themes (Stigliani and Ravasi 2012). As the literature on codebook development frequently addresses the need to develop shared understandings of phenomenon among members of research teams (Weston et al. 2001; MacQueen et al. 1998), visualizations may prove invaluable as they have a history of use in design practice as exploratory objects for shared project framing, knowledge development and meaning making (Whyte and Ewenstein 2007). Cross pollinating social science and design methods by using visual tools for systematic analysis adapts and expands both of these methods' sensemaking capabilities (Weick 1995; Krippendorff 2006) as well as their prospective sensemaking potential (Gioia and Mehra 1996).

CONCLUSION

This paper contributes to the discussion regarding methods architects and designers can employ to strengthen hypothesis building when working with qualitative data by demonstrating the use of visual qualitative data analysis tools. In the drive for continual advancement of research methods to improve the human built environment, this paper argues that that visual tools available in CAQDAS software position designers to build on their disciplinary expertise in order to more meaningfully contribute to impactful research.
