PAPER #7.12

SOCIAL RENTAL HOUSING SITING & MAINTENANCE: CONSIDERING THE ARCHITECT'S CRITICAL ROLE

Chika C. Daniels-Akunekwe [a], Dr. Brian R. Sinclair[b]
[a]University of Calgary, Calgary, Alberta, Canada
[b]University of Calgary, Calgary, Alberta, Canada, + sinclairstudio inc. Alberta, Canada

ABSTRACT

In several countries across the globe, social rental housing (SRH) is lost for a variety of reasons. In Nigeria, SRH, a housing type typically associated with the most disadvantaged people in the society, is lost due to reasons predominantly associated with siting and maintenance (Daniels-Akunekwe & Sinclair, 2018). Although, SRH constitutes just over 5% of the total housing stock, a significant amount of these developments are *still* lost. To address these issues, in several contexts – including in Nigeria, the responsibility is accorded the architect, who is considered the chief culprit. This is because historically architects have been charged with overseeing building processes from inception to completion; their responsibility spanned beyond the breadth of the structure's aesthetics through to successful construction and even liability for its failure. Now, the profession has morphed into one of intense specialization, where the role of the architect seems to be reduced to design – the role of a "shaper"… of "form-giver" (Franck, 2017). Leaving architects to placate themselves with the opinion that designing is at the core of all things building, while being painfully aware that this is a "mere shadow of the competencies" they command, and a demotion from their roles as master builder and "generalist-practitioner" (Franck, 2017).

With the progressively narrowed/narrowing role of the architect, and the absence of a universally outlined description of the architect's obligations, it is difficult to establish in certain circumstances (where buildings are considered unsuccessful) the extent of involvement in the problem for which the architect is liable (Daniels-Akunekwe & Sinclair, 2019a). It is our suggestion that the characteristic extremely limited budget of SRH projects should confer on the architect, the additional responsibility of artist, researcher and anthropologist… to not only design an adequate, affordable, and aesthetically pleasant development but one that considers the location, and post-construction life, with equal intensity.

Therefore, riding on this reasoning, we select four SRH developments situated in non-poor (both middle and high-income) neighborhoods in Lagos city, Nigeria. These cases were selected because despite being located in 'choice' neighborhoods, the specific sites combined with a non-existent/non-effective maintenance management program have proved unfavorable and unbeneficial to its occupants, the surrounding residents, and to the neighborhood as a whole. By deploying mixed methods including literature investigation, interviews, and phenomenology, the study seeks to define to which extent siting and maintenance are related to the profession of the architect.

KEYWORDS

Social housing; siting; maintenance; design; architecture.

INTRODUCTION

> "It is hard to argue that housing is not a fundamental human need. Decent, affordable housing should be a basic right for everybody in this country. The reason is simple: without stable shelter, everything else falls apart." - Matthew Desmond

Historically, social housing (SH) is believed to have originated in Europe and over the years, as it has spread across the globe and taken on myriad forms, what it means has evolved [United Nations Economic Commission for Europe (UNECE), 2006, 2015; Organization for Economic Co-operation and Development (OECD), 2016]. This is because "each country has forms of housing that are broadly designed to satisfy the needs of households who are unable to compete in the marketplace for housing of an acceptable standard" (Oxley 2009, 2) therefore terms like public housing, common housing, limited-profit housing, government subsidized housing, and not-for-profit housing etc. are now used interchangeably (UNECE, 2015). As a result of this, the UNECE (2015) defines SH as essentially being a "key word used to enable governments and interested stakeholders to exchange knowledge about the part of the housing system that is aimed to satisfying need, that is supported by the state and distributed through administrative process distinct to their local contexts" (UNECE 2015, 14). A more specific definition is that provided by the Canada Mortgage and Housing Corporation (CHMC), which describes SH as:

> an umbrella term referring to rental housing that is designed to cater for the needs of people on very low to moderate incomes who may be experiencing 'rental stress' in the private market" (CMHC 2017, para. 3).

The allocation of SH is strictly dependent on the severity of the households' need (Whitehead & Scanlon 2007). SH is the singular public rental housing type that focuses on the most deprived group in the population (Polak 2007).

Unlike in Europe, in Nigeria, via the 2011 National Housing Policy (NHP) draft, the government redefined SH to connote "housing for no income earners, low-income earners and lower medium income earners" (Ekong & Onye 2013, 257), which was adopted. The NHP document defined the three classes to mean:

"(i) All persons whose income does not exceed the national average of 25% of the National Minimum wage [which is eighteen thousand naira (N18, 000) per month" (or USD49.25 as at February 2020)]; "(ii) all persons whose annual income exceeds the 'No Income' level, but does not exceed the National Minimum wage; and (iii) all persons whose annual income exceeds the National Minimum wage, but does not exceed four times the National Minimum wage" (Ekong & Onye 2013, p. 258).

SH in Nigeria is patterned after Western styles (Ukoha & Beamish, 1996), and was recognized as a vital housing development in the 1970s (Olayiwola et al., 2005). This recognition [where the government first made mention (specifically) of SH as a solution to the then budding housing shortage challenge] occurred during the period (1975-1980) of the Third National Development Plan (NDP); after which, the nation's first Low-cost housing (LCH) program was launched (Olayiwola et al., 2005). While, there is no confusion as to what SH means in the Nigerian context, researchers such as Ekong & Onye (2013), Ilesanmi (2010) and Ihuah & Fortune (2013) have interchangeably used the term SH with public housing in their papers (which essentially focus on SH in Nigeria). This substitution is seen to also exist in daily news publication on SH in Nigeria (Aboderin, 2017).

> "In spite of the different meanings and connotations of public housing in literature, there is consensus among authors and researchers as to the goal of social housing

> provision in most countries of the world… which is to ensure the provision of subsidized housing to households and individuals who are unable to gain access to decent housing at market prices" (Balchin et al., 2000; Liu, 2007 quoted in Ibem et al., 2011a; p. 423)...

and constitute a strategy that is pro-poor – created in order to ensure housing affordability (Yates, 2013, Aboderin, 2017). To this effect, rent is determined by tenant income and is generally set at 25 or 30% of household income (Yates, 2013). Contextually speaking (within the setting that is Nigeria), SH is an umbrella term, which covers a variety of tenures including: social rented/ rental housing, LCH, co-operatives, private-rented SH, and shared ownership housing (Ndubueze, 2009). Among these different tenures, LCH is the most dominant.

Having adequately described what SH represents in Nigeria and more broadly – in other contexts, the reason why the authors have selected this specific housing type is because in the last two-plus decades, SRH has been acknowledged as the "housing of the future" (Harloe, 1994; Maclennan & More, 1997; Delgado & De Troyer, 2017)…

> based on its ability to – when strategically situated in non-poor neighborhoods – exert minimal pressure on wages and salaries, create more livable and cohesive cities, and allow for shorter commutes and proximity to labor (Daniels-Akunekwe & Sinclair, 2018).

While considering the above statement against the situation in Nigeria, it is apparent that the latter is an antithesis to the promise that SRH proffers. Although SRH is not characteristic of the housing sector in the country, recent attempts at providing this housing type has resulted in a continued mirroring of a long-term pattern of vandalism and/or abandonment experienced with previous SRH developments (Ihuah & Fortune, 2013; Adesola, 2018; Yakubu, 2019).

As this is not an entirely novel study, previous research (which has been conducted on a larger/broader scale) has indicated existing links between the failure of the urban built environment and the role of the architect and his/her inability to lead other built environment professionals towards the creation of a holistically sustainable environment. In this more focused study (where we consider the changing the role of the architect, investigate to what extent this constantly changing role is impacting their ability to effectively perform, and to what extent the current issues impacting the success of SRH can be linked to the profession of the architect) however, the singular constant identified in the design and delivery of SRH and its continued inability to achieve its goal (that is, improve the lives of its inhabitant and create more liveable and cohesive neighbourhoods/cities) is the architect (Daniels-Akunekwe & Sinclair, 2019), who in the Nigerian context, is expected to be the leader of the built environment professionals (Allu and Elimisiemon, 2017), and, in addition to…

> traditional roles of design and specification, … also contribute through training and education; research and development; public enlightenment; and advocacy (Opoko 2015).

While this is expected from the architect, it has not necessarily often translated to what is delivered. The expectation from the architect in the Nigerian context is not atypical but rather is in alignment with studies by Allen (2009), Cheshmehzangi and Deng (2016), and Tan et al. (2017), which stipulate that sustaining all parts of the built environment *should* indeed be the responsibility of the architect.

1. UNDERSTANDING THE RELATIONSHIP BETWEEN THE (ROLE OF THE) ARCHITECT AND THE TWO MAIN ISSUES IDENTIFIED WITH SRH

This section provides background and historical information on the themes around which our study anchors. In the following sections, we attempt to review and understand: (I) the historical expansion and/or reduction of the role of the architect; first, generally, and secondly, as it relates exclusively to pro-poor housing, (II) the training process required for the architect in order to ascertain if they are (continually, to present day) furnished with the skill set to manage more than just design, (III) the role of the architect in the production and provision of SRH, and (IV) the architect's role as it pertains to the siting and maintenance of SRH in Nigeria.

1.1. The historically changing role of the architect: 'Jack-of-all-trades' or specialist?

> "The jack-of-all-trades seldom is good at any. Concentrate all of your efforts on one definite chief aim." – Napoleon Hill

The architect was traditionally referred to as the master builder (Kahn, 1979). In fact, the term architect was derived from ancient Greece where *Arkhi* meant head chief or master and *tekton* meant worker or builder (Berman, 2003). Architects such as Michaelangelo and Leonardo da Vinci are exemplary of the…

> omniscient master builder who was charged with the responsibility for the total success of a construction project. In this role the architect not only graphically portrayed the basic concept of the aesthetic and structural components of an edifice, he also took charge of its implementation, and was liable for its failure (Kahn 1979, 216).

Because of this history, the word "architect" carries with it preconceived notions (Faraudo, 2019); that the architect *must* bear the entire responsibility for both project design and project construction from inception to completion (Franck, 2017). As a result of the breadth of expectation from the architect, he had sufficient design and construction proficiency to undertake the entirety of his responsibilities (Burr and Jones, 2010). Between then and now, over the last couple of centuries, the role of the architect has continually evolved (Burr and Jones, 2010). The profession has morphed into one currently characterized by intense specialization so that the entire process of building design and construction is segmented to provide the different professions within the building and construction industry clearly defined roles. The master builder of the past, in many contexts, is now fundamentally considered to be the "designer" and "accorded very limited responsibility regarding the outcome of the entire endeavour" (Franck, 2017). While researchers can agree that the role of the architect has changed considerably, and is now significantly narrowed, it is commonly unclear as to their exact role.

There are several reasons why the role of the architect has narrowed. One of which, and perhaps chief among them, is the increased complexity of construction (Jones, 2006; Burr and Jones, 2010). As building projects become more technical, increase in scale, adopt new technology, incorporate myriad systems, are subjected to increased "time pressure, dangers of liability, of lawsuits regarding malpractice…" (Franck 2017, para. 4) the notion that the architect may be unable to maintain an expertise level to accommodate all the trades and aspects of the building continued to arise (Jones, 2006). Eventually, this led to the *splitting* of the master builder role into two principal professions/professionals; the designer and the builder, with the architect exempted from building activities (Jones, 2006; Thomsen,

2002). Even within the design section, further specialization resulted in the identification of additional architects or designers to attend to "landscape, interior, and acoustic…" (Woods, 1999). With specialization came intense fragmentation, which has evolved to the point where, rather than the architect single-handedly assuming the responsibility for an entire project,

> It is not uncommon today to have an architect with 15-20 consultants, a general contractor with 40-60 subcontractors, and subcontractors with hundreds of manufacturers and suppliers (Jones 2010, 3).

This fragmentation has also accommodated the creation of and inclusion of new roles within the industry such as the construction manager, who has inadvertently become the principal agent for the construction process. The arguments surrounding the creation of the construction manager profession/position were predominantly along the lines of: (I) the architect being too much of a designer (with a focus on aesthetics) to manage a project from inception to completion, and/or (II) the outright inadequacy of the architect in construction management services (Berman, 2002; Yates, 2003). This arrangement is fraught with its own problems, and while it does address some of the general concerns with burdening the architect with excessive responsibility, issues around the "confusion of definitions and conflicts of roles" continue to emerge. Once again, the architect is routinely left without a clearly defined role or position.

1.2. The contextual variance in the architect's role: is broader better?

While the role of the architect is seen to be generally narrowing, in countries such as: Australia, Austria, Netherlands, Uganda, in terms of pro-poor housing, the role of the architect appears to be broadening (Salcedo and Straub, 2014; Adengo, 2017).

In the Netherlands, according to Salcedo and Straub (2014), based on their study of 21 SH developments, results revealed that projects typically employ the services of an architect and a main contractor; along with consultants and advisors, but the former is *still* expected to take on responsibilities larger than just designer – responsibilities that are technical and advisory in nature. In Austria (Vienna), the development of SRH requires the services of the architect, who should also be versed in urban planning, and to a significant extent, ecology and social policy. The rationale behind this is that more important than good design, is the relationship with that design to its surroundings (Forster, 2018).

In Australia, the architect and his architecture are critical in the delivery of pro-poor housing (Maher, 2017). Before the 70s, the contribution of the architect (via design) towards the delivery of SRH was "most overlooked" (Maher, 2017). After the 70s, a new era began where the government and architects began working together towards providing SRH. As a central part of the built environment, the Australian government recognizes and has openly declared that the architect remains relevant through to completion. The Australian government states that the architectural profession is able to handle crucial issues that can *genuinely* deliver affordability, sustainability, and housing flexibility, "in both upfront costs and the on-going cost of occupation" (Maher 2017, para. 19).

Across Africa, it is not atypical for architects to *persuade* the community, their clients, and colleagues in the design/construction sector that their profession should exceed design, in Uganda however, stakeholders require little to no persuasion. As it relates to SRH, while the architect is expected to have an "entire technical team on board, including engineers, quantity surveyors and land surveyors" (Adengo, 2017), the architect is still expected to "wear all these hats simultaneously" (Adengo, 2017). Even the misconception that the service of the architect is unnecessary

during the construction phase is very seldom debated in the context. In fact, it is popular opinion that without the architect's presence through to project completion, the construction manager may tend to make discretionary changes and take

> shortcuts that may lower the quality of the outcome of the project; the result of which can be seen in the recent building collapses in Kampala (Adengo 2017, para. 3).

SRH building collapse has been known to happen in Uganda because the architect "plays too broad a role in the initial design process, but too small a role during construction" (Adengo 2017, para. 4). Research indicates that this broadening of responsibility in various contexts is on account of the characteristic extremely limited budget of SRH developments. The nature of this budget confers on the architect the duty to not only design an adequate, affordable, and aesthetically pleasant development but one that considers the location, and post-construction life with equal intensity. Therefore, the architect must – in addition to designer - also be artist, researcher and anthropologist. If all this expectation is piled on the architect, it is important to consider the quality of training that is provided for and required from him in order to deliver his responsibilities.

1.3. The training process for the architectural profession

Architecture education in Nigeria commenced in 1952 with the establishment of the first School of Architecture at the Nigerian College of Science and Technology in Ibadan (south-eastern Nigeria). Three years after which, the School was relocated to its northern campus, located in Zaria. Initially, the 5-year program culminated in the award of a diploma and the qualification to write the Royal Institute of British Architect (RIBA) examinations but soon after the College was upgraded to a "full-fledged university", rather than diplomas, it began to issue Bachelor of Architecture degrees (Maina, 2008). By 1969, Nigeria had adopted and implemented a 2-tier B.Sc/M. Sc 'American-styled' program, which is still in existence in many Nigerian Schools today. Globally, in order for the architect to practice, he must obtain a license, which follows the acquisition of a graduate degree from a college that has been accredited by the designated national accreditation board, as well as a mandatory internship program and architectural exam (Jones, 2006).
Acquiring an architecture license is designed to be lengthy, tough and demanding [particularly from the student perspective (Dare-Abel et al., 2015)] in order to be adequately equipped for a career-long gruelling journey "characterized by long hours of design, drafting, and modelling" (Dare-Abel et al. 2015, 169). While the entirety of the architect's education is not gained in the school of architecture, it is critical to afford the student a solid foundation for all future learning.

1.4. The architectural education: expectations versus what is obtained

Architectural education worldwide is fundamentally a multi-disciplinary program, which integrates essentials from urbanism, structure, building physics, real estate, construction, services, etc. The multi-disciplinary nature of architecture exists predominantly in the undergraduate degree in order for the individual enrolled (during the typical 5-year period) to decide on a specialization (Moonen and Veeger, 2014). To understand why architectural education is relatively encompassing, it is necessary to appreciate that architecture exceeds design, building and even construction, to
the improvement of the human habitat. Thus, the goal of architectural education, which is essentially to advance the profession of architecture, is to contribute to the attainment

of a humane and responsive environment (Magaji and Ilyasu 2016, 13).

Similarly, a notable architect in Nigeria; Arc. Ibrahim Haruna, in the annual Architects Registration Council of Nigeria (ARCON), expressed and emphasized that the nation's expectation of architects is to shape and re-shape the built environment. Despite this premise, architectural education in Nigeria is increasingly falling behind in comparison to international standards, with regards to both training and output, because it has become stale (Dare-Abel et al., 2015; Magaji and Ilyasu, 2016). Considering that architectural education in Nigeria is just over seven decades old, it has remained regressive when compared to other countries that have taught it for significantly longer periods (for centuries), and still have kept up with the globally changing rules around becoming "skilled and work-ready" (Onyegiri et al 2014, 65). In the last 50-plus years, schools of architecture in Nigeria, have left architectural programs; "studio learning culture, and its underlying rituals and processes" (ibid.) unchanged. This neither implies that the government is unaware nor that it fails to set standards. In fact, according to Dare-Abel et al. (2015), following the lead from the American context, it is the intention of the Nigerian government to continually reform the education system by incorporating both globally and locally tested solutions as is evident in the Third National Development Plan (NDP) but despite the intention, there is a mismatch in execution.

While the expectations for and results of (in terms of service delivery) the architect do not correspond, the attraction to an architectural degree remains high. Over the last 17 years (2003 to 2019), the graduates from the fully accredited (to Masters level) Nigerian universities is recorded as just under 13,000 (Nairaland, 2020; ARCON, 2020). Despite this large number, only an average of 100 students are registered annually (ARCON, 2020). With an opportunity such as that present in Nigeria, where (I) the population is over 206 million (World Population Review, 2020), (II) there is a rapidly increasing rate of building construction, and (III) the nation has only 3,500-plus registered architects (ARCON, 2020), there is a huge prospect for architects in Nigeria. Additionally, in 35 years, the number of registered Architectural firms has risen from 38 to 649, with a larger growth ascribed to the firms that are "unregistered by the professional bodies but are licensed by the Corporate Affairs Commission (CAC)" (Dare-Abel et al., 2015). According to Njoku (2011), while this huge growth in the establishment of architecture firms is representative of the relevance of the architecture profession and architectural services in the country, it is not representative of how much architectural services are actually being utilized. Also, because Nigerians are constantly seeking foreign architects, it does not mean that locally trained architects are incompetent rather the opposite is the case, "there are a lot of Nigerian architects who can do the job better than foreign architects" (Njoku, 2011), but Nigerians typically recruit expatriates over the millions of job-seeking Nigerians.

By simple extrapolation, the opportunity presents a ratio of one (registered) professional architect to service over fifty eight thousand Nigerians. With the majority of these Nigerians being poor or of the lower income class, it is important that architects are trained, not just for the specific context where they practice but also to address the needs of and design for all income classes.

Having established several elements: that (I) the education level may not have improved in Nigeria in the last several decades, (II) despite the former, the level of architectural education in Nigeria is still able to produce architects who are relatively skilled and capable, and (III) the architect is increasingly relevant and operational considering their ability to cater to the rapid construction rate in the city/country, we then conjecture as to what the issue may be with churning out successful SRH projects. As we build on the suggestion

that the architect is the major concern with developing adequate SRH (in terms of siting and maintenance), we consider what makes the architect; that which enables him perform in his role, which is the quality of education. We will briefly review the quality of architectural education with regards to the curriculum.

1.5. Curriculum for architectural education

There are several elements that make up quality architecture education; some of these are: intake/admission requirements, teaching quality, (awareness about) transition from student to professional, professional practice, keeping pace with trends and technology in architecture [such as increasing the proficiency of students in the use of Computer Aided Design (CAD)] but by far the most important is curricula (Maina, 2008; Dare-Abel et al., 2015). In 2012, Joanne Banks identified four pathway standards for all students in order "to raise performance and close achievement gaps", and they all revolve around curriculum. In fact, Magaji and Ilyasu (2016) describe curriculum as the entire educative process including the "environment, student, lecturer, course, course content, method, and physical and psychological environment" (15).

Based on reviewing studies on similar themes, the curriculum of architectural education in Nigeria has "largely remained the same" (Maina, 2008) since the 60s. This stagnation has persisted despite the massive global evolution that has occurred with the discipline and has also resulted in the insufficiency of the courses taught to furnish the students with the knowledge required for a professional career. These courses, which are required to be fundamental to providing the springboard for success, are failing to prepare students for real-life situations (Maina 2008, 3). Besides the ineffective course content within classrooms, students are also failing to acquire the requisite skills during the mandatory Industrial Training (IT) program (ibid.). While this is not a problem of the educational institutions per se but of the Architectural councils (the policy making bodies for architects in Nigeria) in the country, there remains a responsibility of tutelage from participating architecture firms to the student, in order to fulfil this portion of the curriculum. Additionally, allied courses that aim to produce a well-rounded professional such as the knowledge of building materials, electrical and mechanical services and drawings, and in some cases, Masters degree programs, are increasingly inadequate. Another point Maina (2008) makes is that the Nigerian curriculum, which was based on the British/American program, is now out of touch with providing the know-how to deal with the nation's current prevailing problem of squatter settlements, of minimum cost housing, of slum renewal and many of those problems usually associated with the developing countries (Adeyemi, 2000).

2. THE ROLE OF THE ARCHITECT IN THE PRODUCTION AND PROVISION OF SRH

> "Architecture is really about well-being. I think that people want to feel good in a space… on the other hand, its about shelter, but its also about pleasure." – Zaha Hadid

This section of the paper seeks to understand the role of the architect in the production and provision of SRH and attempts to draw a connection between their responsibilities in this regard and how it could be accountable for the siting and maintenance issues highlighted in Nigeria.

2.1. The architect's role in SRH production and provision

The historical role of the architect in the production and provision of pro-poor housing has been limited to design. Within this already limited responsibility, the design produced by the architect was/is sternly impacted by the

government (Cheng, 1980; Nimmo, 2001). The rationale behind this is the government's insistence that the design of SRH has to follow a defined conception; SRH had/has to be stripped of unnecessary extravagancies, and could not be anything above the bare minimum. What the government insisted on was characterless, high-density blocks and "if the architects employed… proposed anything else, they will have a battle on their hands" (Nimmo, 2001). There was/is no encouragement…

> to pursue quality design solutions and an outright resistance to innovation, especially if that means that the housing might be different to what surrounds it (ibid.).

Interestingly, in many contexts, SRH design proposals outside of these limitations will typically be unsupported. The brief is simple "do not design the very best you can" (ibid.). When you consider what design means to an architect, this expectation is both strange and difficult for him, and an antithesis to what the profession represents. The result of this is that what the architect delivers is not truly his but rather a 'brainchild' of the government.

Despite this being the case in Nigeria, in many countries (Netherlands, France, Spain, Slovenia, Australia, Belgium, Italy) across the globe, the architect is encouraged to produce the finest design while still prioritizing affordability. In fact, in Austria (Vienna), two things have begun to transpire: (I) the government has begun to seek star architects to design SRH, and (II) the mention of upcoming SRH projects has begun to attract an "impressive list of 'star' architects as a way to demonstrate the importance of the development" (Forster, 2018).

2.2. The architect's role in the siting and maintenance of SRH

The government's focus on cost issues has significantly distracted it from issues such as siting and maintenance, which are guaranteed to impact its performance. In cases where the architect has access to and perhaps, also consults the end users, little can be done in terms of incorporating their suggestions into the design proposal.

Typically, the siting of (government provided) SRH is beyond the responsibility of the architect. If the government assumes responsibility for developing the SRH structure, it would provide the land, thereby determining where the development is situated. This is the case in Nigeria, where the Nigerian government is responsible for allocating land for SRH (Ajayi et al., 2014). Again, because the government's focus is on cost saving, the land allocated for SRH, is characteristically located in poor, blighted fringe neighbourhoods. 70% of all SRH is located in such neighbourhoods (ibid.). Literature shows that there is no slated location for siting SRH on record; and if SRH were to be developed privately, permission to proceed would still be sought from government authorities (Isah, 2016). There are however, a handful of scenarios where the government has allocated high-demand, high potential, and profitable land to SRH – some of which we highlight later on in this paper. Although, land selection and siting may not be the architect's responsibility, the argument can be made that based on the skills acquired from an architectural education, the architect is equipped to manipulate the environment to elevate the SRH development and apply their knowledge of planning, urban design etc. as tools to marry the existing environment and the SRH development.

Still there are instances in Nigeria, when the Architect is consulted by an individual/party within the private sector, with the intention to develop some form of pro-poor housing. Adewunmi (2016) discusses two routes that

are typically taken following the decision to develop land towards the provision of SRH: one, the individual/party, based on counsel from professionals within the building and construction industry (the architect included), is advised on the 'right' location to seek out and purchase land prior to embarking on design and construction, or two, the individual/party identifies a parcel of land that they consider favourable (for myriad reasons: some being affordability, location, size), purchase it, decide to develop a variation of pro-poor/mass housing, and then proceed to hire an architect, who at this point is (and can only be) responsible for siting decisions (going forward) that are limited to building orientation, vehicle access (integration), physical barriers, landscaping, parking, and protection of utilities to mitigate threats, among other things.

Interestingly, while there are neither current nor comprehensive documents explicitly describing the mechanisms through which the allocation of sites for SRH in Nigeria take place, Ilesanmi (2010) provides an idea based on what transpired in the late 70s/80s. The government earmarked land for the construction of pro-poor housing, specifically (variations of) public housing. For any corporation or interested party to secure land for the development of LCH (etc.), an application had to be submitted through the Land Use and Allocation Committee (Ilesanmi, 2010). The application process was cumbersome, and the administrative process, demanding and a major constraint to propagating the development of all kinds of public housing schemes. The major requirement following acquisition was confirmation of the development of massive scale housing for low-income groups (ibid.).

Like land allocation and siting, the maintenance of SRH was the responsibility of the government (Isah, 2016). SRH maintenance is considered to be so burdensome [because it spans beyond the building itself (that is, its efficient performance, physical appearance, and economic returns/value), and its users to the surrounding environment] that developments (Ihuah & Fortune, 2013)…

> are abandoned either half way to completion, after completion, or not even embarked on as a result of there being no framework to address it (Fatoye & Odusami, 2009)

Despite the enactment of several housing policies that emphasize the need for both a planned and an unplanned maintenance policy, Nigeria's notoriety for having a poor maintenance culture remains unchanged (Ihuah et al., 2014). As far back as in 1991, a review completed by the Federal Government indicated that the backlog of maintenance required to bring the existing units to acceptable standards was equivalent to the cost of three million new units [Federal Republic of Nigeria (FRN), 1991]. As a result of the severity of the maintenance challenge, recent policy discussions papers have suggested the transference of the responsibility of maintenance to the inhabitants of the development as part of the government's plan for an operational subsidy (Isah, 2016). The argument the authors make here is that because maintenance is crucial yet expensive, the architect through design, and allocation/selection of building materials, can address some maintenance issues. The architect, through his craft, is required to produce sensitive, aesthetically pleasant and sustainable design proposals. One element within the sustainability bracket speaks to the 'maintainability' of that design. This implies that – to an extent – there is a responsibility conferred on the architect to ensure practicality, durability, and 'repair-ability'. Research reveals that scenarios where the SRH design has indicated finishes or materials (which proved efficient), there has been a direct impact on reducing loss on that property. It has also resulted in easier to maintain units/developments, "better retention of tenants, and a positive financial reserve to operate and maintain the property" (Jubany, 2011).

3. A REVIEW OF THE FOUR CASES IN NIGERIA

The four SRH developments selected for our study are: (I) Jakande low-cost housing estate, Lekki, Lagos *[speculated to be completed in 1988, 125 housing blocks/686 total housing units]* (II) Jakande low-cost housing estate Amuwo-Odofin, Lagos *[completed in 1992, 488 housing blocks/between 2,948-3,106 total housing units]* (III) Jakande low-cost housing estate, Surulere, Lagos *[speculated to be completed between 1972 and 1975, 226 housing blocks/1,356 total housing units*], and (IV) Shagari (Federal) low-cost housing estate, Ipaja, Lagos [completed in 1983, 125 housing blocks/1,514 total housing units]. Among the 23 SRH developments in Nigeria, we selected these four that demonstrate explicit and implicit links between our research purpose and objective, which are also large enough to highlight the issue being explored, and are situated in 'choice' neighbourhoods. The latter is crucial because there is research that shows that locating (any kind of) public housing in poor neighbourhoods is tantamount to propagating poverty and the negativities associated with the poor. On the other hand, there is research that shows that there are income benefits and character change associated with residents of public housing when the development is situated in non-poor neighbourhoods. Research also opines that such developments have a higher possibility of being afforded care and are typically better maintained than those in poor neighbourhoods.

Limited research findings and development details exist, pertaining to SRH in the Nigerian context, that have been documented for public & scholarly access. That said; the researchers during on-the-ground work in Lagos have accessed certain information typically pertaining to some statistical/ logistical aspects of SRH project – however, clarity around more nebulous dimensions, such as posturing/policies around ethics and professional responsibilities remain scant and largely inaccessible. What we discovered however, in all four neighbourhoods was fundamentally consistent. The Nigerian government was heavily involved in the entire process from design to construction such that the architect's role was to put the government's concept on paper so that the final design was essentially the governments'. This included the choice of building materials; cheap building materials (Olurode, 2009), which was again, a reflection of the governments' weighty influence in the process. At the time, with poverty rising and housing becoming expensive, the developments were "cheaply built, but were of great value" (ibid.) to the population. There are arguments however, that because the government had taken on a vast amount of projects running concurrently such as: schools, medical facilities, and a metro line for mass transit, that in order to deliver the 30,000 housing units provided, the government had to resort to the use of substandard building materials (ibid.). There are also arguments that the "excitement" surrounding such a novel endeavour at the time was overwhelming for the existing residents that there was little concern, through the period of execution, about the sustainability of the project (ibid.). Furthermore, being the pioneering developments when these SRH estates were constructed, there were no benchmarks for the country to aspire to or local precedents to inform the residents. Ever since, SRH has continued to be built in much the same way, that is, with (I) substandard materials founded on the excuse of too little funding, (II) the intention to achieve more housing units with less expenditure, and (III) the plan to institute and/or improve the maintenance program upon project completion, etc.

Idea-Relation Model

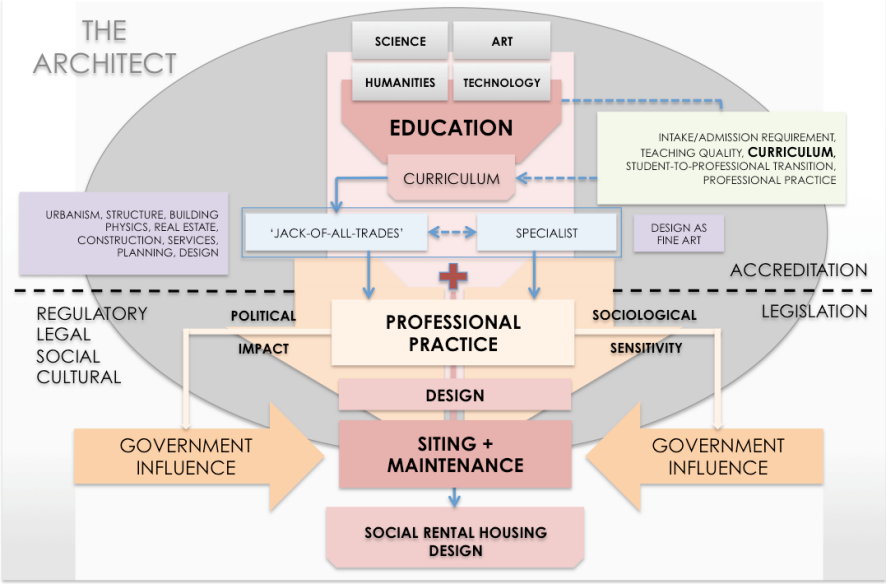

Figure 1. Ideal-Relation Model

CONCLUSION

> "… An age of greed has made it so that the architect no longer feels a duty to society." – Richard Rogers

Having already established the poor architectural education standards, demonstrated the architects limited role in the production and provision of SRH, as well as in its siting and maintenance (as a result of substantial government involvement and the typical tight budget allocated to this housing type), discussions with stakeholders [officials in the local government offices affiliated to and/or overseeing the four cases we studied, planners, developers (with experience erecting SRH developments), and residents of the non-poor neighbourhood], revealed an angle that has not been (well) explored in our context. The absence of two interlinked elements: (I) the architect being unaware how vital a role he *actually* plays in maximising siting and minimizing maintenance, and therefore, the overall outcome of SRH developments, and (II) the architect's social insensitivity.

While the architect may not have free reign in executing his duties, he is not exempt from complicity. In Iliopoulou's 2015 paper, she emphasized the architect's role as a 'double agent', which she explained speaks to their role as designer being as important as their social responsibility to the community. Despite the limitations in any context, she argues, as does

Jubany (2011) that the architect must never sacrifice his duty to represent the voice and needs of the people in an attempt to design insensitively. Social sensitivity speaks to the knowledge that his design is able to create a more civilized community by making a place more livable, affect quality of life, "influence social conditions, and cause positive social change" (Jubany, 2011). It also extends to championing ideologies that achieve the above, over alternate design that disregards focusing on the above-mentioned elements. The implication of this is that there is an expectation from the architect that rather than designing buildings that are bound to deteriorate/fail from the onset, and put financial pressure/strain (and otherwise) on the occupants (specifically the poor), their education, and ability demands that they refuse to comply and never compromise on quality. The problem, we speculate, is that the Nigerian architect has not fully come to understand their social responsibility. This obliviousness was recorded several decades ago when it occurred in the United Kingdom ensuing a dichotomy among architects, where there was a group of architects that created designs that had been inspired by, or advocated social struggles, and the other that triggered societal struggles, and prioritized/favoured practice and 'having work' (Iliopoulou, 2013). This dichotomy is currently being experienced in Nigeria, with the greater portion of architects more focused on practice. The result of this focus on 'having work' is reflected in how SRH has continued to manifest in the country, that is, poor siting/use of the location, and poor or inexistent maintenance program, which has in turn resulted in abandonment and vandalism, and more commonly now, building collapse (Hamma-adama and Kouider, 2017; Okagbue et al., 2018).

In the European context, the architect's education has evolved according to their responsibility and alongside advancements in technology (Franck, 2017). Having identified that the previous responsibility accorded to the architect was quite broad (ibid.); the role has "been de-coupled from the realization of the building, and even from its constructive completion" (Franck 2017, para. 3). The Nigerian government needs to learn from other contexts, and must clearly define the architect's role in its plans for providing SRH. If the architect is expected to design, then he should genuinely be allowed to masterfully execute his profession so that the outcome is indeed a real solution. The architect also needs to be taught, reminded and encouraged via the curriculum, during the mandatory Industrial Training and upon commencing practice, that architecture extends well beyond narrowly defined legislated practice.

PAPER #7.13

YOUTH DECARCERATION: USING SKETCH MODELS TO EXPLORE NON-PUNITIVE ATTITUDES

Julia Williams Robinson[a]
[a]School of Architecture, University of Minnesota, Minneapolis, Minnesota, USA

ABSTRACT

Many forces drive change in the youth incarceration system in the United States, including a newly appreciated need to treat youth offenders with trauma-informed care (Olafson et al 2016). In the case discussed here, the University of Minnesota, and Hennepin county in Minnesota, USA, interested in replacing the existing suburban youth correctional facility with community-based treatment facilities, worked together to explore the role of architecture in creating appropriate settings. The design of existing youth incarceration facilities despite intentions of rehabilitation and treatment, often conveys negative ideas such as punishment, privation and shame. The design studio asked how to design architecture that supports positive attitudes such as pride, hope, curiosity and safety? The focus of this paper is an exercise in which students were asked to explore different attitudes using sketch models.
Sketch models, rough, quickly made, ambiguous physical models, "crafted for their own ends, separated from the goal of a final design." (Morris, 2006:37), allowed students to explore how architecture conveys and/or supports feelings, attitudes and behaviors. This paper presents student explorations that combine models with annotations and drawings, demonstrating their value in exploring attitudes. Such models show spatial arrangements without a big investment of time, allowing spatial ideas to be quickly developed. Combining comparative models with annotations and drawings allowed for development of more detail and examination of design intentions, often generated unconsciously, to be made explicit. The exercise gave students an understanding of how the attitudes they were exploring could be manifest in design, thus permitting their pursuit consciously in later phases of the project. By pursuing two contrasting attitudes students came to understand how they could combine ideas to make more complex designs.

KEYWORDS

Youth; incarceration; trauma-informed care; sketch models; attitudes.

INTRODUCTION

In the United States a concern with mass incarceration, high rates of minority confinement, and in facilities for youth, has generated a national movement toward deinstitutionalization and inclusion of trauma-based treatment. There is increasing awareness internationally, that youth who get in trouble with the law often are subject to trauma in their home and community (Royal Australasian College of Physicians, 2011), and that facilities need to treat youth for this condition (Ford et al, 2006).
The research described here took place between 2018 and 2019 in the context of an architectural design studio that was jointly taught by Julia Robinson a university instructor, Daniel Treinen an architect in BWBR Architects, a firm that designs justice facilities for youth, and Angela Cousins, a government official in the local, Hennepin

County department of corrections who works with facilities for adjudicated juveniles. The purpose of the studio was to investigate new approaches to program and design of facilities that move away from older attitudes of punishment toward youth, and toward education, rehabilitation, transformation, and de-institutionalization. The studio, taught for two years with anticipation of at least one additional year, was conceived as a research-based course that engages in exploratory research as community-engaged scholarship (Robinson & Christenson, forthcoming). The first year it was taught, working with the corrections data, the class identified two neighborhoods from which most adjudicated youth in the juvenile facility originated. The subsequent year, the studio affiliated with the University Research and Outreach-engagement Center, a university neighborhood research center, and worked with community participants to understand, and design for the specific neighborhood context of North Minneapolis.

A central purpose of the studio was to understand how ideas, attitudes and behaviors represented in architecture can inform the design of youth facilities in support of healthy environments. Sketch models are described by Morris as "three-dimensional sketches , ideas made visible but not concluded in any way, They need not strain to arrive at a definitive model, but can be crafted for their own ends, separated from the goal of a final design." (Morris, 2006:37), They were chosen as a way to explore the relation between design and attitudes. These are accompanied with sketches and annotations that explore why and how the models are designed, addressing assumptions, hypotheses and design directives.

1. SKETCH MODELS AT THE UNIVERSITY OF MINNESOTA

The material architectural sketch model is an acknowledged form of investigation in architecture (e.g. Mills, 2005), but there is little scholarship around its use to study sensory ideas of materiality and relationship, rather than such concerns as structure and buildability. In contrast to the study model, or the digital sketch model, which represent an already-formed design idea, the content of the material sketch model emerges as it is constructed.

There is a history of the use of sketch models at the University of Minnesota School of Architecture. In the 1980s inspired by design instructor and phenomenologist, Gunter Dittmar, who introduced the Rip-N-Tear model to the school (Mulfinger, 1985), many colleagues began to use sketch models in a variety of ways (e.g. Weeks, 1985; Robinson 1990). Dittmar saw the sketch model, or Rip-N-Tear model as he named it, as a way to explore the phenomenological aspects of design. He assigned the models for their potential to suggest the ineffable, of the poetics of space. The ambiguity of the models allows designer and viewer to read many possible ideas into them, which interested other faculty to apply them in a variety of ways, even though Dittmar thought his colleagues used the models incorrectly.

Several faculty members used the models to explore narrative; for example, students might read a provocative story and design the place it evoked. Students would model and sketch the settings, using the narrative descriptions as the basis for a design. Other faculty members saw the possibility of annotating models and drawings to making implicit ideas conscious. For example, Dale Mulfinger (1985) and I (1990), have paired sketch models with annotations that encouraged students to identify elements in the model that could be used in design. In a studio with Stephen Weeks in the early 1980's

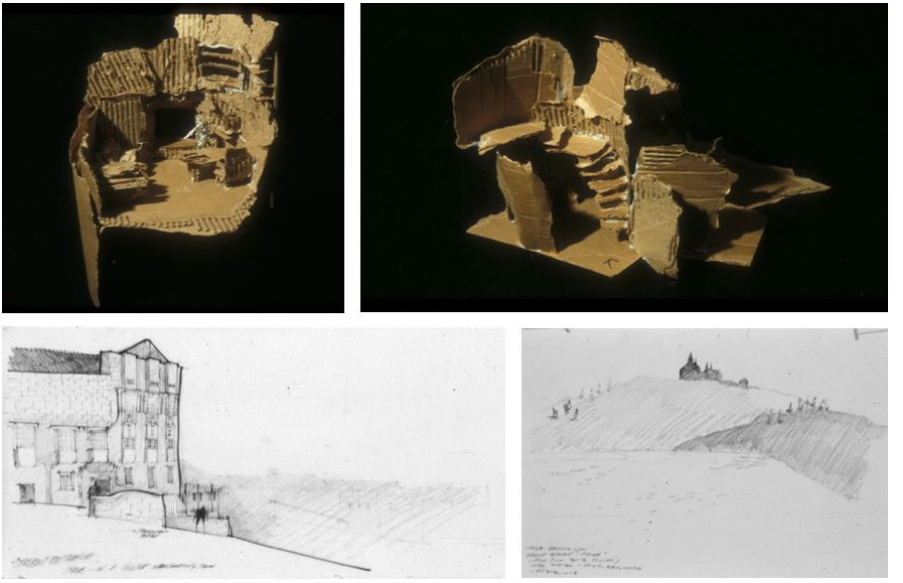

Figure 1. Sketch Models and Annotated Drawings Used to Explore Scholar Spaces at a Sherlock Holmes Library. Work by Julie Maple, 1988, Instructors, J. S Weeks and J. W. Robinson

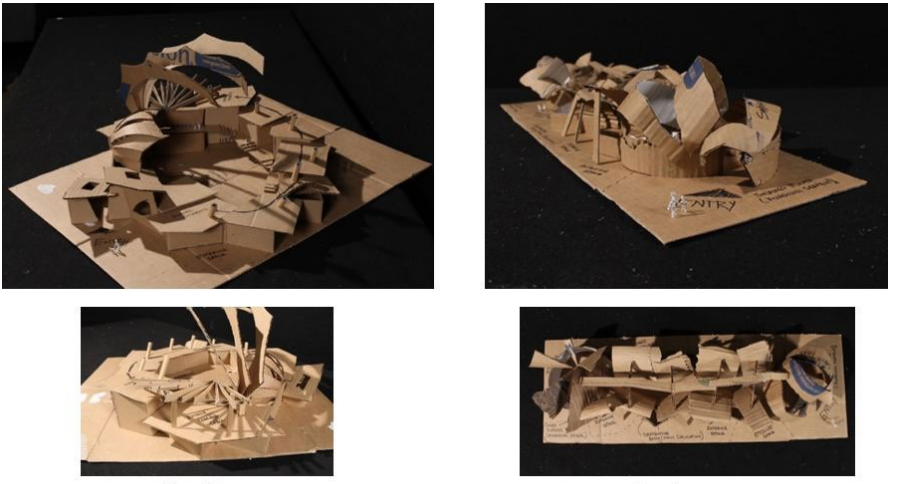

Figure 2. Sketch Models Showing Two Arrangements of a Waldorf School Developed Using Analogy (note annotations on the models). Mark Norberg for Arch 3282: Architectural Programming, Spring 2012, taught by the author

on the design of a Sherlock Homes library, he and I were interested in annotated drawings and had the students make sketch models as well as drawings that they annotated (see Illustration #1). Additionally, in studios with Dale Mulfinger and Lance LaVine we assigned sketch models along with drawings and annotations for several different exercises. Sketch models continued to be used by a variety of faculty as a teaching tool into the 1990's, and early 2000's, although recently their use is significantly reduced.

Nevertheless, I have continued to employ sketch models in my teaching as a way for students to examine the relation between ritual and place, and, often using analogy, to bring all the small explorations together to develop an overall design, using exercises from Programming as Design (Robinson & Weeks, 1984). Typically, the ritual-place exercises ask student to include scale figures in the model, to make annotations on the model, or to make sketches of their key findings and annotate the sketches. The exercises examining individual spaces are combined to make several optional spatial arrangements for the building. The annotations of the individual spaces and of the overall arrangements are used to make the ideas explored in the models explicit, so they can be consciously used in design. This is the approach taken in this research.

2. INVESTIGATING YOUTH INCARCERATION

In the fall of 2017, stimulated by Angela Davis's and Michelle Alexander's work on prisons and Jim Crow (Davis 2003; Alexander 2012), I decided to apply earlier research on de-institutionalization (Robinson, 2006) to incarceration. Being without funding or expertise on incarceration, but having made contact with other researchers working on the topic at the university, especially law professor, JaneAnn Murray, I saw an opportunity to begin research on the issues with students in design studio classes. The names of the classes show the evolution of research and understanding between the initial semester studying incarceration in general and the later studies about addressing youth: Reconceiving Incarceration (Spring 2018), Reconceiving Youth Incarceration (Fall 2018), Preventing Youth Incarceration (Fall 2019), Expanding Youth Opportunity (Fall 2020).

2.1. First Studio: Reconceiving Incarceration for Adults

I organized the first iteration of teaching by myself with advice from faculty members from the Law School and Public Affairs, as a 7-week vertical (for years one and two) graduate student design module that focused on adult incarceration. During the module, students visited a local adult correctional facility, completed assigned and discovered readings, watched videos on prisons and Jim Crow and solitary confinement, and engaged in discussions with invited speakers. The instructional approach included exercises on preconceptions, precedent analysis, ritual-place analysis, and schematic design development. The studio assignment was the design of a non-punitive prototype to be located an ideal site type of their choosing.

The sketch exercise was a central feature of the process of designing a non-punitive facility. It was seven days long, beginning in the third week of the seven week course. At this point in the research, several invited speakers had described their experiences 1) being incarcerated, 2) as parents of adjudicated youth 3) as lawyers working with the incarceration system, 4) as designers of youth facilities for incarceration or mental health, or 5) as workers in incarceration facilities. Several of these individuals also participated in reviews. The just-completed precedent analysis included innovative European sites for adult and youth offenders, as well as other institutional settings where non-incarcerated people live in (dormitories, nursing homes, summer camps, convents, monasteries, etc.). In consideration of such

Theraputic: Living Units
Units emphasize daylighting and connection to nature, containing expansive views and direct access to the outdoors. Cushy furniture, a bathtub, and personal artwork provide theraputic touches.

Individual Growth: Living Units
Units are customizable and furniture rearrangeable to individual tastes and are meant to teach residents how to take responsibility for maintaining their own living spaces.

Figure 3. Sketch Models Exploring Non-Punitive Attitudes for Incarcerated Adults. Design Module Spring 2018: Arch 5250: Reconceiving Incarceration taught by the author

precedents, the sketch exercise explored such attitudes as education, normalization, and therapy, some proposed by faculty others by students.

Students were asked to choose two contrasting attitudes to represent, and most took normative incarceration as one attitude and another attitude for contrast. The paired models and associated sketches and annotations led to design features the students employed (see Illustration 3), although the annotations were somewhat limited, and the level of insight was inconsistent across students, with some students identifying a number of specific features, and others providing more generalized conclusions. The graduate students understood the purpose of the exercise and used it effectively, including generating a final schematic design from the sketch models of the parts.

The guests at interim reviews included faculty from the law school and the institute for public affairs as well as several from the county department of corrections, including Angela Cousins from juvenile facilities, with whom I agreed to continue to research the following fall. The reviewers were especially fascinated by the explorations of alternative attitudes.

2.2. Second Studio: Reconceiving Juvenile Rehabilitation

The second iteration of the class was a 15-week design studio in which pre-professional undergraduates in their last year of study work with practicing architects. In most instances, practicing architects with teaching experience lead the students in a project that their office has completed or is working on. The studio is conceived as providing the opportunity for students to complete the design development of a project, providing experience with working drawings. In contrast, this project was research-oriented and both the practicing architect and the instructor from the county department of corrections were interested in understanding more about youth incarceration. The architect's firm designs facilities for adjudicated youth, and the department of corrections was interested in improving their youth facilities as well as developing a spectrum of care for youth.

Because we had fifteen weeks, we were able to visit more facilities, this time including the adult incarceration facility visited in iteration 1, but also the local site for youth offenders, and as an exemplary comparison, an architecturally notable addiction treatment

center for adolescents. Again, during the semester the students completed assigned readings, identified new important areas for research, watched the videos on incarceration, and heard guest speakers, but this time focusing on youth and including a psychiatrist who spoke on adolescent mental health. The instructional approach was similar, but with the extra time, included neighborhood and site analysis.

The two-week sketch models assignment took place in week four, right after the precedent analysis exercise and lasted two weeks, again exploring the themes of non-punitive design. Unfamiliar with sketch models, it took the undergraduate students a while to understand how they could reveal attitudes, and how to use drawings an annotations to document their learning. Some students grasped the idea (see Illustration), but others did somewhat impoverished models and drawings.

Once again students were encouraged to understand attitudes such as education, normalization and therapy. As before, they were asked to make paired models of a range of place types such as social spaces, eating places, circulation or corridors, sleeping areas, etc. Students used the models to explore different attitudes about spaces, but only loosely used pairing as a tool. Nevertheless, most students carried ideas identified at this stage into their final designs. We did not ask students to use their sketch model explorations to generate the overall design.

Subsequent to the sketch model study, students deepened their research, and in response to research specifically on adolescents, included consideration of trauma-based care. Additionally, students became concerned for institutionalized racism in response to our site visits, where we found that youth in the county facility housed exclusively youth of color, while the addiction treatment center housed 90% Caucasian youth. Statistics from the department of corrections showed that the youth in the county facility came almost exclusively from impoverished areas As a

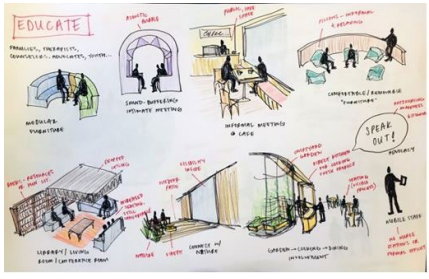

Figure 4. Model Exploring Entry & Annotated Drawings Identifying. Architectural Characteristics of Rehabilitation and Education for At-Risk Youth, Kelly Mork, Architecture 5212: Reconceiving Youth Incarceration, Fall 2018

result of these discoveries, the class decided that it was not appropriate to simply design better facilities, but that youth incarceration needed to be prevented. The county had suggested the class develop a spectrum of care for adolescents, but due to our findings, the group decided we needed to understand a spectrum of care for the families and the neighborhoods as well as youth. These discoveries led many students to consider designing places not just for youth, but also for families. At the end-of-semester review, the students suggested moving the sketch exercise to later in the semester when they had selected their program.

2.3. Studio 3: Preventing Juvenile Incarceration

Iteration three took place in fall of 2019. Because the previous studio had identified neighborhoods as being important contributors to the solution, this year -again working with architect Daniel Treinen and department of corrections juvenile representative, Angela Cousins- we decided it would be important to include community members in our research. The studio affiliated with the University of Minnesota's Robert J Jones University research and Outreach-Engagement Center on the city's Northside that was the site for a community meeting at the beginning of the semester and four additional reviews, These reviews included community participants who had been identified by a consultant recommended by the center and who received a stipend to work with us.

Like the previous year, the fall 2019 class engaged with readings and videos, visited the two incarceration facilities and the center for teen addiction, and heard from various experts. The class also toured the neighborhood and visited a neighborhood health center. Whereas previously the sketch exercise introduced the program, following the recommendation of the previous year's students, this semester we assigned the sketch exercise in week seven, after students had identified their program, as a way to explore the character of the facility. The exercise only lasted one week, which turned out to be more successful, as the

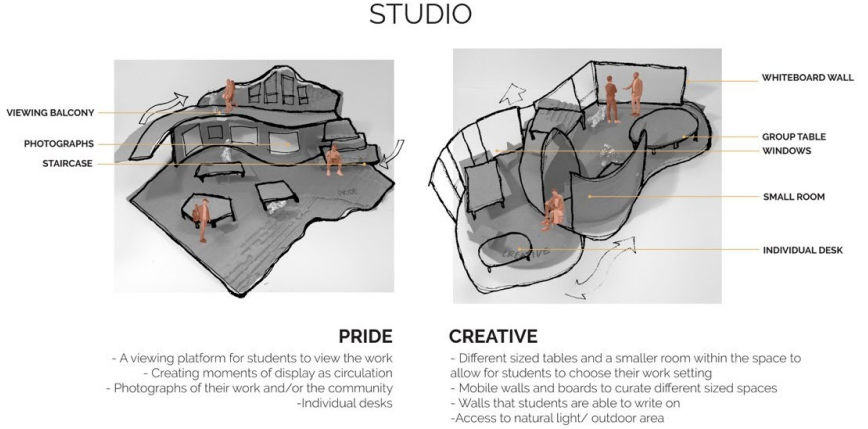

Figure 4. Paired Sketch Models Exploring Contrasting Attitudes for a Studio Space in a Residential Videography Job Education Facility, for Post- High School At-Risk Youth Maura McDaniels and Assia Rodriguez, Architecture 5212: Preventing Youth Incarceration, Fall 2019

students were motivated to explore spaces they knew were part of their design. Probably as a result of this improved understanding, the choice of attitudes transformed from being what one might call "building function-based," such as "education," "normalization"' and "therapy", to more specific terms, such as "curiosity," "transparency," "vulnerability," "security," "pride," and "creative" that captured the feelings they were trying to engender in their buildings. Again, students were asked to select contrasting terms to represent, and to feel free to represent apparent contradictions in the models.

As typical, on the first day of the assignment, students made a series of models in class and discussed everyone's models as the afternoon progressed. The big challenge the first day of the exercise was to choose contrasting terms that related to their projects. By the next class, once they had selected their contrasting ideas, they had successfully developed a series of contrasting models and fully understood the purpose of the exercise (see Illustration 4).

For the final day of the exercise they combined their paired models to create a sketch building layout. During this phase they were excited to discover that they could take the attitudes they had explored independently and combine them in various ways for different parts of their designs, this was especially interesting to those who at first thought their two ideas were oppositional. For example, the students who chose vulnerability and security realized if they could incorporate both attitudes in their spaces, it would allow more richness and choice to the people who would use them.

This time, we asked students to make a large model from their accumulated sketch models to represent their overall building design. This turned out to be very successful, and students developed a rich set of designs based on this exercise (see Illustration #5). This exercise was followed by a site exploration exercise in which students had to make 2 contrasting organizations and locate them on 3 different sites.

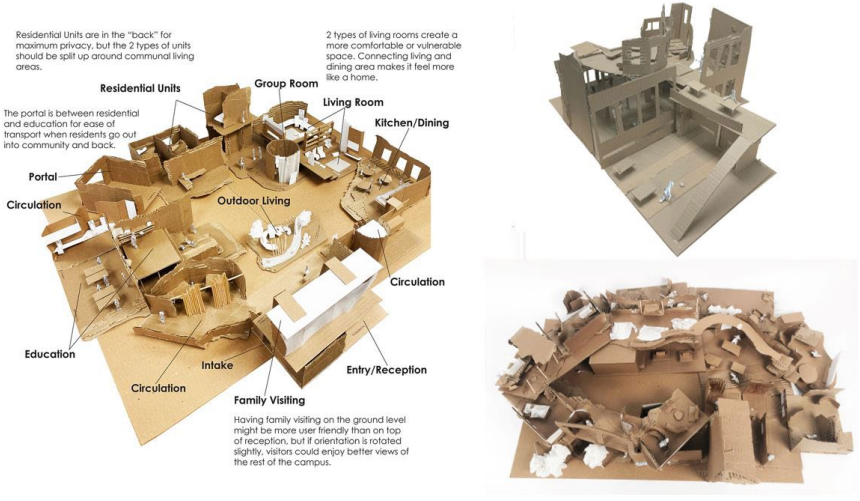

Figure 5. Combined Sketch Models Representing the Whole Building, one annotated Transition Residence by Jillian Gelle & Kristin Just, Neighborhood Youth Center by Angelo Davalos, and Videography Facility by Maura McDaniels & Assia Rodriguez, Arch 5212: Preventing Youth Incarceration, Fall 2019

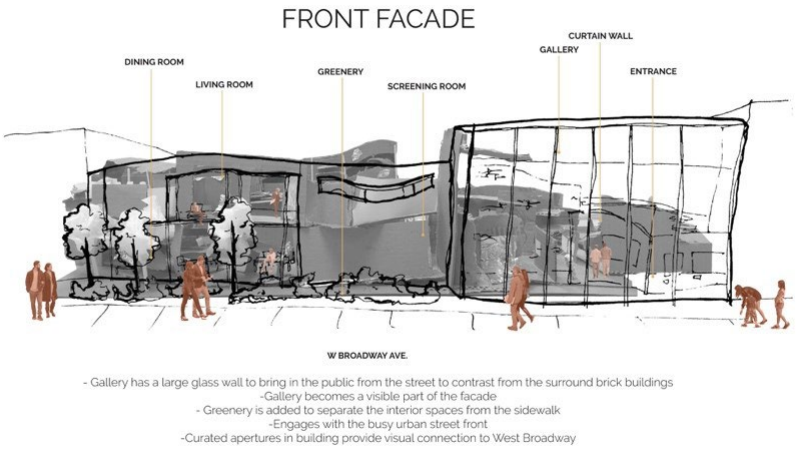

Figure 6. Annotated Model Photograph Used to Design a Façade A Residential Videography Job Education Facility, for Post- High School At-Risk Youth Maura McDaniels & Assia Rodriguez Architecture 5212, Fall 2019

This year as last, most students didn't annotate the models, and only some annotated associate drawings. But several of many of them annotated photographs of the models. And one group used their photos of the combined model to develop an interior courtyard and façade design (see Illustration 6).

The final projects for this third iteration exhibited a much better understanding of attitudes than previous classes. In the final course evaluations, one student commented "Exercises like the attitudes and rituals, with quick sketch and modeling were great! They were very helpful at visualizing the space as a design tool." Having changed the timing of the sketch exercise to later in the semester when students have chosen their program, they are in a better position to explore attitudes using sketch models.

CONCLUSION

Sketch models were chosen to explore attitudes because of their three-dimensionality, their ability to generate ideas in the process of making (as opposed to representing ideas already formed), their ambiguity that allows multiple readings, extending the imagination, and the ability to create many models quickly. By repeated use of the models over three years we discovered that the timing and pedagogical sequence of exercises significantly affected use of sketch models as a tool to explore attitudes. When we realized their best use was not as an introductory exercise, but as one to develop the architectural program, it more significantly influenced the schematic design.

At the first iteration, the graduate students seemed to be able to understand the purpose of the exercise from the beginning, and were pleased to explore the issues, although the

annotations were not as prolific as had been anticipated, and the attitudes were accepted as given, likely because of the placement in the semester. For this course, the students assimilated the ideas successfully, and the final projects reflected an understanding of how attitudes affect the design of places. For example, students were concerned to incorporate such ideas as choices in the way that residents of their facilities would inhabit their facility, sequencing activities to encourage engagement while assuring control, providing beautiful materials and comfortable furniture and locating facilities in a wooded area or incorporating natural light and plants in interior areas

The undergraduate students seemed to need more time and motivation to explore attitudes. The first year, they fully engaged in the exercise, accepting the attitudes they were given, but were not able to take the ideas as far as the previous year. Although originally, it seemed that sketch models would be a good exercise to introduce students to the challenge of designing with an understanding of how spatial configuration and arrangement affects people's attitudes and behaviors, this did not turn out to be true. At the beginning of a semester devoted to gaining an understanding of the importance of preventing incarceration, students have insufficient knowledge to know which attitudes are important, and why, and then to care about how to design using attitudes as a generative idea.

The sketch study exercises worked best when students had a greater understanding of the issues based on such information on readings, site visits, experts such as community members and had selected their program. Such knowledge enhances not only the comparative sketch model analysis exercise, but also the newly added combined model exercise so that it more effectively influenced the quality of the final design. When students understand and identify not only the qualities they are trying to embody, but also have criteria for generating and evaluating their designs, they can design with more nuance, more confidence and can achieve better outcomes.

PAPER #7.14

HERITAGE AS A RESOURCE, MEMORY AS A PROJECT. RESPONSIBLE NETWORK-BASED DESIGN STRATEGIES

Emilia Corradi[a], Alessando Raffa[a]
[a]Politecnico di Milano, Milan, Italy

ABSTRACT

The Italian territory is dotted with a large number of villages called Borghi Minori, that, for centuries, have represented the urban framework for vast territorial areas and identities inhabiting the landscape, now in a state of abandon. As part of an inter-disciplinary research on the fragility of the so-called 'minor' diffused heritage, this contribution responds to the present and future need to imagine new forms of living and transformation strategies for these abandoned settlements, through the creation of an operational methodology and the identification of specific tools. The selected urban areas are rooted in the territories of the internal areas of Abruzzo, interpreted as laboratory-villages, in which to experiment with innovative mapping processes able to deal with the complexity of these contexts. Here present fragilities become resources for imagining possible future scenarios, to be specified by the same Communities in an open and polyphonic transformation design vision. From an application point of view, this work resulted in the construction of a dynamic, multiscalar and interdisciplinary 'atlas of trans-form-actions', aimed at identifying in the stratified layers of the landscape palimpsest, those resilient and silent modifications that made these territories habitable. An atlas, a project sharing knowledge and information, which is characterized by a marked design dimension. Here the transformative processes of the landscape are interpreted as a continuous sequence between past, present and future. Topographies of memory whose feature is a non-hierarchical network, made up of layers and rarefactions, which becomes the framework for the trans-form-action, in which design actions correspond to spatial devices, whose architectural expression will derive from present and future needs, a sharing path, listening places and people.

KEYWORDS

Minor diffused heritage; transformation; weakness; abandonment; reuse.

THE WEAK COSTELLATION OF BORGHI MINORI D'ABRUZZO. AN INTRODUCTION

The Italian territory has among its peculiarities that of being dotted with a large number of small villages, the Borghi Minori, that have been suffering for decades due to depopulation, causing different abandonment conditions over time. About 6,000 villages (Istat 2014), with a prevalent distribution in central and southern Italy along the Apennines but also in Alpine areas, were abandoned over time for various traumatic reasons, such as earthquakes, hydrogeological instability, epidemics, wars and, in the years of the post-war economic boom, the rural exodus in favor of concentrated urbanization; finally, more recently, owing to the demographic decline. The Borghi Minori, in fact, are only the "tip of the iceberg" of a widespread and complex process of abandonment that involves the internal areas and that has determined a turning point, apparently not reversible, in the contemporary Italian settlement dynamics. As shown in the 'Geography mapping of

abandonment. The dismissal of the villages in Italy' (Postiglione 2006), it is possible to identify three characterizing conditions: completely abandoned villages, those partially abandoned and those in abandonment but with a newly founded neighboring center. With respect to this categorization, which intentionally reduces the complexity of the abandonment processes to bring the phenomenon to a national scale, the present research has looked at the second condition, the most widespread one. It has considered those villages that have never suffered a complete dissolution, in which the abandonment 'process' is taking place today. Economically depressed for decades, these villages are often isolated, difficult to reach, inadequate to contemporary living standards and characterized by a certain instability due to cataclysms. Villages in which the surviving communities, custodians of a material and immaterial heritage, seek forms of adaptation to the disappearance of a socio-economic-cultural reality that obviously cannot return. We will look at a specific context, that of the internal areas of Abruzzo, in which the phenomenon described above, in particular when connected to the effects of an often violent seismic activity, generated a landscape of widespread abandonment, but where, at different times, possible strategies were tested and design solutions adopted to respond to the need to inhabit the constellation of Borghi Minori that characterize this landscape. For centuries these villages were the most frequent urban settlement model in Italy and the expression of specific and resilient ways of inhabiting the territory. Today these villages reveal their yielding fragility, and, despite the interest shown by parts of the scientific community and civil society, the experiments carried out reveal working methods and tools often inadequate to the complexity of those contexts. Here the heritage dimension is 'minor', that is, not made up of exceptional elements. The value lies in the relationship between the parts, at different scales, from the territory to the 'room'. This non-hierarchical and layered network, made up of very different and minute elements, but nonetheless important, is rather foundational in the process of building and modifying the landscape identity. These elements are fragile, since they are often unknown, not registered and also, sometimes forgotten, and for this reason often distant from protection mechanisms that could take them into the present and in the future, if included within enhancing processes through a responsible transformation. The transformation project for these villages requires new looks, methods and tools capable of managing the complexity that these realities require. In an interdisciplinary vision open to various stakeholders, the architectural discipline and its project become a shared place for confrontation, to imagine new scenarios of responsible reuse for the Borghi Minori landscape.

1. RESEARCH OBJECTIVES

This work is part of an ongoing research by the Department of Architecture and Urban Studies[1], Department of Excellence, on the issues of territorial fragility. Its objective, among others, is to highlight issues, identify work methods and tools for the strategical design of the minor diffused heritage, recognized as one of the central themes to promote the future quality of the territory and characterizing contemporary cities in Italy. In this framework, the present research looks at the constellation of abandoned Borghi Minori, imagining interdisciplinary and shared reuse strategies to address today's needs. The present research has two main objectives:

• From a methodological-operational point of view, it intends to identify a working method

[1] Students and graduates from the Bachelor and Master degree programs from the School of Architecture Urban Planning Construction Engineering, Politecnico di Milano, also collaborated in the research project: Abagnale, R., Ambrosi, A., Airoldi, F., Ballarani, G., Camboni, J., Finardi, R., Forcignanò, R., Miranda, M., Montisano, M., Santus, A., Sartorio, S., Scaioli, A., Tolazzi, S. and You, Z.

and tools for the 'open' project of transforming abandoned urban settlements, by means of a continuous exchange between theory and practice mediated by the design process. Method and tools will be tested on a selection of villages characterized by different semi-abandonment conditions and located in the internal areas of Abruzzo. A taxonomy including research and project experiences has become necessary, in order to compare methods and tools, bringing out potential and critical issues.

• From an application point of view, the research intends to build a dynamic and multidisciplinary atlas of the trans-form-actions for the smaller villages of Abruzzo, to highlight the dynamism of the stratifications with particular reference to the most recurrent forms of fragility in the internal areas. The atlas is designed to offer both a reading of the transformations of resources over time, with forms of fragility and resilience, and an operational tool, capable of updating future research, processes and projects that will involve the identified areas.

2. SEARCHING FOR AN OPERATIONAL METHODOLOGY

2.1. Mapping researches and projects on Borghi Minori. State of the art

In the context of the design disciplines, the topic of abandonment and reuse of the Borghi Minori has been the subject of multiple reflections and experiments with the most varied outcomes. In a previously mentioned research work, '*Geographies of abandonment. The dismissal of the villages in Italy'*, (Postiglione 2006),), in addition to restoring the national and international scope of the theme, a taxonomy of projects for the reuse of those villages is systematized. Among the experiences mentioned: the 'cybervillage' of Colletta di Castelbianco, designed by Giancarlo de Carlo; the idea of a 'widespread factory', with which the industrialist Brunello Cucinelli rethought Solomeo (PG); the 'diffuse hotel model' of Santo Stefano di Sextantio, which will be replicated in other villages purchased by the entrepreneur-architect Daniele Khilgren. These are widespread strategies, yet limited to the reuse of the built-space. Starting from an examination of the existing literature and from design experiences on abandoned villages, work methodologies and approaches were compared, in order to bring out potential and critical issues. In this theoretical-critical framework, an orientation towards the reuse of built heritage emerges, not fully grasping their regenerative potential. Recently, the research experience of the University of Chieti, summarized in the essay *The region of the major highlands of Abruzzo* (Angrilli and Morrica, 2017) widens the scope, not only to the built heritage but also to the open space in relation to the villages, identifying, in particular, the "proximity landscape". This space is defined as a "transition space between urban formations and the open wooden-agro-pastoral space" and indicated by the authors as "strategic for territorial recycling objectives." (Angrilli and Morrica 2017, 37). The present research takes a further step forward in this direction, through an 'ecological' perspective on the theme of the Borghi Minori, and more generally on the diffused 'minor heritage'. The villages, if we consider the territorial structure of the internal areas, in fact, are nothing more than urban densities compared to a vast network of places, areas, artefacts and materials, expression of the adaptability of the communities to the surrounding environment over time.

The obsolescence process that affected them is actually more extensive, it concerns the entire territory; its profound reasons can only be understood through a relational approach in order to frame them in dynamic processes that consider space, time and the communities that inhabit them. For these reasons, we have looked at the 'minor heritage' as a 'minor heritage landscape'; a landscape, therefore a place of sedimentation of processes, an expression of the interaction between the

Figure 1. Multi-space and multi-temporal layering reading of the abandoned village of Navelli. Source: (Corradi, E., Raffa, A., Santus, K., Sartorio, S., and Scaioli, A. 2020).

environment and the communities that have shaped the territory for their own subsistence, in a resilient way, adapting to an impervious nature, to the inaccessibility of places and to traumatic events. A fragile landscape, made up of very different identity elements, in terms of morphology, materials, scales, etc., which slowly loses its most minute elements, progressively compromising its specificity.

2.2. A historical ecology perspective on minor heritage landscape. Theoretical framework

In the broad vision that this research adopts, from the village to the landscape to which it is rooted, from a theoretical-critical point of view, an element of innovation regards the opportunities, currently unexpressed, for the design disciplines that operate on the heritage landscape, which could arise from the intersection with the theoretical contribution of Historical Ecology (Balée 1998; Baleé and Erickson, 2005; Crumley 1994, 2012) for a modification-oriented knowledge. Starting from the idea of *longue durée* (Braudel 1958) and palimpsest (Corboz 1985), the landscape is interpreted as the provisional and stratified result of the interaction between man in his social dimension, the community, and nature. Historical Ecology proposes the overcoming of the division between anthropic and natural through the emphasis placed

on the process of trans-form-action on the landscape; certainly a lengthy process, but made up of numerous 'critical moments', which are contextualized in a dynamic frame in space and time, breaking down reductive schemes. Furthermore, historical-ecological approaches are multi-disciplinary (linking archeology, history, geography, ecology, design, etc.), multi-scalar (moving from macro to micro processes) and multi-oriented (researchers, stakeholders, managers and designers) (Crumley and others, 2017). In this perspective, it was decided to look at the landscape in terms of fragility. The intent was to investigate the generative processes of present fragility in a dynamic way, as the unstable result of secular interactions between man and the environment, which produced the current geography of fragility in the internal areas of Abruzzo. These fragilities have redemption possibilities, often turning into possible resources. Within the dialectic established between fragility and resources, a greater awareness of the fragile processes that have affected the areas in question, together with the forms of adaptation put in place, constitute a source of important information for projective knowledge. Past forms of resilience, combined with current innovation, can generate processes capable of facing contemporary challenges, acting local while thinking global. Through a topographical criterion it was possible to intersect various conditions of fragility linked to four key resources: soil, water, infrastructure and built-heritage.

2.3. Methodology

The methodological construction of an experimental nature intends to structure an open project, in order to welcome complexity, substantiated by "an ethic of interconnection and solidarity between humans". (Morin 2010). This experimentation of a methodological-operational nature will be better specified and verified in the future through comparison with other contexts. Within this perspective, the architectural project, understood in a broad way, plays a strategic and structuring role, capable, at the same time, of welcoming a wealth of specific visions and projects, even at different times, affirming its positioning as a listening and confrontation platform oriented towards transformation, in an interdisciplinary way.

The listening of people, groups, associations and communities, conducted on the occasion of workshops and visits to the pilot villages, was essential both to delve into a complex reality and, above all, to understand the future scenarios that those who live and care for places imagine. A highly resilient social structure, albeit numerically small, in which an attempt has been made to engage in dialogue starting from the relationship established with the minor heritage spread locally today. Therefore, an attempt to develop a 'synthetic form' was aimed at harmonizing the listening of groups and communities, their needs and to offer a framework to their planning potential, together with the scientific interpretation of local fragilities; but also at 'dissolving' the contemporary complexity of the landscape of minor villages, through the decomposition of the different contexts through specific themes, an expression of the multiplicity of visions that characterized this research experience. The resulting mapping process required extensive reflection, not only regarding the tools to be adopted but also for sharing them, in an open critical perspective, raising problems and revealing opportunities over time, in a continuous polyphonic dialogue between listeners and narrators.

The application output, that is the dynamic atlas of the villages, is a selection of interpretative maps of fragilities, among those possible. It is an expression of the dialogue between researchers, groups and communities of the four selected villages. The atlas collects mappings at different scales and also describes the Borghi Minori networks, made up by points, lines and fields, all susceptible to transformation. With respect to these areas, an abacus of architectural

actions associated with spatial devices has been finalized and will be better specified over time, starting from the needs of the locals.

2.4. Mapping as a project. The design-oriented dynamic Atlas of Borghi Minori's landscape

The synthesis maps express the multidisciplinary approach adopted. These are qualitative but also quantitative elaborations, at different scales, of both material resources (infrastructure, nature, cultural heritage, soil, energy, etc.) and intangible (such as culture and traditional knowledge), the latter investigated through multi-criteria indicators. The in-depth resources have been dynamically linked to each other, both with regard to past transformations and the development scenarios, however uncertain, that will be introduced in internal areas by global changes (in particular climatic and pandemic), in line with the open planning perspective that this work supports.

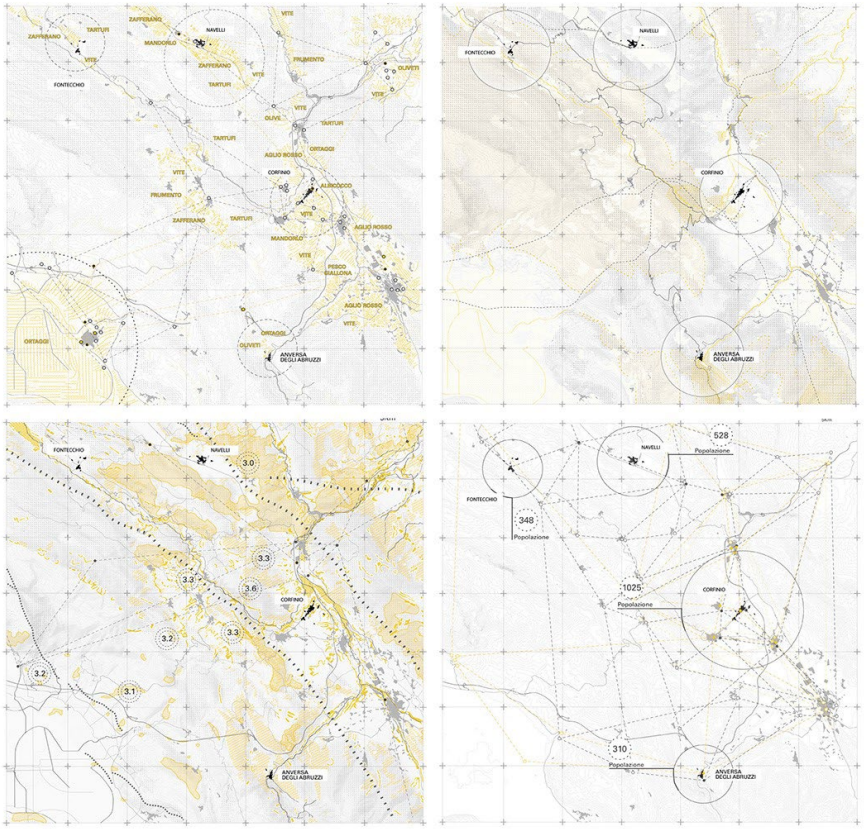

Figure 2. Maps of the Borghi Minori Network between Anversa degli Abruzzi, Corfinio, Fontecchio and Naveli. Traditional cropping infrastructure (top left corner); natural infrastructure (top right corner), tourism infrastructure (bottom right corner) and risk network (bottom left corner). Elaboration from the dynamic atlas. (PI Corradi, E., with: Raffa, A., Santus, K., Sartorio, S., and Scaioli, A. 2020).

The extension of the field of investigation, from the village to the system of relationships that deeply root the village in its context, called for appropriate tools capable of supporting a broad process / project of investigation of fragilities / resources.[2] The fragility mapping process, which took advantage of GIS technology and three-dimensional models, responds to the following needs:

- Interpreting materials and their specific fragilities in space and time, in a dynamic way, building a geography of fragility;
- Managing and communicating a large amount of data, interdisciplinary, multi-scalar and aimed at different targets (from researchers, administrations, citizens, etc.) and their implementation over time;
- Defining a non-hierarchical and operational network, a synthetic shape, which will frame specific future interventions.
- Guiding future transformations through an architectural abacus, which defines spatial devices, to be specified by future projects.

From an application point of view, the data collected were merged into an atlas of the Borghi Minori's fragile landscape. The atlas, like any form of cartographic representation, is interpretative and, in particular, is oriented to update and support future transformation processes. Furthermore, its dynamism allows continuous updating and monitoring, in order to direct the interventions according to a general and detailed vision. The aim was to conceive the construction of a dynamic multidisciplinary atlas, able to include different kinds of information, also non-topographical, over time. Furthermore, the atlas is configured as an interactive tool for researchers, administrators and professionals responsible for managing the territory, but also for civil society in order to build shared narratives.

2.5. Dynamic Network-based strategy and the architectural abacus

An operative topography of fragilities was thus outlined, a topography of memory, and therefore a project. The historical ecology approach to landscape, which allows to relate very close and distant times, spaces and visions, is based on listening to traces and their connection to present and future, welcoming the prefigurative and design-oriented dimension. The identified bio-cultural resources and the related forms of fragility were mapped together in the four selected laboratory villages - Anversa degli Abruzzi, Corfinio, Fontecchio, Navelli – revealing an operational topography in which the main feature is the network. Not a top-down network, a network originating from the intersection or coexistence of multi-temporal traces and contemporary needs of the inhabitants. A network with a high regenerative power for the Minor Villages, its peculiarities are capable of addressing in an integrated way the responsible reuse actions to the respective centers. Each of the four selected villages has its own peculiarities, which have been evaluated in order to predict possible shared futures. The interpretations outlined have been verified on the field, also through meeting occasions with the local communities and associations that brought out the daily vulnerability of an impoverished social context, but also the need for listening and dialogue; this also had an impact on the methodological construction.

From a polyphonic and open project perspective, that was considered to be pursued in light of the analysis of experiences "from above" as well as those that arose "from below", this network becomes a multi-scalar, territorial and urban framework, which defines nodes (existing elements that are involved in the strategy or new spatial devices), axis (existing connections redefined or new, elements with strong directionality) and fields

[2] The proposed approach to mapping refers to the epistemology of complexity and transdisciplinary (Morin 2001; Nicolescu 2002).

(significant areas re-signified by defining the edges) of a non-hierarchical network, made up of densifications and rarefactions, within which to identify architectural devices connected to specific design actions, through an abacus of solutions that other authors will be called to define over time (Di Franco et al., 2018).

2.6. Tools for an architectural reinvention in the Borghi Minori Network

It is clear that the set of theoretical and operational tools need to establish a defined, measurable, replicable range of actions. To define boundaries, networks, spatial and visual relationships, morphological sequences and connections to which conditions of fragility and interpretative potential are often linked, it is necessary to understand the new territorial vocation. Starting from instances and bottom-up actions - as already encountered in some internal areas- the difficulties deriving from depopulation, abandonment, and decommissioning find new revitalization scenarios through the rediscovery of the minor heritage of landscape and villages. Projects and processes in which the landscape is restored with new values and which, in turn, become maintenance strategies for the affected areas. An operating practice aimed at the recovery of artefacts and systems. The pathways, the small rural architectures linked to fields and pastures with their organization borrowed from former production cycles, increasingly find the attention of small, yet very active, communities, in which the search for life models closer to nature leads to rediscover alternative ways for production, such as the recovery of crops, techniques for sustainable land exploitation and farming. A rediscovery of artisan production cycles in which products aspire to becoming an excellence through the acquisition of values inspired by sustainability. In this experimental dimension, architecture can certainly intervene on both material and immaterial infrastructural networks, in order to guarantee a process of sustainability and sensitive insertion within contexts; neither mimetic nor vernacular, but suitable for expressing expectations, vocations and forms of living different from strong contexts, such as urban areas. An adaptation to the usage needs that fuses comfort together with technological performances, in which the digitization and access to global network resources is an important opportunity, often denied to people in these areas by market logics that act on much larger numbers of users. Building networks, even immaterial ones, can be a way of guaranteeing access to knowledge in these contexts, and if an opening process is also linked to the differentiated accessibility for users who are not only occasional, but stable because they can move and operate in contexts without constraints and physical barriers, it can be an opportunity to relaunch internal areas and smaller villages (Corradi, 2016). Architectural design can therefore become an element of coherence facilitation among different scales and heterogeneous objects and artefacts. Infrastructures, fields, houses, squares are all elements that converge to define how to use space. Different and new needs deriving from different instances and vocations need to be able to redeem these contexts also through simple operations, capable of combining on a small scale artifacts, and on a large scale, infrastructure networks, landscapes, cultivated fields, pastures, springs etc. Among the most interesting operations observed working in this direction, that emerged from the ongoing research, are those related to the architectural recovery of historical settlements such as in Fontecchio (Aq), a small town in the Abruzzo Apennines heavily damaged by the 2009 earthquake, where interventions for social housing were carried out, as well as small-scale social housing in smaller contexts, addressed for example to young families in urban areas with difficulties

in accessing the real estate market owing to their economic fragility.
This also requires innovative architectural design tools to hold together an existing heritage, which is fragile due to age, construction techniques, safety standards, technological and energy adaptation. An innovation project in which research by design can express replicable and transmissible methodologies, applying a scientific process to architecture. This also belongs to the strategies that architecture can implement to determine new topographies starting from the recognition of the value of heritage closely linked to landscape and to the context.

OPEN CONCLUSIONS

The experimentation, which is still ongoing, opens up to the identification of a possible operative methodology for the transformation project of the Borghi Minori. An approach that renews the consolidated methods of intervention towards this peculiar minor diffused heritage - essentially oriented towards the recovery of buildings - which does not lose the regenerative potential of a multi-spatial and multi-temporal relational gaze. The knowledge of the landscape's long-term processes that had produced different conditions of fragility and the needs and future possibilities envisioned by communities and groups together had been seen as an opportunity for responsible transformation. A topography of fragility which is a topography of the memory, a strong projection to the future. Furthermore, at the same time, it allows monitoring, continuously implementable, of changes accelerated by the effects of catastrophic events, as well as those also induced by global changes. An abacus of architectural devices, which correspond to specific actions, are based on this evolving multi-scalar network, which other authors will be called to specify according to present and future needs. Each transformation project finds meaning within the network and at the same time transforms it, in a process that continues the contemporary rewriting of the landscape, capable of opening unpredictable scenarios in the future. At the same time, the planning methods envisaged by the program incorporate the time variable themselves; the architectural devices show different degrees of permanence, oscillating between emergence and structurality. It was in fact decided, coherently with the type of dynamic readings of the Atlas, to imagine a project not only with several voices but also with several times, in which the architectural devices of the abacus can become pieces of an asynchronous assembly, in a continuous exchange between community and landscape, both realities in continuous transformation. The three methodological step listening, reading and designing are people-centred and interpreted dynamically. The Atlas, understood both as a form of knowledge and as a process/project, becomes an instrument for shared planning between researchers, designers, stakeholders and communities that will intervene in these places over time. In this context, the issue of abandonment is recontextualised with respect to a juxtaposition of other conditions of fragility, also social; the answers identified by the design experiments conducted in the specific contexts of the chosen Borghi Minori will manage to respond in a more founded way, both to local needs as well as to global themes. The open and polyphonic process/project is crucial for the replicability of the operational methodology: the landscape approach informs people-based heritage-centred cultural significance processes, both in the analytical and design phases. Here the architectural discipline, and its project, become a shared space for a heuristic dialogue between different disciplines, all collaborating for envisioning new scenarios of responsible reuse of the Borghi Minori's landscape.

PAPER #7.15

DAYLIGHTING AND ELECTRIC LIGHTING POE STUDY OF A LEED GOLD CERTIFIED OFFICE BUILDING

Jae Yong Suk[a], Antonio Martinez-Molina[a], Hazem Rashed-Ali[a]
[a] The University of Texas at San Antonio, San Antonio, TX

ABSTRACT

Integrated daylighting harvesting and electric lighting system is a key strategy to maximize energy saving and improve occupant comfort and productivity in buildings. However, providing desired amount of light and outdoor views to occupants without causing visual discomfort has been challenging in practice. Located in IECC Zone 6A, the design of a selected LEED Gold certified office building was driven by environmental performance. The building houses a mix of open/closed office spaces, laboratories, conference rooms, and cafeteria in 90,839 sf floor area. Among a number of sustainable features, the fully glazed facades and automated daylight harvesting systems play a critical role in providing daylight in 77% of regularly occupied spaces and direct outdoor views in 91% of the spaces. The building is equipped with automated roller shading systems controlled by a sun tracker mounted on the roof. Electric lighting in open office spaces are automatically controlled by the pre-determined control algorithm. The paper presents a thorough investigation of lighting quality and quantity of the building by adopting a research method combining subjective occupant survey and field measurements. Online surveys were first conducted to reveal any visual discomfort, outdoor views, or privacy issues experienced by the occupants. Various light sensors were utilized to measure daylighting and electric lighting performance throughout the building. Various lighting parameters including illuminance, correlated color temperature, and color rendering index were recorded. Luminance distributions were also documented by high dynamic range imaging technique and the lighting scenes captured in HDR format was analyzed by Daylight Glare Probability metric to evaluate various discomfort glare sensations. The survey results and the field measured lighting parameters were thoroughly compared and analyzed so that findings from this study can help develop a framework for evaluating daylighting design performance in built projects.

KEYWORDS

Daylighting; electric lighting; post-occupancy evaluation; occupant comfort; LEED.

INTRODUCTION

Energy efficient architectural lighting systems and daylighting design strategy can save building energy consumption and also improve occupant comfort, health, and productivity in buildings. As visual comfort and visual interest become critical for occupant well-being, direct view of exterior environments and sufficient exposure to natural light are greatly encouraged by sustainable architecture design guidelines. However, it has been challenging to provide direct views to outdoor while ensuring visual comfort due to the nature of consistently changing natural light environments. A thoroughly coordinated electrical lighting and daylighting design can still fail when they are not effectively controlled. Occupants in the buildings with many sustainable design features can still

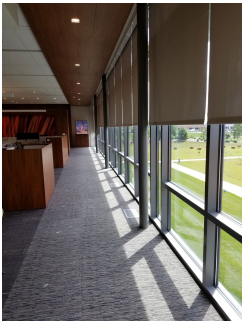
experience visual and thermal discomfort caused by sunlight penetrations, excessive or insufficient light intensity, or high contrast between workstation and surroundings (Hirning et al., 2013 and 2014; Suk and Schiler, 2012; Suk et al., 2013; Konis, 2013). Therefore, it is crucial to conduct a post-occupancy evaluation study particularly in LEED or other sustainability certified buildings in order to learn from their success and failure.

Recently, post-occupancy evaluation studies are increasingly performed by leading private architecture/engineering firms, federal government agencies, and academic researchers (Choi et al., 2019; Nicol et al., 2016; Fowler et al., 2011; Katzenstein, 2013; Hirning et al., 2013; Suk and Schiler, 2012; Suk et al., 2013; Konis, 2013). These efforts help design professionals to be able to match predicted design performance to actual occupant experiences. However, conventional lighting and daylighting POE studies still focus on either subjective responses of occupants or a few illuminance measurements. This incomplete or overly simplified study method can make design professionals to misinterpret whole building performance due to the limited amount of data. Therefore, it is critical to obtain both qualified and quantified data sets to fully understand how sustainable design features impact occupant experiences and comfort in a building.

1. BACKGROUND

The selected case study is located in Fond du Lac, Wisconsin. Located in IECC Climate Zone 6A which is classified as cold climate, the building was completed in 2017 and LEED Gold certified. The building has two floor in 83,402 sf gross floor area and also includes an open courtyard which is in 7,441 sf (Figure 1a). The project houses a mix of open offices, closed offices, laboratories, conference rooms, meeting rooms, cafeteria, etc. in four wing configurations facing each of the true orientations. Among a number of sustainable features, floor to ceiling side lighting and sophisticated daylight harvesting systems play a critical role in providing occupants 91% of direct line of sight to outdoor views while providing sufficient but comfortable light levels at workstations. The daylight harvesting system utilizes exterior louvers, a sun tracker on top of the roof, daylight sensors mounted on ceiling, and automated fabric roller shades along the glass facades (Figure 1b). With seamless communications between these elements, the project achieves 77% of regularly occupied spaces with sufficient daylight (sDA300/50%) which also helps to lower building energy consumption.

a)Exterior view of the building (view from South)



b)Open office

Figure 1. a) Exterior view of the building (source: Overland Partners) and b) automated roller shades at open office

As excessive sunlight penetrations can cause occupant visual discomfort, the interior roller shades are automatically adjusted depending on solar positions and sky conditions. While shading devices are adjusted, electrical lighting fixtures are also automatically controlled to adjust light outputs so that desired illuminance level of 300 lux is maintained at workstations. Since the building is configured with four rectangular wings facing different orientations, it is possible to predict lower sun angles in the two wings facing East and West orientations in the morning and afternoon. Because of different sun angles introduced in each of the wings, each wing is individually controlled to adjust its shading and lighting. This daylight harvesting system ensures visual comfort and direct outdoor views in open and closed offices. Open offices in the four different wings are around 12.2 m (40.0 ft) deep from windows with the ceiling heights varying from 3.3 m (10.7 ft) to 3.6m (11.7 ft) A.F.F.

2. METHODOLOGY

In order to accurately evaluate lighting and daylighting performance of the project, both online based occupant survey and quantified data collection techniques were utilized as follows. Online survey questionnaires were sent to the building occupants prior to scheduled field measurements. Two weeks later, two day site visit was performed to collect quantified lighting data including illuminance, correlated color temperature (CCT), color rendering index (CRI), and luminance distribution throughout the building during normal office hours on August 13th and 14th, 2019. During the field measurements, the building was in a normal operation so that the collected data should represent actual lighting conditions experienced by the users. For example, electrical lighting and shading devices were automatically controlled during the field measurements. Various lighting data collection tools were utilized such as illuminance meter, spectrometer, luminance meter, and DSLR camera.

2.1. Occupant Surveys

Online based occupant surveys were conducted first to understand any problematic issues related to lighting and daylighting in the building. The survey results were analyzed to see if there is any specific areas of concern to occupants. Demographic summary is as follows. A total of 123 occupants participated in the survey (45 male, 74 female, 4 not identified). Majority of the participants (88.6%) are in the age ranging 25 years to 64 years old. 72.7% of the participants have worked in the building longer than 2 years. Besides the general demographic questions, the following lighting focused questions were asked to each participant. A few selected sample questions are presented below.

• The primary source of lighting in my workplace: natural light, electric light, both

• On a clear or overcast day, the light in my workspace is: often too bright, neural, often too dark

• How satisfied / comfortable are you with the amount of light in your workspace?

• If you experienced visual discomfort, how would you rank the problem?: perceptible, disturbing, intolerable.

2.2. Measurement #1: Illuminance, Correlated Color Temperature, and Color Rendering Index

A spectrometer was used to record illuminance levels, CCT, and CRI in various spaces of the building. Horizontal illuminance levels were measured at various heights depending on primary visual tasks required in each of the spaces. For example,

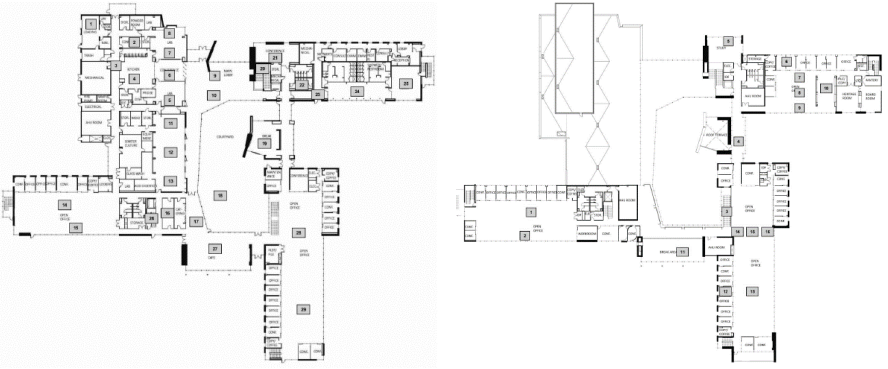
illuminance levels were measured on the finished floor levels in circulation spaces. In office spaces, illuminance levels were measured on top of a desk. The spectrometer measured and presented all three lighting parameters (illuminance, CCT, CRI) in each measurement. Figure 2 shows the locations of the measurements in each floor. The measurement covered both primarily daylit areas and non-daylit areas of the building and was repeated multiple times during the office hours from 8:00AM to 5:00PM. Outdoor illuminance levels, CCT, and CRI data was also collected to understand exterior luminous conditions while indoor lighting data was collected. A total of 29 different locations were measured throughout the first floor and a total of 16 locations were measured on the second floor (Figure 2).

2.3. Measurement #2: Luminance Documentation (HDR Photography)

HDR imaging technique was utilized to capture interior luminance distributions. Even though the survey results reported that there is little concern of visual discomfort in the building, HDR photography was still performed to validate the positive responses from the participants. A manual DSLR camera and tripod was set up at different locations. A total of 11 full-stop exposures (±5 exposures and normal exposure) were taken for each HDR photography. Each HDR photography was made solely by shutter speed adjustments without changing aperture values. The captured low dynamic range images were then combined to create a HDR image in Photosphere software. A total of 26 HDR photographs were taken at 26 locations in a perspective field of view in order to map luminance distributions. Another set of 9 HDR pictures were taken at 9 different locations in an angular fisheye view for visual discomfort analysis purpose. The 9 pictures in angular fisheye view were then processed in Photosphere software to calculate Daylight Glare Probability (DGP) scores. The camera and lens combinations were calibrated in Photosphere software with measured luminance values on a grey board prior to the study.

3. ANALYSIS

As stated above, occupant surveys were statistically analyzed first to identify potential problems of the building. And, field measurements were thoroughly made throughout the building. The field measured



a) 1st floor

b) 2nd floor

Figure 2. Lighting measurement locations

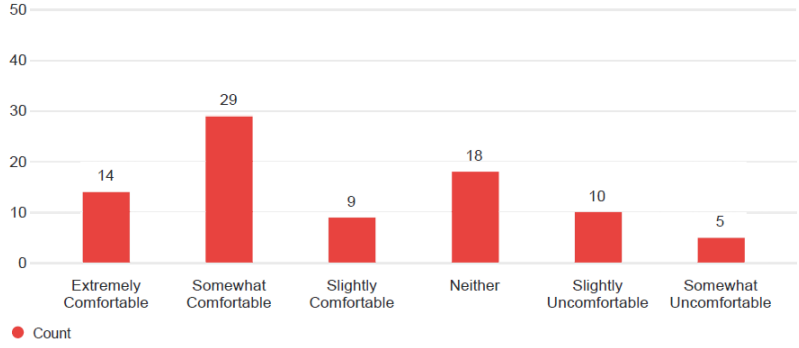
data was processed to be compared with the various lighting and daylighting design guidelines such as Illuminating Engineering Society (IES) and General Service Administration (GSA) P100.

3.1. Occupant Survey Results

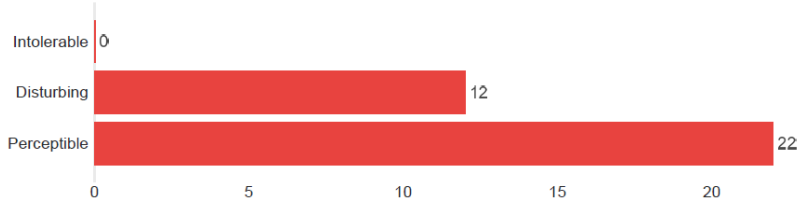
With the large side windows in most of open and private offices, 89.1% of the participants (a total of 110 responses) reported that they have natural light in their workspaces. 76.4% of the participants also reported that they have a good amount of light in clear/sunny day while 88.2% of them feels that lighting is appropriate in cloudy/overcast day. Only small percentage of the participants reported that it is either too bright or too dark at their workstations. While answering to the survey questionnaires, the participants also wrote comments regarding lighting and daylighting. Figure 3 displays the most often mentioned lighting related terminology from participants' written comments. Larger text represents higher frequencies of the terminology mentioned in written comments. The participants mentioned 'lighting', 'glare', and 'computer' the most. This clearly shows that lighting and visual comfort are considered important for computer based office tasks. Also, 'close', 'shades', and 'windows' were mentioned many times in written comments. This explains that the participants understand the influences of windows and shading devices on their lighting conditions.

Figure 4 shows visual comfort levels reported by the participants. Among 85 participants who answered the question, 82.3% of the participants reported no visual discomfort at their workstations. There are only 15 participants who reported either slightly uncomfortable or somewhat uncomfortable visual sensation. And, there is no report of extremely uncomfortable lighting condition. While 15 participants reported slight or somewhat visual discomfort, a total of 34 participants shared that they experienced either perceptible or disturbing glare. This discrepancy raises a question regarding accuracy and consistency of subjective evaluations. This clearly shows that different terminologies in similar questionnaire can cause inconsistent responses from a same survey participant. Even though the issue cannot be resolved here, this survey results explain that there are discomfort glare occasions experienced by occupants but the level of glare sensation is not severe.

Figure 3. Lighting related terminologies mentioned in comments written by the survey participants



a) Reported visual comfort levels



b) Reported visual discomfort sesation

Figure 4. Visual comfort levels reported by the survey participants.

3.2. Illuminance Data

Illuminance level ranges measured throughout the building are presented in Figure 5. This office building includes various space types which require different illuminance levels for occupants to perform specific visual tasks. Based on IES design guidelines, typical office space requires 300 lux at task areas while laboratory requires 750 lux for more accurate and detailed visual performance. Figure 5 compares the measured illuminance ranges in each space type to each space's recommended illuminance level threshold (shown in dashed black lines). The data clearly shows that the measured illuminance levels meet or exceed the recommended light level threshold for each space type. Open and closed offices have illuminance above 300 lux and laboratory has illuminance ranging from 600 lux to 1,600 lux. There is no space with insufficient light issues. Exterior illuminance level was measured at 5,200 lux at 2:10PM on August 14th, 2019.

3.3. Color Rendering Index

Figure 6 shows ranges of measured CRI values in different space types. CRI measures how well a given lighting condition renders different colors. 100 CRI value represents the highest color rendering and it is referenced to natural light which has full color spectrum of light. In Figure 6, all space types in the building have CRI value of 80 or above. The laboratory and kitchen are only two spaces with CRI

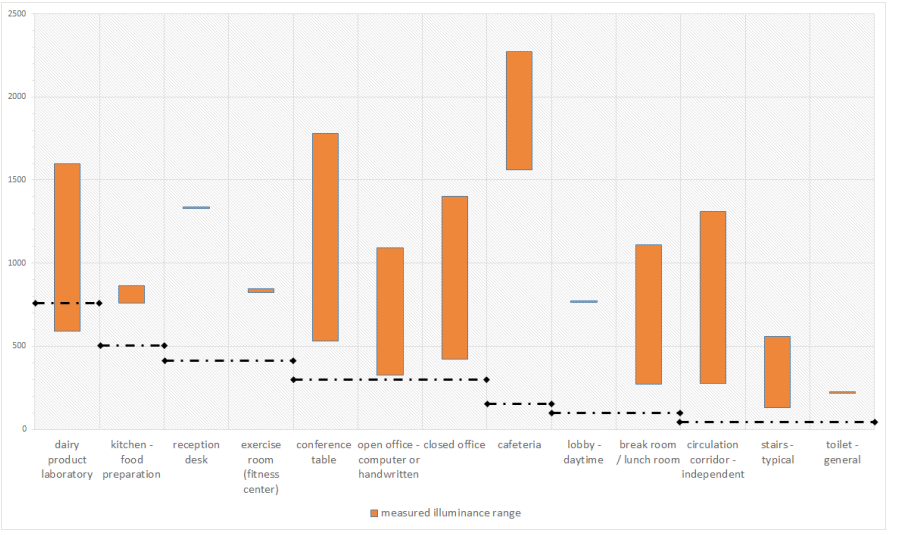


Figure 5. Measured illuminance levels in each space type and their comparisons to IES design guidelines

values slight lower than 80 CRI but their upper ranges are still at or above 80. These two spaces have slightly lower CRI values than the other spaces since they have lower light color temperature. It is typical that food processing spaces tend to have lower color temperature (cooler light) to maintain cleanliness and it causes somewhat lower CRI values. GSA P100 guideline recommends CRI values above 80. The latest version of Well Building Standard recommends either CRI values higher than 90 or CRI values higher than 80 with R9 value exceeding 50. This study did not document R9 values therefore it is difficult to determine whether or not this building meets the latest Well Building Standard requirement. However, the reception desk, open/private office, cafeteria, breakrooms, and circulation spaces have CRI value ranges above 90 which meets the requirement without confirming R9

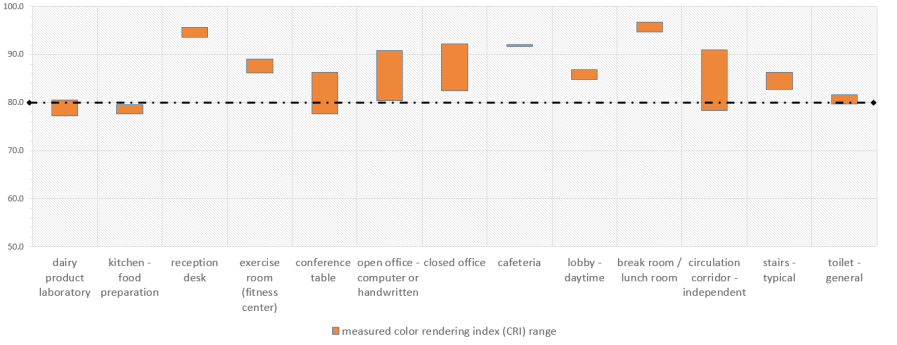

Figure 6. Measured CRI values and their comparisons to GSA P100 and Well Building Standards

value. In general, it is clear that this building has a very high quality lighting environment. As CRI and light color spectrum are important factors to affect human's circadian rhythm, it is recommended for lighting and daylighting POE studies should measure these lighting metrics.

3.4. Correlated Color Temperature

Measured CCT values widely vary depending on measurement locations. Both open and closed offices have CCT values ranging from 3,500K to 6,200K. This wide ranges of color temperature occur from the mixture of electric lighting and daylight in the office spaces. The electric lighting fixtures in the office spaces provide 3,500K which is typical in office spaces. However, natural light entering through the large windows increases CCT values and its influence varies depending on distances from the windows. It is found that workstations close to side windows has a very high color temperature around 6,000K because of large amount of natural light while workstations far away from windows has much lower CCT values around 3,500K. Same observation can be made for the corridor and circulation space. Different from these spaces, laboratory, kitchen, and toilet have lower CCT values at 3,000K because of limited exposures to natural light. Even though GSA P100 standard recommends CCT values lower than 4,000K, it is important to point out that CCT value itself does not determine quality of light. When natural light is introduced, CCT values can increase and CRI values can also increase. Recent studies show that high color temperature light in the morning can help office workers to maintain circadian rhythm when it is provided at a right time, period, and intensity.

3.5. Luminance Maps and Visual Discomfort Evaluation

Lastly, HDR photography was performed at various locations throughout the building. Luminance values were displayed in the false colored HDR image and each of the captured HDR scenes was analyzed by Daylight Glare Probability index to calculate

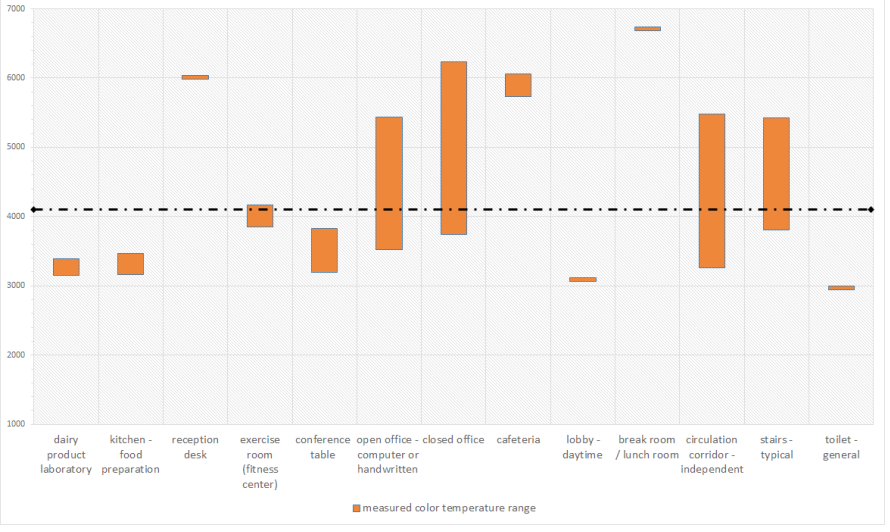

Figure 7. Measured correlated color temperature levels and their comparisons to GSA P100

visual discomfort sensation levels. Figure 8 shows four HDR scenes captured in angular fisheye lens inside open office, conference room, private office, and cafeteria. Luminance distributions in the false color images show that there are no glare sources in all of the captured scenes and the luminance values are considered to be visually comfortable based on the recently defined luminance thresholds for discomfort glare by various research groups (Suk et al., 2016; Shin et al., 2012; Wienold and Christoffersen, 2005). Relatively high luminance values were observed from the electric light sources but they are also within the acceptable range.

Daylight Glare Probability analysis evaluates imperceptible glare sensation from the four captured scenes. The open office has imperceptible glare sensation with 3% DGP score, conference room has 15% DGP score, private office has 2% DGP score, and cafeteria has 2% DGP score. Based on DGP metric, perceptible glare sensation occurs from DGP score of 35% (Wienold and Christoffersen, 2005). This results confirm that no significant visual discomfort issue can be experienced in the spaces.

CONCLUSION

Both qualitative and quantitative aspects of lighting environments were thoroughly documented inside the selected LEED Gold certified building. Online based occupant survey and physical lighting data collection methodology helped to reveal occupants' subjective evaluations with quantified lighting metrics. Majority of the participants reported visual comfort and satisfaction in the building. Measured CRI values are acceptable in most of the studied areas as they are above 80. Measured CCT values shows a wide range in different locations depending on the amount of natural light introduced into the spaces. Illuminance measurements also revealed that the desired illuminance levels were met or exceeded in every space of the building. Again, it is believed that natural light contributes to provide high illuminance levels, high CCT values, and high CRI values. This clearly shows the importance of daylighting design in buildings. Finally, DGP calculations of the captured HDR images confirm that electric lighting fixtures or natural light

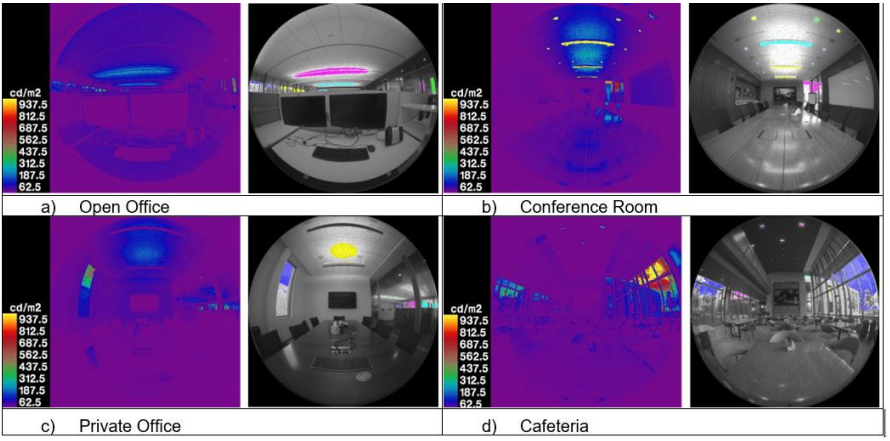

Figure 8. Captured HDR scenes and luminance distributions

through windows does not cause any serious visual discomfort to occupants. Both survey results and the field measured data agree that the project has successfully ensured visual comfort and direct outdoor views.

Compared to conventional post-occupancy study method that relies on limited illuminance measurements, this study utilized a combined methodology which analyzes both qualitative and quantitative aspects of lighting and daylighting in an office building. Use of a spectrometer helped to document important lighting parameters such as CRI and CCT. HDR imaging technique helped to document luminance distributions and allowed more in-depth analysis of visual discomfort sensation. Post-occupancy evaluation study is certainly challenging due to many unpredictable and uncontrollable factors including occupancy, sky condition, occupant behaviors, etc. and the challenge was also experienced in this study. However, it is believed that the proposed lighting POE study would allow more in-depth analysis of occupant experiences based on quantified lighting parameters.

ACKNOWLEDGEMENTS

Funding for this project was generously provided by Overland Partners, who also provided the design information for the project. The research team would also like to thank Grande Cheese Company for providing the building's operational information and allowing the team access to the building.

PAPER #7.16

NEW SYNERGIES BETWEEN RESEARCH, PRACTICE, AND EDUCATION FOR HEALTH AND WELLBEING OUTCOMES IN THE BUILT ENVIRONMENT

Altaf Engineer[a]
[a]University of Arizona, Tucson, Arizona

ABSTRACT

Traditionally, health-related design research has been carried out mostly in academic or research settings, while designing real-world built environments has been the domain of professional practice. Conventional roles of architects, however, are undergoing significant change with new research undertakings in professional practice (Hensel and Nilsson 2019). Recent years have seen the emergence of new human-centric research programs and initiatives at architecture firms on a global scale.

Practitioners, educators, and researchers now increasingly use evidence-based designs to create spaces that have healthy outcomes for people. The AIA-ACSA Design and Health Consortium, for example, has created a multi-disciplinary network to translate design and health research into practice for professionals, policy makers, and the public.

This paper examines the transformational impact of health research in architectural practice. Through a systematic review of health and built environment research carried out by design firms, the paper includes the study of different sources of information such as peer-reviewed publications, conference proceedings, white papers, webpages, and smartphone applications developed by these firms. A mapping exercise categorizes these studies by different typologies and research goals. It analyzes the research methods and findings presented in these sources and discusses real-world implications for design, professional practice, and future research.

Finally, this research highlights gaps that still exist in the field of design and health. To bridge these gaps and create new synergies between research, practice, and education a new model for research and design methodologies in health and the built environment called LEAPP is proposed and described in this paper.

KEYWORDS

Architects; health; built environment; design implications; professional practice.

INTRODUCTION

Traditionally, health-related design research has been carried out mostly in academic or research settings, while designing real-world built environments has been the domain of professional practice (Hensel and Nilson 2019). Conventional roles of architects, however, are undergoing significant change with new research undertakings in professional practice. Recent years have seen the emergence of new human-centric research programs and initiatives at architecture firms on a global scale.

Design practitioners often refer to their design processes as being human-centered. In recent years, their approach to design solutions and design-making processes in their publications, websites, whitepapers, and advertisements have been frequently described as being human-centric and evidence-based. Indeed, practitioners now increasingly use evidence-based design recommendations suggested by educators and researchers to study and create spaces that have healthy outcomes for people. The AIA-ACSA Design and Health

Consortium, for example, has created a multi-disciplinary network to translate design and health research into practice for professionals, policy makers, and the public (Design & Health Consortium).

Evidence-based design is design-making that is grounded in research and tested in practice (van Aken and Romme 2012). The validity of evidence-based design principles depends on how well they are connected to the body of scientific knowledge and the extent to which the principles have been tested in practice. The notion of 'testing' refers to the reviews of the building or spaces from user experience, critics reviews, and performance assessment. Evidence-based design is meant to develop prescriptive knowledge and solutions that serve to improve professional practice (van Aken and Romme 2012).

Human-centered designs for spaces are solutions that emerge from involving the users of that space (Crandal, Michelle 2019). A myriad of design and design-related fields now advocate this approach. These include usability engineering, user-centered design, participatory design, and experience-based design (Johnson, Slavo and Zoetewey 2008). Architectural discourse ideally, is inspired by users' needs, and showcases skills that can address those needs. Design research methodologies serve as tools and conceptual frameworks to develop real-world solutions.

Human-centric and evidence-based design processes identify specific problems and acknowledge their conditions, locations, target populations, and other variables. For this study, the sources that were collected and analyzed, share a focus on health research in architectural practice and involve methods that address specific space typologies. Every design firm studied comes with its own variation of these methods, processes, and outcomes.

In this study, we connect professional practice in the field of design and health by firms to the identification of any evidence-based and human-centered research methods that they may have used. The goal is to reveal the influence, outcomes, and limitations of design and health related research conducted by design firms. Importantly, it also highlights the gap in the documentation of actual built projects versus the documentation of research and design processes by firms. Several methodologies and mechanisms of their evidence-based and human-centered processes or practices, therefore, are invisible to educators and researchers in academia, and industry colleagues. The research knowledge that is presumably developed for problem-solving and practice, therefore, becomes limited in its influence in the field of design and health if it is not documented and published.

1. METHODOLOGY

1.1. Approach

The research methodology consists of a systematic content analysis and mapping exercise of peer-reviewed publications, conference proceedings, white papers, websites, and smartphone applications created by professional design firms. These sources of information were scanned for scientific research and evidence-based outcomes in the field of design and health. A conceptual map was then created to identify and categorize the transformational impact of health-related research in architectural practice, and identify its gaps. Solutions are proposed thereafter, to create new and effective synergies between research, practice, and education.

1.2. Examing the role of health research in architecture practice

58 architectural design firms were identified after running a web search for practices or practitioners that focused on design and health research or projects or both, as

part of their work portfolio. The selection of these firms was not restricted to any particular geographical area or region; this study, therefore, is international in scope. An initial review of design firms' websites led to the following questions: How are design practitioners aware of concerns related to health and the built environment? What is their approach to solving problems in this field? What are their sources of information for decision-making which ultimately leads to design solutions? And importantly, how are these research and design methodologies made available publicly – to peers in the industry, scholars and educators in the field, and other stakeholders? The sources of information that were checked for included but were not limited to, news releases, popular press, academic or peer reviewed or scholarly articles, conferences, white papers, or a combination of any of these venues.The inquiries led to a systematic content analysis and statistical modeling method known as topic modeling which was used to collect and analyze different elements of the data. This method was followed by the development of the conceptual mapping and frameworks to describe how design research methods are used by the firms in the field of health and the built environment, their impact, and their gaps.

1.3. Topic modeling

The topic modeling study of the 58 sources includes keyword identification, frequency analyses, and Pearson correlations. The keyword identification process consists of finding and sorting keywords or key phrases into different themes within the sources analyzed. The results were annotated using a controlled tagging process in the computer program Hypothes.is.[1] The annotations revealed the most frequently used words or keywords that related to each theme. These results were then analyzed to answer the questions which were discussed earlier. Four main, recurring themes were identified and used to group and organize keywords and text as follows:

1. Problem awareness: This theme included an awareness of issues and concerns related to health, wellness, medical or health facilities, or medical or health treatment in the built environment.
2. Design firm's culture or values: This included all the references to the firms' mission, vision, featured projects, abstracts, and design project highlights.
3. Sources of background information: This theme includes references to previous experiences, motivations, client's requirements, trends, common sense design guidelines, research, news or economic benefits.
4. Design and research results: This included the documentation of all built projects, publications or references to publications, posted data, references to conference presentations, white papers, news, applications, etc.

The text connected to each theme in Hipoyhesis was further analyzed to understand its context or how it was referred to in the source. The frequency analysis involved exporting the meta-data from Hipothesis and sorting out the information by the focus area as described by the firms, the potential research areas based on their expertise, and the use of the products that they offer. Once this was completed, a Pearson correlation was applied to the datasets to find any significant associations between data sets and measure their strength.

2. RESULTS

The search for architecture firms with any linkages to health-related work resulted in 58

[1] https://web.hypothes.is

different national (based in the United States) and international firms. The results of the content analysis and topic modeling showed findings related to the primary and secondary areas of focus of their work, and how this was highlighted in websites, publications or other means to attract viewers' attention.

2.1. Primary themes in design and health practice

21 firms were found to have building typology as primary focus, i.e. they claim to have expertise in designing healthy environments for a variety of different building types. Nine firms mention customized user and demand-based services in any building type. 19 firms emphasize the use of special technology or a special skillset to solve unique design challenges to create healthy solutions for spaces. 11 firms describe their design focus as evidence-based. 17 firms have more than one area of focus: two link the building type with user needs or user-experience, three link a special technology or skillset to meeting user needs, eight link special technologies or skillsets with evidence-based design outcomes, two link designing different healthy building types to the use of special technologies or skillsets, and two link the users, skillsets, and evidence-based designs together. Figure 1 shows the number of architecture firms sorted by how they advertised their strengths or areas of primary focus in design and health.

The definitions of evidence-based practice and human-centric approaches by design firms were found to vary, but were mostly pragmatic and related to real-world projects. In one instance, evidence-based is described as *'a way to validate the design methods and architecture practice that incorporates de learning from experimental/ empirical experimentation during their own client-architecture relationship, sometimes based in field-related documents of various sources'*. Another firm described a human-centric approach as *'a consumer/client driven process that attend the specific needs prioritizing health, wellness, harmony, and the environment*'.

2.2. Recurring themes in design and health practice

The data extracted by the controlled tagging tool showed three main tendencies by firms in the field of design and health: 1) their main area of focus of the architecture practice within the field of design and health, 2) an awareness

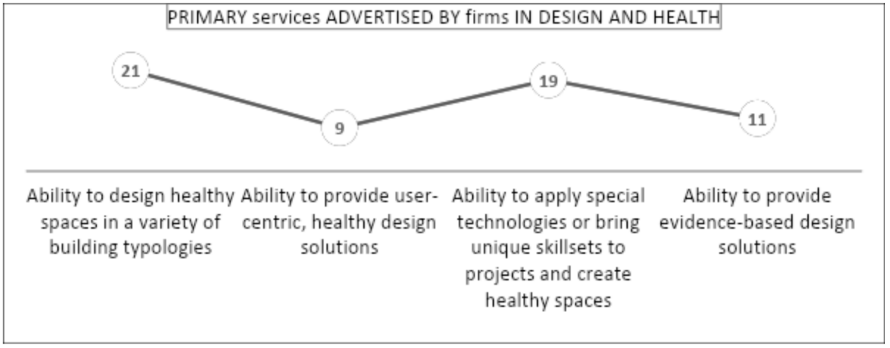

Figure 1. Number of firms sorted by their advertised primary areas of focus or strengths in the field of design and health. Source: Author.

of existing problems or concerns related to human factors and the associated areas of their existing or potential research expertise, and 3) the proposed solutions, outcomes or products of their work. An analysis of 60 different references or descriptions as to what the firms defined as the main focus of their architecture practice showed that most firms preferred writing about their general expertise and specialties, while fewer showed an awareness of issues and concerns in health and the built environment or mentioned the sources of their research or even inspiration, and very few published the outcomes of their research.

The most frequent theme was the one for proposed solutions which showed 49 keywords or text references, followed by the 33 references to the awareness of a problem to be solved. Lastly, there are 22 references to a source or multiple sources of information or evidence that led to a design solution. Quite often, however, design solutions and built projects were described without discussing problems, issues, client or user needs first. The results of these recurring theme frequencies are shown in figure 2.

The results of the Pearson correlation are shown in Table 1. They revealed an insignificant association between *problem awareness* and *proposed solutions* (-0.25) which indicates that firms in design and health are unlikely to link *proposed solutions* with *problems, issues, or concerns*. This may also indicate that they did not follow any specific research methodology while working towards design outcomes or if they did, then they did not document or describe in any way. Similarly, the correlation between *proposed solutions* and *sources of information* was weak or insignificant (0.0029). There was also found to be no association between *problem awareness* and *sources of information*. Further, only ten firms mentioned three of these themes in their descriptions, 24 use two themes, and 26 only mentioned one themes.

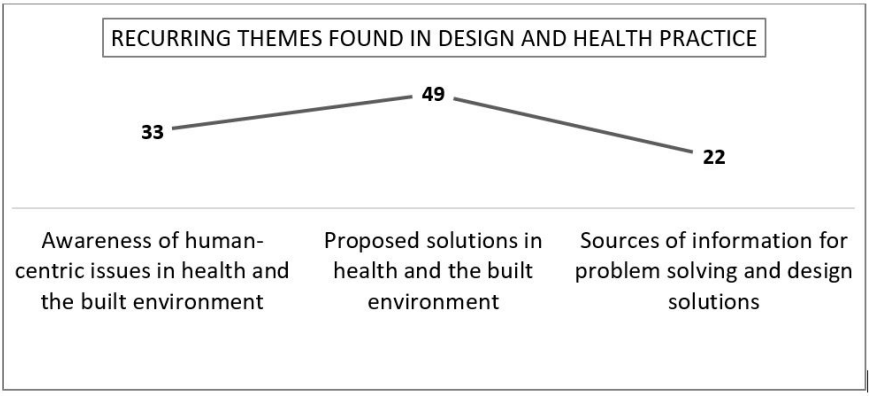

Figure 2. Frequencies of recurring themes found in design and health practice. Source: Author.

Themes		Results of Pearson correlation
Problem awareness & Proposed solutions	-0.26	insignificant
Proposed solutions & Sources of information	0.00	insignificant
Problem awareness & Sources of information	-0.01	insignificant

Table 1. Results of the Pearson correlation test between different themes in design and theme. Source: Author.

2.3. Specific reserach areas in design and health

The 58 architecture firms studied mentioned or referred to having an expertise in 73 different research areas in total. These 73 existing or potential research areas were derived by reviewing all the keywords or text from the content analysis and topic modeling exercises described earlier. The following primary fields of research expertise and knowledge areas were found in the analysis of firms of design and health: *health* with 35 references, *environment* with 13, *building technology or materials* with 17, *special talent or services offered or skillsets* with 16, particular research *methods or approach* with 50, and *economic benefits* with three references. These results are also shown in figure 3.

Since *particular research methods or approach* were found to be most frequently mentioned, another Pearson correlation was run to compare it with *health*. The relationship was found to insignificant as well, as shown in Table 2 below. Two firms claimed to have four research areas of expertise in design and health, while eight firms mentioned three research areas each. 40 firms mentioned two research areas each, and 23 claimed to have one research area of expertise. In all 58 cases, these existing or potential areas of research were found within the overall description of the architecture practice and not on another specific webpage, portfolio, or another document or part of the website.

Themes		Results of Pearson correlation
Health & Particular research methods or approach	-0.26	insignificant

Table 2. Results of Pearson correlation between health and particular research methods or approach by firms in design and health. Source: Author.

2.4. Documenting or advertising the work

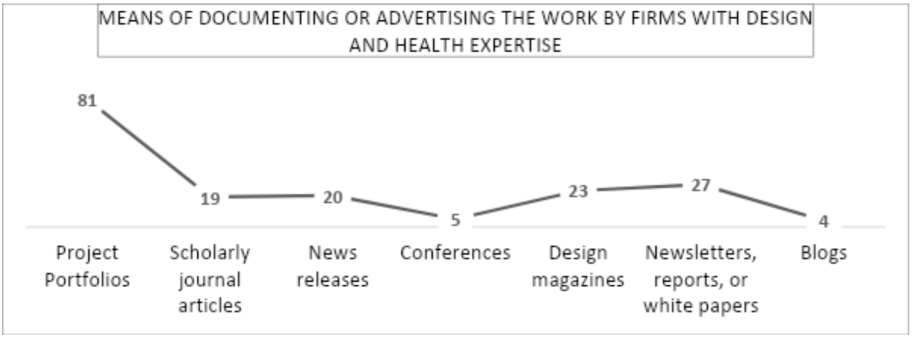

Figure 4. Means to document or advertise projects in design and health by architecture firms. Source: Author.

The results of the frequency analysis shown in figure 4 reveal that 81 firms use their *project portfolios* to showcase their expertise, followed by 27 references to the use of *newsletters*, *reports, or white papers*, 23 to *magazines*, 20 to *news releases*, and 19 to s*cholarly journal articles*. *Conferences or blogs* were found to be significantly less used in the field by firms as a way to advertise, present, or document their work.

3. DISCUSSION: SYNERGIES BETWEEN RESEARCH, PRACTICE, AND EDUCATION

The findings of this study reveal different approaches adopted by design firms that operate at a global or national level in research methodologies and design solutions for projects related to health and wellbeing in the built environment. A larger study which includes surveys and interview of principals, managers, and employees would be required to make more significant conclusions about how the work done by these firms creates linkages with peers in the industry, and has an impact on research, education, and policy in the field. The results of this preliminary study, however, indicate that design firms were focused mostly on providing solutions for different building typologies that were advertised as healthy solutions for users, clients, and stakeholders. There was often an emphasis on providing user-oriented and evidence-based design solutions, but descriptions or mentions of how these concepts were actually implemented in real-world projects were either inadequate or completely missing.

A few firms were found to document or share their approach, strategy, or research methodologies to solve particular problems and meet user needs. These approaches, however, were mostly limited to one or two types that were used across a range of building and interior design projects. Further, it appears that the reason for these processes not being mentioned or documented most of the time, is not a lack of skillsets or the use of special or state-of-the-art technologies or equipment. The teams' talents, tools, and experience in fact, appear to be very well advertised up-front, presumably, to attract clients and generate more work. This may indicate, therefore, that firms do not believe specific research methodologies to be a valuable means of attracting more clients. Evidence in the field of health and the built environment, however, reveals quite the opposite; design solutions need to be well-grounded in research findings

in the field to satisfy user-needs and create healthy environments. By not documenting or sharing research and design methodologies in the field, therefore, design firms miss important opportunities to grow the field of design and health by nurturing more research and increasing the field's knowledge base. This phenomenon may also have a long-term impact on meeting user needs as well as future research, education and practice goals. Additionally, a lack of awareness of existing and latest research could also lead organizations to reinventing the wheel instead of driving innovation in the field.

A new conceptual framework, therefore, for creating more synergies between research, practice, and education is urgently required. A five-step model known as **LEAPP** is proposed as part of this framework, consisting of the following steps:

1. A **L**iterature review on the specific topic and drawing from existing research on spaces of a similar type and function as the new ones to be designed. Creating a customized research methodology based on the knowledge gained in this process.
2. Conducting **E**valuations at the pre-design/ pre-occupancy consisting of focus group meetings, surveys, interviews, measurements, virtual reality studies, or a combination of these methods, to understand client requirements, user needs, or evaluating existing spaces to improve or redesign.
3. **A**pplying research findings from the previous step and developing a design solution in response.
4. Conducting a **P**ost-occupancy evaluation and comparing it to pre-design findings, making improvements to the space based on these findings if possible, and learning from the design outcomes.
5. **P**ublishing the design research methodologies and findings in different formats including but not limited to peer-reviewed journals, news releases, popular press, white papers, and conference presentations and proceedings. Additionally, these publications could be used to increase the firm's profile and, in its marketing, and branding strategies.

By following the steps in LEAPP, design and practitioners may be successful in increasing the dissemination of knowledge, make a bigger impact on the field of design and health, and create more synergies with research, education, and practice.

CONCLUSION

Firms committed to designing healthy environments as one of their primary focus areas or building types may have areas of special expertise that align with human-centric and evidence-based approach to design. However, they miss opportunities to disseminate knowledge by not documenting their work in scholarly journal articles, white-papers, conference presentaions, or proceedings. Clients, potential users, and other stakeholders are a valuable source of information in research and design processes. Users should be seen as informants, consultants, and participants of buildings and spaces from the very beginning of the design process.

To create a better impact, design firms must also increase the scope and role of their deliverables. Due limitations in cost, time, and required expertise, however, firms cannot be expected to conduct original research studies for every design project. There may also be some cultural or pragmatic challenges in their application. To counter these limitations, a five-step process known as LEAPP is proposed, to break down and simplify the research process, help in its broader understanding, and to market it better as part of the project. LEAPP, as discussed in detail earlier, suggests that the design of building projects may be based on existing research findings on design and health, pre-design evaluations, as well as post-occupancy evaluations after their

design and construction. Importantly, these processes and methodologies followed by the design team must be documented and shared among the larger and more diverse community to create better and impactful synergies with education and research.

Limitations of the study

This study is limited in scope and scale. To make significant conclusions, a larger study which includes an extensive survey and interviews of design practice leaders, employees at different levels, clients, and other stakeholders, is highly recommended. Five out of the 58 architecture firm websites were protected against tagging tools and their data, and were not included in the frequency analysis. Some reports and newsletters mentioned by firms on their websites were also unavailable for a qualitative review. White papers did not appear to be used to by the firms at all, and therefore, were not included in the analysis as well. A larger survey, however, may find white papers which reveal more research and design methodologies and potential synergies between research, education, and practice.

ACKNOWLEDGEMENTS

We recognize the contribution of Hipothesis, a nonprofit organization in making its controlled tagging technologies available as open-access for the topic modeling analysis. I would also like to acknowledge the contributions of my research assistant Dr. Sandra Bernal for her assistance in collecting and analyzing the data for this study.

PAPER #7.17

RETHINKING SUSTAINABLE DEVELOPMENT IN EUROPEAN REGIONS BY USING CIRCULAR ECONOMY BUSINESS MODELS

Begoña Serrano-Lanzarote[a], Nuria Matarredona-Desantes[a], Vera Valero-Escribano[b], Cristina Jareño-Escudero[b]
[a]Universitat Politècnica de València, Valencia, Spain
[b]Instituto Valenciano de la Edificación, Valencia, Spain

ABSTRACT

In essence, Circular Economy (CE) is about moving from an unsustainable linear system of materials usage and waste production to one of the regeneration of resources. CE has lately developed into a rapidly progressing and competitive field of business and innovation. CE business models can be seen as tools in reducing waste, generating resource efficiency improvements and lessening the environmental impacts of industrial production and creating social sustainability. However, it's still often unclear what type of negative environmental and economic impacts CE business models may bring about. In the REDUCES project, the potential environmental impacts of CE business models are mapped and tools will be discovered for regions to not only promote the business models most suitable for their regional contexts, but also to assess the potential environmental impacts they may entail. The tools will be reviewed and evaluated by the partners and stakeholders during the projects, focusing on the previously recognised most important categories of CE business models. In order to make informed policy decisions about both economically and environmentally most viable business models, their impacts need to be thoroughly assessed. There is a growing need for a more comprehensive understanding of regional and local aspects of the transition towards a CE and of recognizing the most promising sectors for sustainable smart specialisation. REDUCES forms a cooperation network of regions that are on different levels of CE development and have a strong shared will on further supporting their region's businesses in transitioning to a CE. The exchange of experiences and knowledge within and between the regional authorities is key in developing the best action plans to support environmentally sustainable business models for each region and policy. REDUCES results in best practices and policy recommendations which will significantly benefit public authorities and institutions in supporting CE transition.

KEYWORDS

Circular economy; business model; Comunitat Valenciana; sustainability; regional policies.

INTRODUCTION

The idea for the project REDUCES originates in the recognised need to support the transition to a circular economy (hereinafter CE) on policy level in order to accelerate the transition to sustainable, resource-efficient regional economies, to tackle climate change and decrease environmental damage caused by linear business models. In order to achieve sustainable change, it is essential that regions not only recognise the value of circular business but also that the policy environment supports and activates businesses to implement these business models.
A case-based interregional exchange of experiences forms the basis of the REDUCES approach. The aim is to review best practice

CE business models in regional context as a driver for environmentally sustainable economic growth. Five general topics of CE business models have been recognized to focus on: product life extension, product as a service, sharing platforms, renewability, resource efficiency and recycling. In addition, the crosscutting themes of regulatory and governance issues as well as all dimensions of sustainability in CE are considered.

To form a better picture of regional status of CE integration, a status quo of CE business environment and critical environmental considerations in each partner region has been developed in the framework of the project. This is considered as the starting point for the later action plan development.

We must emphasize that although the approach of the project is CE in general terms, in the case of the Valencian Community and due to the political instrument of application (Decree 151/2009, basic design and quality requirements in housing and accommodation buildings), we approach CE from a general perspective to later focus on CE in the built environment and the housing sector. This paper presents the main results of the analysis on the state of the art of the CE in the Valencian Community.

1. MAIN CHARACTERISTICS OF COMUNITAT VALENCIANA REGION

The Valencian Community is a Spanish autonomous region with 4,946,233 inhabitants in 2018 (10.6% of the Spanish population). With an area of 23,255 km² (4.60% of the national extension), it is the 8th region in Spain by area. It is in the east and southeast of the Iberian Peninsula, on the coast of the Mediterranean Sea, and is divided into 3 provinces, Alicante, Castellón and Valencia, 34 counties and 542 municipalities.

The gross domestic product (GDP) has increased in recent years and stands at 108.6 billion euros in 2017 (9.3% of national GDP). According to Eurostat, the GDP per capita in the Purchasing Power Standards was 24,300 in 2017, a figure that has steadily increased since 2013 (20,900). This ranks the region in position 12 among the 17 Spanish autonomous communities, below the national averages (27,600) and of the EU-28 (30,000) (European Commission 2010).

The economy is strongly service-based, the service sector represents 71% of the regional gross value added (GVA) in 2018, which represents approximately 64% of the regional GDP. The activities with the greatest weight

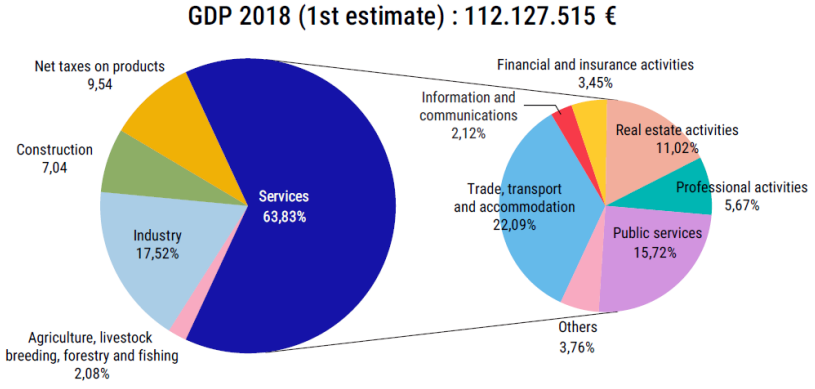

Figure 1. Gross Domestic Product of the Valencian Community. Source: (Consellería de Economía Sostenible, Sectores Productivos, Comercio y Trabajo. 2020)

are those related to commerce, transport, and hospitality (22.09%) and real estate activities (11.02%), which together represent more than 50% of activities related to the service sector (Consellería de Economía Sostenible, Sectores Productivos, Comercio y Trabajo. 2020).

The tourism sector, which began to develop widely in the 1960s and early 1970s, has progressively become one of the main wealth-generating activities in the region, not only for its direct contribution but for the expansive effect it has had on a large group of related activities. The region welcomes 28.7 million tourists each year (residents and international), with 177.3 million overnight stays, and 12,580 million spending (includes origin and destination), which represents an economic impact of 14.6% participation in GDP and 15.1% participation in employment (Turisme Comunitat Valenciana 2018).

The strategic industrial sectors in the Valencian Community are Tiles and ceramics; Leather and shoe industry; Toys and games; Wood and furniture; Textile and clothes; and Automotive industry. There are many companies in these sectors in the region, which represent a high percentage in the country in general, so that they are important for the general economy in Spain. The financial and economic crisis that started in 2008, had an impact on the global economy, and some of these sectors, such as ceramics and furniture very directly related to construction, were particularly affected (European Commission 2010).

Regarding active population during 2018 was 2.04 million people, with the Services sector standing out from the rest of sectors with 73.5% of the regional total, with industry lagging behind with 17.1%, followed by construction with 6.4% and agriculture with 3% (Consellería de Economía Sostenible, Sectores Productivos, Comercio y Trabajo. 2020).

Regarding the number of active companies based in the Valencian Community, the latest published data (2018) show that of the

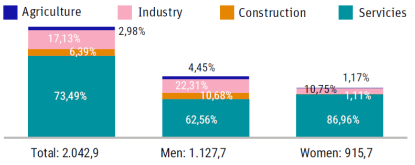

Figure 2. Employed population (thousands). (Consellería de Economía Sostenible, Sectores Productivos, Comercio y Trabajo. 2020)

total number of companies, 80.7% belong to the service sector, 12.2% to construction and 7.2% to industry, representing growth compared to the previous year above the average for industrial companies (4.69% more) and construction companies (4.44% more) while the service sector it grows below the average (1.23%). The average in the Valencian Community shows a growth close to 2% . Regarding the size of the companies, in number of employees, more than half (53.7%) are companies without employees, 41.7% have between 1 and 9 employees, 3.9% between 10 and 49 employees and only 0.7% (2,381 companies) have 50 or more employees. During 2017, companies with 50 or more employees, increased by 6.97%, followed by 10 to 49 employees companies, which increased by 5, 82%. Companies with between 1 and 9 employees and without employees grew by 1.88% and 1.49% respectively (Conselleria de Economía Sostenible, Sectores Productivos, Comercio y Trabajo 2019).

As regards the construction sector, during the 2000s, it suffered exorbitant and unsustainable growth. Thus, its weight increased to represent in 2008 more than 12% of regional GDP. The end of the real estate boom from 2008 translated into a decline in the weight of this activity, reaching a low in 2014 with 5.8% of regional GDP, a percentage similar to the national average (5.1 %) in that same year. As of that year, the weight of the construction sector has increased slowly

and steadily, but without reaching the values prior to the crisis. The economic forecasts published by different organizations for the coming years augur an increase in production, although with lower growth rates, data that are also being revised more and more downward.

2. REGIONAL CIRCULAR ECONOMY PROFILE

To get an idea of the state of the CE in the region, it is essential to start by making a brief overview of the current regulatory framework and the initiatives promoted by the different administrations, national, regional and local, with the objective to redirect the economy, production and consumption models towards circular models.

2.1. National regulatory framework

At the national level, the recently approved Spanish Strategy for Circular Economy (Ministerio para la Transición Ecológica y el Reto Demográfico 2020), its successive three-year action plans to be developed, and the Pact for a Circular Economy should be highlighted.
The Spanish Circular Economy Strategy (hereinafter EEEC), España Circular 2030, lays the foundations for promoting a new production and consumption model. The strategy aligns with the objectives of the European Union CE action plans, in addition to the European Green Pact and the 2030 Agenda for sustainable development.
For the implementation of the EEEC triennial action plans are foreseen, the first one, it is expected to be presented at the end of 2020 and will cover the period 2021-2023.
The strategy marks the following quantitative objectives to be achieved by 2030:

• reduce national consumption of materials by 30% in relation to GDP, compared to 2010
• reduce the generation of waste by 15% compared to 2010
• reduce the generation of food waste throughout the food chain: 50% reduction per capita at the household and retail consumption level and 20% in the production and supply chains from 2020
• increase reuse and prepare for reuse until reaching 10% of the municipal waste generated
• improve the efficiency in the use of water by 10%
• reduce the emission of greenhouse gases below 10 million tons of CO2 equivalent.

The EEEC identifies six priority sectors of activity: the construction, agri-food, fishing and forestry, industrial, consumer goods, tourism and textile and clothing sectors. And it mentions as key policies to advance on the CE the policies related to economy, taxes, employment, R&D&i, consumption, industry, water, agriculture and rural areas development.
On the other hand, the Pact for the Circular Economy (Ministerios de Agricultura y Pesca y de 2017), signed by more than three hundred entities, is an initiative promoted by both the Ministry of Agriculture and Fisheries, Food and Environment, and the Ministry of Economy, Industry and Competitiveness, that seeks to involve the main economic and social agents of Spain in the transition towards this new economic model.

2.2. Regional regulatory framework

The Valencian Community has not yet started the procedure to prepare a Circular Economy Strategy. However, in October 2018 the president of the Generalitat Valenciana announced the will to promote a pact for the Circular Economy (Generalitat Valenciana 2018) participated by administrations, business organizations and citizens.
Likewise, the Generalitat Valenciana has other plans and programs that contribute to the fulfillment of the objectives of the EU in

terms of CE, among which we can highlight the following ones:

• Document d'ELX (Conselleria de Hacienda y Modelo Económico. Generalitat Valenciana 2016): Base document and guiding elements for the transformation of the economic model of the Valencian Community, whose objective is to lay the foundations for the Valencian Community to advance towards an economic model based on knowledge, innovation, openness and outside connection, articulated on the principle of sustainability, both environmental, productive and social. It defined ten strategic lines that later generated the structure of the Action Plan for the Transformation of the Economic Model 2017-2027 (Conselleria de Hacienda y Modelo Económico, 2017).
• Action Plan for the Transformation of the Economic Model 2017-2027: consists of an economic diagnosis, objectives and key strategic initiatives, as well as a monitoring and evaluation system. The proposed action plan is aligned with the Sustainable Development Goals and with the principles of the Europe 2020 Strategy. Both line 2, Promoting a modernising transformation of the Valencian productive structure, and line 5, Promoting the creation of sustainable employment and the social economy, contain objectives related to the CE, such as: O2.2: Development of new activities aimed at a sustainable and circular economy, O5. 1: Boosting the generation of sustainable, quality employment, O5.2: Implementing social responsibility policies and actions in the Valencian economy, O5.3: Promoting the economy of the common good, O5.4: Increasing the number and size of social economy organisations. Line 1 (Developing the innovative capacity of the productive fabric by strengthening the Valencian innovation system), focuses on developing initiatives related to innovation as a key element for promoting economic growth, trying to take advantage of the resources available in universities, technology centres and knowledge-intensive companies. Within this framework, the Valencian Innovation Agency was created in 2017 to coordinate the Innovation Strategy of the Valencian Community. Along the same lines, the execution of the Intelligent Specialisation Strategy for the VC, RIS3-CV (Generalitat Valenciana, 2016), is specifically included as one of its objectives.
• Intelligent Specialization Strategy of the Valencian Community, RIS3-CV, constitutes the strategic agenda to contribute to the transformation of the Valencian production model from research and innovation, for the 2014-2020 programming period. Based on the specific context of the Valencian economy, the result of a SWOT analysis, a strategic framework is built, which is expressed in a vision, a mission and some values. This framework culminates in the prioritisation matrix which includes the main options for regional development based on research and innovation. The matrix integrates the transversal axis of sustainability, which is essential to promote a low-carbon economy, in line with European policies. It is subsequently specified in objectives, which will frame the expected results and indicators for their monitoring. In the specific case of the CE in the built environment, Axis 2 is especially noteworthy. Innovative Product - 2.2 Habitat: housing and its environment, This axis includes the manufacture of consumer goods linked to the habitat and its surroundings, such as ceramic and natural stone coatings and materials for the home, lighting, furniture, home textiles, architecture, home automation, urban environment, in which its Growth and competitiveness necessarily pass through the generation of innovations focused on the product. The environment of HABITAT stands out for the demand for the development of new materials and advanced, sustainable products and with new applications of added value, together with the need for collaborative processes in production and distribution systems, mainly international, for which the

use of technologies ICT and logistics, along with materials and environmental appear as relevant.

• Acord del Botànic, June, 2019, axis 1 includes the objective of promoting a Law for the Circular Economy, in line with the principles of the European Union (Accord del Botànic 2019).

Other regulations that contribute to the CE in more specific aspects are the Strategy of the Industrial Policy of the Valencian Community 2020 (EPI-2020) and Strategic Plan of the Valencian industry 2018-2023 (PEIV), the Energy Savings and Efficiency Plan, Promotion of Renewable Energies and Self-consumption in buildings, infrastructures and equipment of the public sector of the Generalitat (PAEEG), the Valencian Ecological Production Plan, the Valencian Strategy for Climate Change and Energy 2030, the Rural Development Plan 2014-2020, the Territorial Action Plan for the Green Infrastructure of the Coast of the Valencian Community (PATIVEL), and the revision and update of the Comprehensive Waste Plan of the Valencian Community (PIRCVA), covering the period 2019-2022.

2.3. Relevant actors or entities for CE in the region

Actors or entities, within the public administration, relevant to transform the Valencian economic system towards a more circular model include the Valencian Agency for Innovation (AVI) and Valencian Institute of Business Competitiveness (IVACE).

• The Valencian Agency for Innovation (from now on AVI) is the meeting place for all the agents of the Valencian Innovation System (SVI): research centres, technological institutes, financial entities, Public Administrations and businesses. Its mission is to improve the region's productive model through knowledge and innovation, to achieve intelligent, sustainable and socially cohesive economic growth.

The AVI oversees designing and coordinating the innovation strategy of the Comunitat Valenciana and promoting the strengthening and development of the Valencian Innovation System as a whole. The participation of the agents of the Valencian Innovation System (SVI) is directly articulated in its organs: Board of Directors, Valencian Innovation Council (CVI), Strategic Innovation Committee (CEI) and Specialized Strategic Innovation Committees (CEIE). The latter are the specialised working groups created in each of the priority areas of innovation identified: *Sustainable habitat, Emergencies, Health, Agri-food, Enabling technologies for the new economy, Automotive industry and sustainable mobility, and Circular economy.*

The work-teams of these committees, identify the main challenges in each area, establish the short-medium term priorities, propose innovative solutions and define the actions to be implemented in the region's business environment, suggesting tools and incentives to maximize their impact.

The challenges prioritized by *Sustainable Habitat Committee,* which are related to the built environment and building sector are:

- Optimisation of the real behaviour of buildings and dwellings to improve their performance and maintenance, their interoperability and/or their adaptability,
- Implementation of more sustainable building materials and systems
- Nearly zero energy buildings
- Improved integration of the changing demands and needs of building and housing users.

The first and last challenges mentioned above, with their solutions and actions are connected to the business models, proposed in REDUCES, of Product life-extension, while de second and third challenges, are associated

to the business models of Renewability and Resource Efficiency and Recycling.
The Circular Economy Committee prioritized the following three challenges:

- Ecodesign
- More sustainable consumer goods
- Waste recovery and use of reclaimed water.

Challenges, connected to the business models of: Product life-extension, Renewability and Resource efficiency and recycling.
Additionally, the AVI has different instruments and lines of action to transform the productive system, among other provides grants through competitive calls, oriented to different objectives, in which the challenges and solutions proposed in the above mention committees are prioritized.

• The Valencian Institute of Business Competitiveness (IVACE) is a public body belonging to the Valencian Government, attached to the Ministry of Sustainable Economy, Productive Sectors, Commerce and Labour of the Valencian Government. It is the regional development agency in charge of promoting a new economic, sustainable and inclusive model in the Valencian Community, promoting the competitiveness of companies through R&&i, internationalization and entrepreneurship, promoting energy development sustainable and promoting infrastructures, industrial services and attracting investments.
The IVACE is organized around 4 areas: Innovation, Energy, Internationalization and Business Parks. Among its functions, it is especially worth mentioning: To manage aids and incentives aimed at the creation, modernisation and internationalisation of regional companies, to promote and assist companies in their activity and internationalisation, to facilitate companies financing, to promote research, development and innovation infrastructures, scientific and technological parks and institutes and business centres, to foster energy conservation and saving measures in all business sectors, and to promote sustainable mobility and rational use of energy.

2.4. Circular Economy projects in the Construction sector and other related sectors (ceramics or furniture sector) in the Comunitat Valenciana

Additionally, in the Annex of the report "Regional Circular Economy Status Quo, Valencia, Spain 2020", a list of projects, participated by regional stakeholders, in which Circular Economy principles are included has been compiled. These are projects at different scales (international, national, regional) and from different programs (H2020, Interreg, IVACE, etc ...), in which partners of the Valencia Region have participated (technology centers, research institutions, companies, business networks etc. ..), developed during the last 10 years, within the Construction sector or other related sectors (ceramic, furniture, etc ..). The analysis performed tried to stablish the links with the main themes for CE business models that have been identified in REDUCES project.: 1) product life extension 2) renewability 3) product as a service 4) sharing platforms 5) resource efficiency and recycling
The main results of this analysis are summarized below.
Of the 28 projects analyzed, 16 (57%) of them are currently underway. There are 34 different stakeholders (technology institutes and centers, research institutions, businesses organisations, etc.) participating, most of them involved in several of the projects.

*Themes of CE Business models: 1- Product life-extension, 2- Renewability, 3-Product as a service, 4-Sharing platforms, 5-Resource efficiency & recycling.

Table 1. CE projects participated by regional stakeholders. Own development.

3. THE POLICY INSTRUMENT ADRESSED IN REDUCES PROJECT AND OTHER RELATED POLICIES

As stated before, the main objective of REDUCES project is to adapt and update regional political instruments in order to incorporate criteria that favour the creation and adoption, by the companies, of environmentally sustainable business models based on the principles of circular economy. The political instrument of application in the Valencian Community is Decree 151/2009 (Conselleria Medio Ambiente, Agua, Urbanismo y Vivienda, 2009) which approves the basic design and quality requirements in housing and accommodation buildings.

3.1. Policy instrument: DC09 Regulations on Habitability in Housing

This Order approves the design and quality conditions that must be met by new buildings intended for housing, those that contain adapted housing, accommodation buildings or those that are subjected to refurbishment in any of these cases.
The Decree regulates functional aspects of the dwellings and the buildings: such as the minimum surfaces of the spaces, the relationship between the different spaces or enclosures, the conditions that the circulation spaces (horizontal and vertical) must fulfill within the dwellings and buildings, minimum and / or mandatory equipment that a dwelling and building must have, it also regulates certain aspects of habitability such as lighting and ventilation conditions, the specific conditions that an adapted dwelling must meet (for people with functional diversity/disability) or accommodation buildings (consisting of spaces for private use, in the form of accommodation units, and common services for collective use), as well as the conditions to be met in the event of a refurbishment of the dwellings and / or buildings in any of the above cases.

This regulation is the responsibility of the Regional Ministry with housing competencies, currently the Second Vice Presidency and Ministry of Housing and Bioclimatic Architecture. This Ministry already has a series of documents, regulations and initiatives that converge with the objectives and interests foreseen in the REDUCES project, so it is essential to keep them in mind in order to join efforts and synergies.

3.2. Other related policies and regulations

We consider the White paper on housing – Comunitat Valenciana (Conselleria de Vivienda Obras Públicas y Vertebración del Territorio, 2018) and the strategic plan Habitat 2030 (Vicepresidencia segunda y Consellería de Vivienda y Arquitectura Bioclimática, 2020) especially relevant due to their direct relationship with the political instrument of application in the Valencian Community.
The White paper on housing establishes the guidelines for the future housing policy of the Generalitat Valenciana. It is a long-term structural and strategic plan that includes a wide range of recommendations to address the housing problem. It has been conceived to foster social cohesion, housing justice and the sustainable occupation of the territory. It is structured with an analysis and diagnosis section, a strategic framework and a final proposal block with lines of action. The proposed lines of action are framed in 9 strategic axes (guaranteeing access to housing, promoting rental housing, mobilizing empty housing, promoting a social model of rehabilitation, promoting an inclusive environment, establishing a CE model in housing, orienting housing to the challenges of the future, improving the quality of housing and adapting management in the field of housing), among these, two should be highlighted:
• Establish a CE model in housing
• Orient housing to the challenges of the future,

in which actions linked to CE and the promotion of innovation through research and experimentation on new housing models are defined.

However, we can find underlying CE principles in most of the proposed axes and lines of action, such as mobilizing empty homes or promoting a social model of rehabilitation, strategies aligned with the principles of maintaining and prolonging useful life of an asset, or reuse before producing a new good.

"Habitat 2030" Strategic Plan is an operational instrument to guarantee the social function of housing in the Valencian Community and provide a quality public service that is comparable to European benchmarks. This is a ten-year plan in which the right to housing is understood as inseparable from the right to the city, therefore it postulates the right to a habitat. In addition, it is a participatory plan, starting from a base document an ambitious participation process started in collaboration with all the agents involved. Of the challenges posed, the Green Transition should be especially highlighted, in which the following objectives are proposed through the Green Transition and Circularity Pact on Habitat:

• Reduce the consumption of primary energy in conditions of comfort in the social housing stock.
• Promote final energy consumption from renewable energy sources, through the implementation of self-consumption systems.
• Promote the renaturalisation of urban spaces and their connection with natural environments.
• Promote refurbishment and renovation against new construction, urban regeneration and redensification (sustainable habitat).
• Adapt CE criteria to the real estate sector through innovative practices.
• Promotion of green employment through education and training.

It is essential to review the role of the Observatory of Habitat and Urban Segregation (Vicepresidencia segunda y Consellería de Vivienda y Arquitectura Bioclimática s.f.),hereinafter OHSU, established in February 2019. Its creation, provided for in Law 2/2017, of February 3, of the Generalitat by the Social Function of the Housing in the Valencian Community, serves the purpose of knowing, among other aspects, the situation in quantitative and qualitative terms of housing in general and public housing in particular, the territorial distribution of housing and the indicators determined in the public housing and urban regeneration policies of the Generalitat, dependent on the Ministry responsible for housing. Decree 9/2019, of February 1, creating the Habitat and Urban Segregation Observatory of the Valencian Community, establishes its main functions, among others that of advising on planning regulatory action in the area of housing and the city , and articulates its structure and composition, as well as the members (among them the IVE) that make up the plenary session of the Observatory (maximum organ of decision, control, planning, follow-up and supervision of the OHSU activity).

Finally, the Green Guide on environmental measures for public procurement in the building sector (Vicepresidencia Segunda y Conselleria de Vivienda y Arquitectura Bioclimática 2020) was draft and published recently. The environmental measures included in the guide are based on the ecological public procurement criteria developed by the European Commission and the Ecological Public Procurement Plan of the General State Administration, to which additional criteria are added. Thus, a first edition of the guide includes passive design measures for energy saving, active design measures for energy saving and water saving, as well as measures related to products, waste management and environmental certifications. However, the guide is intended to be a repository of environmental measures that are continuously updated, with the conviction that promoting the consideration

of sustainability criteria in public procurement, in addition to serving to obtain more environmentally friendly buildings, has a high exemplary value, while it can be a relevant element of influence in the market, encouraging the private sector towards new forms of production and more responsible consumption.

CONCLUSION

In general, we can consider that we are in an incipient state with regard to the implementation of a CE model in the Valencia region. Public administrations are making efforts to start introducing CE principles in the different policies (plans, strategies, or regulations), however a general, ambitious and joint action is lacking, which combines efforts from the different departments and allows the establishment of the proper priorities, while facilitating the creation of synergies, and thus maximizing results. We can also see how public administrations are working hard to improve green procurement and tendering processes, incorporating environmental and innovative criteria, in order to encourage the private sector to move towards more circular production and consumption models.

Otherwise there are many initiatives aimed at implementing CE criteria in practically all strategic economic sectors in the Valencian Community. In particular, in the sector of the built environment, we have seen that there are quite a lot of initiatives dealing with resource efficiency and recycling, and much less dealing with topics like the product life-extension or the use of renewable materials and resources. There are very few initiatives that address the circular economy as a whole, and practically none that focus on aspects such as promoting maximizing the use of products and resources, through sharing platforms, or promoting the change towards consumption models based on services. and not in buying goods.

The definition of a general framework, which coordinates and directs the efforts being made in the region from different private and public sectors, will allow also the identification of new niches or potential sectors to be developed in the Valencian Community, in the process of diversifying the economy.

As far as initiatives at municipal level are concerned, the integration of aspects related to the CE is even more scarce. It is worth highlighting the Declaration of Seville, an initiative launched by the Spanish Federation of Municipalities and Provinces, in which the signatory municipalities undertake to promote and encourage the CE in their territories. There are currently more than 230 municipalities throughout Spain, 24 of which are in the Valencian Community. Within this framework, the Local Strategy for the Circular Economy has been developed. This is a set of actions proposed as practical recommendations, aimed at Local Bodies, to facilitate the adoption and implementation of the principles of the CE in their areas of action, within their capacities and competences.

Finally, as far as citizenship and social awareness is concerned, it is still far from incorporating the criteria of the CE into their consumption habits. An effort must be made to communicate with citizens and convince them of the need to change mainly their way of consuming.

ACKNOWLEDGEMENTS

This paper is based on the work developed in the frame of REDUCES project (https://www.interregeurope.eu/reduces/). REDUCES Rethinking sustainable development in European regions by using circular economy business models, is an Interreg Europe project carried out by a transnational consortium of partners. The authors wish to express their gratitude to all the partners for their fruitful and active cooperation.

PAPER #7.18

NEXUS BETWEEN SUSTAINABLE BUILDINGS AND HUMAN HEALTH: A NEUROSCIENCE APPROACH

Madlen Simon[a], Ming Hu[a], Edward Bernat[a]
[a] University of Maryland, College Park, Maryland

ABSTRACT

The paper presents a preliminary result of a research project aiming to develop, test, and validate a data-driven approach using virtual reality (VR) and neurotechnology (EEG, etc.) for assessing the effect of sustainable building design features on occupants' emotional and cognitive functions - proxies for mental health and wellbeing. The project will provide technology-enabled, repeatable measures for quantifying the "soft" benefits of sustainable building design features, thus providing an economically viable and repeatable assessment model, pre-build.

Case studies have consistently demonstrated the potential for sustainable buildings to increase "soft" benefits of improved wellbeing and productivity via self-reported assessments. However, selfassessments are unreliable measures, as they are marred by participant biases and confounding variables. Current building impact evaluation tools that measure occupants' wellbeing and cognitive functions are user response surveys such as the health and work performance questionnaire (HPQ) and various building wellness surveys. Surveys have two main weaknesses. First, as there are many variables affecting an occupant's response to the built environment, such as familiarity with the space, time of day when the survey is conducted, and the ambient condition of the environment (temperature, smell, noise, etc.), confounding, non-design factors can be hard to disentangle, to control for, and interpret. Second, the survey response is an indirect measure of the environment, reliant on the user's opinions (perceived likes and dislikes) and cannot provide objective data about particular environments and features. What is needed are consistent, reliable, and physiologically based measures of mental health effects that capture human response to discrete architectural elements – especially in the prebuild, design phase.

This experimental research project offers a methodology to fill this gap, capturing real-time physiological response to user experience of sustainable built environments. This research provides a method for quantifying occupant wellbeing, thereby offering the potential to leverage change in mainstream design practices.

KEYWORDS

Sustainable architecture; virtual reality; neuroscience; event-related potential; design decision-making.

INTRODUCTION

Given that Americans spend about 87% of their time inside buildings,[1] the quality and design of buildings are important contributors to human wellbeing. The trend in "sustainable building" (SB) models, catalyzed by the founding of the Green Building Council in 1993, offers a unique opportunity to leverage not just beneficial environmental impacts but also occupancy wellbeing effects in the design and construction of new buildings. Case studies have consistently demonstrated the

[1] Zhang, Q., & Zhu, Y. (2012). Characterizing ultrafine particles and other air pollutants at five schools in South Texas. Indoor Air, 22(1), 33-42.

potential for sustainable buildings to increase "soft" benefits of improved wellbeing and productivity via self-reported assessments. However, self-assessments are unreliable measures, as they are marred by participant biases and confounding variables. Current building impact evaluation tools that measure occupants' wellbeing and cognitive functions are user response surveys such as the Health and Work Performance questionnaire (HPQ) and various building wellness surveys. Surveys have two main weaknesses. First, multiple variables affect an occupant's response to the built environment, such as familiarity with the space, time of day when the survey is conducted, and the ambient condition of the environment (temperature, smell, noise, etc.); these confounding, non-design factors can be hard to disentangle, control for, and interpret. Second, the survey response is an indirect measure of the environment, reliant on the user's opinions (perceived likes and dislikes) and cannot provide objective data about particular environments and features. What is needed are consistent, reliable, and physiologically based measures of mental health effects that capture human responses to discrete architectural elements – especially in the pre-build, design phase. In order to fill this
gap through the procurement of reliable, objective measurements, an innovative, data driven approach is needed. Conventional buildings (CB) – those that meet basic building and energy codes but do not prioritize sustainable design elements - provide an excellent control from which to expand research on the co-benefits of SBs to improve occupant mental health and wellbeing. Moreover, buildings are usually one-off projects. Anecdotal evidence and limited case studies are inadequate to leverage changes in mainstream design practices, in which decisions are primarily influenced by building economics and regulations. For systemic change to occur, occupant wellbeing, especially cognitive benefits, must be added into the SB base rating system. The objective of this project is to leverage VR and EEG technology to develop, test, and validate a data-driven neuroscience approach to assess the effect of sustainable built environments on occupants' emotional and cognitive functioning. Cognitive performance will be tested through both individual and group-based assessments across gender differences.

1. THEORETICAL FRAMEWORK AND SIGNIFICANCE

1.1. Theory and Background

Our methodological framework is based on the marriage of an event-related potential (ERP) neuroscience approach and cognitive architecture (CA) theory (see Figure 1). The use of EEG in built environment, cognitive science research, is growing rapidly due to its portability and flexibility in allowing test subjects to move around while immersed in a real environment. EEG is used to measure ERPs that demonstrate
brain activity directly related to a specific event (stimulus), such as the presentation of an image, word, or special visual environment. Unlike behavior studies used in the cognitive psychology approach, ERPs provide a continuous measurement of processing between a stimulus and response, very appropriate for studying a built environment design. Due to the complexity and multi-faceted
attributes of design, ERP continuous measurements have the potential to objectively elucidate what events (stimuli) are affected
by particular design feature manipulations. ERP measurement is typically more affordable than fMRI, and the long tradition of ERP/EEG research provides a solid basis

for application to design research.[2] CA was proposed by Herbert Simon, a pioneer in artificial intelligence, with the goal of creating programs that could solve problems across different domains, develop insights, adapt to new situations, and evaluate themselves.[3] It was initially employed in the fields of artificial intelligence and computational cognitive science.[4] CA refers to both a theory and method for regarding human cognition from a computational perspective. The theory is aligned with contemporary cognitive neuroscience, which generally considers the brain as having a modular organization, where individual modules interact to produce certain mental activities and emotions.[5] In 1973, Allen Newell called for the development of multiple, diverse CA styles instead of focusing on specific issues of understanding the human mind.[6] CA is considered by Langley (2017) as valuable in supporting research on cognitive science due to the complexity of humans' cognitive functions.[7] It has been used intensively in studying instructional design[8] to encourage learners to engage in conscious cognitive processing directly or indirectly relevant to the constructed curriculum.[8-9] CA has since been applied to research on 3D objects' perception,[10] spatial navigation,[10-11] and architectural design/design thinking.[12]

In this project, we rely on CA capabilities that can acquire and understand perception since cognition does not occur in isolation; an intelligent agent (person) exists in the context of a certain external environment that the agent (person) must sense, perceive, and interpret. If we can understand what perceptual knowledge is invoked by which sensors/stimuli in the environment, where and when to focus them, and what inferences are plausible, then a CA based model can be built to acquire and improve knowledge by learning from previous perceptual experience.[7]

1.2. Built Environment Parameters

In this study, we will use three sustainable built environment parameters as the design basis for testing our hypotheses: lighting, view and spatial quality. All three characteristics are required design elements in the most commonly accepted and utilized "Healthy Building" design guidelines and rating systems,
namely WELL and Living Building Challenge.
Lighting (LG) Indoor lighting quality and quantity have physical and psychological effects (visual and nonvisual effects) on building occupants. Physical impacts include visual strain, blurred vision and irritated eyes induced by insufficient light levels (illuminance), glare, and/or high contrast between indoor and outdoor light levels.[13] Studies have related visual discomfort and a decrease in reading accuracy[14-15] to the quality of lighting fixtures including the flickering of lights. People with special health conditions including children with autism have been given recommendations to avoid flickering lights or low-quality fixtures that emit sounds.[16] The primary characteristics of lighting shown to influence short term, psychological moods include light levels, light color, spectral distribution, and temporal patterns.[17-19] Long-term psychological and physiological effects from non-visual aspects of light emerged from circadian rhythms research.[20] Circadian rhythm controls natural sleep and awake patterns and requires external stimuli including the light-dark cycle.[21] Building artificial lighting systems and access to daylight both have large impacts on building occupants' circadian systems for two reasons. First, as the circadian system fundamentally underpins human physiology, extensive ripple effects are likely when disrupted. Second, as people spend the majority of their time indoors, it is highly likely that circadian systems are affected by indoor lighting conditions. Studies have suggested that some interior light levels are insufficient to appropriately regulate the circadian clock. Under such conditions, "biological darkness" and attendant effects predominate including fatigue and excessive sleepiness.[19] Researchers have postulated that insomnia and other sleep disorders might be treated by exposure to light at right time to reset the circadian rhythm.[22] Lighting can be both the

cause of and treatment for various health conditions.

View (VI): Views are directly related to the concept of biophilia design, coined in 1984 by Edward. O. Wilson to refer to the basic human need to affiliate with life and lifelike processes.[23] Per the attention restoration theory proposed by pioneering environmental psychologists Rachel and Stephen Kaplan,[24] nature has the ability to restore people's attention and release stress.[25] They demonstrated that people tend to prefer natural environments over built environments, and built environments with water, trees, and other vegetation more than built environments without such features.[26] Researchers continue to explore how building elements that represent, mimic, or provide access to nature environments impact restorative functions and wellbeing. Building views can be categorized in two types. The first is a direct visual connection to the outdoor natural environment.[27] An early study conducted by Roger Ulrich at Pennsylvania hospitals found the surgical patients assigned to rooms with windows looking out on a natural scene had shorter postoperative hospital stays.[28] The same restorative effects have been shown in other settings, including the home,[29] school[30] and office.[31] The second type is the visual connection to indoor natural elements, such as a green wall or water feature. In 2016, a research team studied classrooms in two elementary schools for 4 months. The results showed that children scored better on a test for selective attention in classrooms with green walls; there was no difference in the children's self-report on wellbeing.[32] Therefore, a view – either to nature or green elements within buildings - is an excellent and flexible design parameter for this research.

Spatial Quality (SP): Spatial quality and its impact on productivity and cognitive functioning belongs within the field of environmental psychology. Few studies have explored this area as spatial characteristics are difficult to define and measure. Some studies have investigated the impact of a building interior's layout (floor plan) with varied results. Early studies by Hedge (1982)[33] and Sundstrom et al. (1980)[34] found worker dissatisfaction correlated to increased spatial openness. Brennan et al (2002) conducted a longitudinal field study to examine workers' satisfaction and productivity before and after relocation from traditional (enclosed) offices to open offices. They found that workers were less satisfied in terms of increased disturbances and decreased privacy following the move; the dissatisfaction persisted after an adjustment period.[35] Other research showed layout-scale spatial measures are better predicators of how well occupants rate the capacity of a work environment to support collaboration, in comparison with workstation-scale measures.[36] A U.S national survey study in 2003 demonstrated that attractive physical school environments

(middle and high schools) were associated with fewer problematic and risky student behaviors, whereas the less attractive physical environments were not.[37] However, this study only differentiated attractiveness from cleanness, and did not define attractiveness. Subsequent researchers have postulated that a school's multi-dimensional spatial qualities (physical environment design) are imbued with different meanings and messages for students. An attractive, clean and orderly space comprises a high spatial quality and conveys to students the message that this is a place where
learning and growth are both valued and supported [Kumar et al 2003]. At the neighborhood scale, a Netherlands study showed that neighborhood attractiveness positively added to residents' reports on life satisfaction and wellbeing.[38] This research suggests that a neighborhood's attractiveness may be associated to social status, and therefore may contribute to social safety – a wellbeing benefit.[39] The same Dutch study showed that other spatially-mediated improvements such as traffic convenience and facility accessibility did not significantly affect life satisfaction. These findings indicate the need for a deeper understanding of the relationship between spatial quality and occupant cognitive function, performance and productivity.

2. EXPERIMENT

In 2018 and 2019, the research team conducted pilot VR environment tests using the three SB parameters (lighting, view, spatial quality) with 36 participants. Two different models of the same, three-dimensional virtual building were built by using Autodesk Revit software to construct sustainable (SB) and nonsustainable
(CB) designs. These were then rendered, using Unreal Software, into two "real time" VR buildings / designs for use in the experiment. The simulated environment consisted of a two story building composed of four different spaces: (1) public: entry lobby / open staircase, (2) semi-public: collaboration space, conference room, open kitchen, (3) semi-private: fitness center, conference room in open
office, (4) private: individual working space. When the participants were in the VR environment, a "preset walk-through" allowed them to get comfortable with the equipment and the experience. Figure 2 illustrates the floor plan with walk-through route, and the

location where the participants stopped and looked around in the VR environment. These stop locations were preset. They first entered through the building lobby, then walked up to the secondfloor open office area through a large open staircase. During the two-floor tour, they encountered the fitness center, open kitchen, collaboration space, and conference rooms. The differences in the 4 space types between the SB VR environment and control CB VR environment are described in Table 1 and illustrated in Figure 3.

3. PRELIMINARY RESULTS

3.1. Experiment Procedure

A three-step tasking method was developed for measuring experiences of both buildings, employing video, still images, and a guided VR tour. 45 still images, a 5-minute video, and a guided VR tour were created for SB and CB respectively; test subjects spend 25 minutes in each building. With sensor placements, task practice, and acclimation to the VR, one subject testing took about two hours.

3.2. Preliminary Data: Neurophysiological Measures and Cognitive Tasks

In this section we introduce the time-frequency (TF) signal processing methods central to the proposed work. These are introduced in the context of two of the tasks (gambling feedback and go/no-go), representing the validation of the proposed methods and tasks. Preliminary data from our application of these measures to data from the virtual environments will be presented further below.

3.3. TF measures of theta and delta: indexing salience and complex elaborative processing.

Our preliminary work has shown that TF approaches separate overlapping processes during conventional ERP components. We have developed a TF approach[40] that differentiates medial-frontal (MF) theta (3-7 Hz) and centro-parietal delta (0-3 Hz) contributions to ERP components such as the P3[41-42], feedback negativity (FN), error-related negativity (ERN)[37-43], and the No-go.[44] shows separation of theta and delta frequency during the FN[45-47] gambling task and Go/No-go N2.[48] We have assessed the sensitivity of separable theta and delta measures to mental health outcome measures, where we found that theta during the ERN [43]and delta during the FN[42] were sensitive to disinhibitory behavior problems. *This work indicates that the neurodynamics of many common ERP measures can be understood as a mixture of separate processes occurring simultaneously in theta and delta frequency ranges that are obscured in the unfiltered signal. These measures are sensitive to cognitive and affective processes relevant to mental health and task performance.*

3.4. TF Interchannel Phase Synchrony (ICPS): indexing Functional Connectivity.

We have validated a new measure of functional connectivity for EEG neuroimaging data based on TF interchannel phase-synchrony (ICPS),[49] and have demonstrated that it is sensitive to medial-frontal to lateral PFC functional integration underlying cognitive control processes associated with the error-related negativity (ERN) [50-55] as well as the No-go N2[55] and FN [46,57]. An example of No-go N2 and FN bivariate ICPS (with FCz as a seed-reference, cf. ACC) is given in Figure 5. Here correspondence between these measures in the theta range is presented, with topographical maps displaying significance (white indicates $p < .01$). For ICPS, significant phase-synchrony with lateral-frontal, motor, and occipital areas are apparent. We recently tested the sensitivity of the ICPS measure to INT-relevant worry indexed by the Penn State Worry Questionnaire (PSWQ) during the ERN in a sample of undergraduate students (N=77). Using path analyses, we found that ERN theta amplitude was positively related to PSWQ ($r = .26$, $p < .05$), supporting the view that worry represents overactive salience processing, while, ERN theta ICPS between medial and lateral PFC regions was negatively related to PSWQ ($r = -.31$, $p < .01$), supporting the view that control processing was simultaneously diminished for worriers. Importantly, analyses confirmed that these relationships with PSWQ were independent, separable, processes. Finally, the path analysis supported the inference that worry indirectly influences post-error behavior via ICPS (accuracy and RT), rather than amplitude. Specifically, worry is associated with faster post-error RT and lower post-error accuracy through its relationship with reduced TF-ICPS. The indirect path between the TF-amplitude and post-error behavior through TF-ICPS was significant (Sobel's $t=2.43$, $p=.01$) indicating that theta amplitude predicts behavior primarily through theta ICPS. *Together, this work indicates that our ICPS measure of functional connectivity appropriately indexes integration during the proposed tasks, and is sensitive to worry, a primary component of stress.*

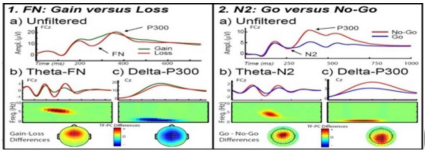

Figure 4. Theta/Delta separate processes

Figure 5. Measures of theta amplitude and ICPS

3.5. Preliminary Interpretation: CB vs. SB

We collected preliminary neurophysiological data based on CB and SB versions of the building detailed above (N=36) and applied the proposed TF amplitude and ICPS measures. For the initial data, we presented a movie from a walkthrough of the building, to record continuous EEG, and still pictures taken from the movie, to record ERP data. Results are presented from the still pictures and movie, based on the TF amplitude and ICPS approaches. TF Amplitude results for the SB and CB movies indicated significant increases in theta (presented in Figure 6), suggesting greater engagement in the SB environment, but not other bands. Still picture results are presented in Figure 7 and demonstrate robust differences between the SB and CB. The top row contains traditional time-domain measures. The waveform plot depicts overall activity in the first and second 500 ms blocks after picture presentation. The topomaps to the right depict the amplitude differences (color, where red indicates increases and blue decreases) and

the associated significance (where white indicates p < .01, and black indicates p > .10, uncorrected). Significantly greater activity in bilateral occipital regions, as well decreases in frontal regions, can be readily observed. The TF results decompose this activity, as well as index activity not observable in the time-domain. Next, the TF results indicate significant differences between SB and CB for delta (0-3 Hz), theta (3-7 Hz), and alpha (8-12 Hz) frequency bands. Delta effects in the early block (0-500 ms) primarily index the increases bilateral occipital activation observed in the time-domain, consistent with the fact that delta activity generally contains the largest amplitude and is thus more strongly reflected in time-domain measures. In the later block (500-1000 ms), delta shows significant centro-parietal decreases. Together, the early increases and later decreases are consistent with a strong early response to the SB pictures, dominated by visual simulation, which resolves more quickly than the CB in the later block. Next, theta activity in the early block shows increases in bilateral occipital activity for SB relative to CB, concomitant with occipital increases in delta, as well as centro-parietal increases. Lateral-frontal increases for SB pictures are also evident, consistent with engagement of control regions in lateral prefrontal regions. In the second block only the increases in centro-parietal areas are maintained. Finally, for alpha, a decrease in bilateral occipital areas is readily observed, consistent with greater engagement of the visual system, consistent with the increased activation observed in delta (parietal-occipital alpha indexes an inhibitory processes, such that decreases indicate increased activity in that area). We additionally assessed alpha asymmetry in the 500-1000 ms still image viewing task, where we predicted greater relative right-hemisphere activation, indicating greater approach tendency. Results provided some support for this inference, with greater relative right-hemisphere activation for overall alpha at a trend level (8-13 Hz; z = 1.74. p = .082, r = .145), as well as upper alpha sub-band (11-13 Hz; z = 2.11. p = .034, r = .176). *Preliminary results indicate ERP techniques represent a robust index of processing difference in the SB versus CB built environment, providing novel information about mechanisms underlying those differences to explore herein.*

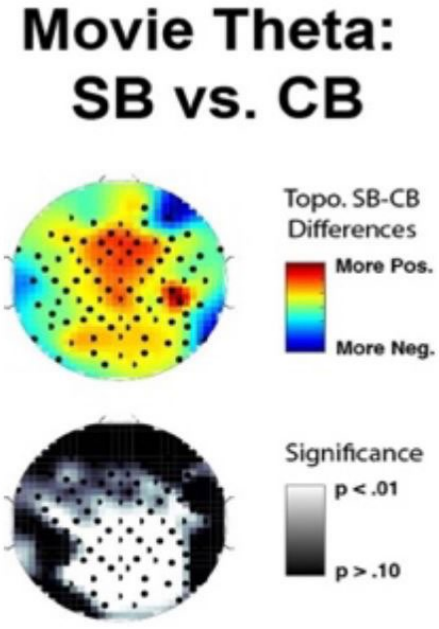

Figure 6. Movie amplitude

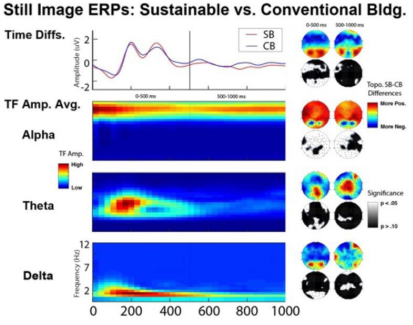

Figure 7. Still image amplitude.

Functional connectivity was indexed by ICPS at beta 2 (20-30 Hz), beta 1 (13-20 Hz), as well as alpha, theta, and delta as assessed for amplitude. Significant ($p < .05$, uncorrected) bivariate ICPS measures were computed from 8 seed regions (5 in frontal regions, and 3 in occipital regions), for both the movies and image event-related data. These results are presented in Figure 8. We assessed these seed regions, beyond just a priori connectivity between one medial-frontal seed and 2 lateral sites (as in our preliminary work above), to have a more broad assessment of engagement of frontal areas, anticipated increases in occipital processing related to engagement with the stimuli, as well as long-range connectivity between these regions. Further, because there is little work in this area, there were fewer published findings to guide our hypotheses. First, for the movies, results for delta, theta, and alpha demonstrated parallels to the still image amplitude effects. That is, both delta and theta showed increases, while alpha demonstrated decreases. This is also consistent with the increase in theta observed in the movie amplitude data. These results suggest that the amplitude effects in the still images may index functional integration occurring during watching the continuous movie of the SB relative to the CB environments. Results in higher frequency beta range were in opposite directions, with increases for SB in beta 2 and decreases for beta 1, relative to CB. This is consistent with emerging work suggesting beta 2 can index reward processing[58-61] (increased for SB in these results) and increases in beta 1 can be related to loss processing[62-65] (increased for CB in these results). Results for the still images were more complicated and difficult to interpret, although the number of significant results suggest this approach was sensitive to differential processing, both within and between frontal and occipital regions, associated with SB and CB during still image processing. While these findings must be taken tentatively, due to the small N, and associated lack of statistical power, overall effects suggest the feasibility of detecting functional connectivity associated with viewing SB relative to SB environments. *Preliminary results demonstrate sensitivity to differences in functional connectivity within and between frontal and occipital areas central to how people perceive and engage with the built environment.*

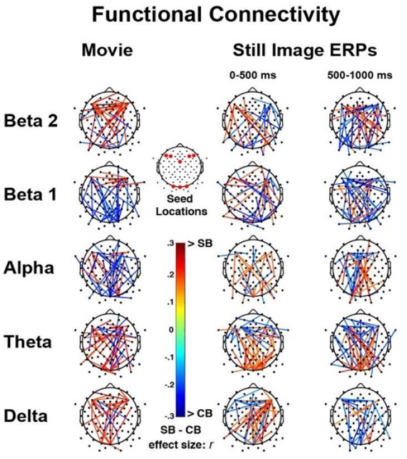

Figure 8. Functional connectivity: significant bivariate ICPS measures (p<.05, uncorrected), using 5 frontal and 3 occipital regions as seed references

CONCLUSION

The mechanisms underpinning how the built environment affects mental health and cognitive functioning are largely unexplored due to the complexity of built environment, and the difficulty in quantifying psychological responses. A neuroscientific approach has the capacity to bridge this gap. This project developed and tested a neuroimaging experimental protocol, combined with VR technology, as a quantitative, repeatable framework that can be readily adopted by researchers in a wide variety of social science and design fields. Our approach provides a unique new utility to three (separately) validated
methodologies by combining (1) EEG with an emerging design technology, (2) VR to overcome the dual problems of confounding variables and participant bias during the measurement of elicited user responses to SB features in real time. VR allows three-dimensional, systematic design manipulations that are prohibitively expensive in real environments and EEG offers validated inferences regarding cognitive and affective processing. Our approach combines (3) continuous EEG approaches with neuroimaging to understand occupants' emotional responses. The in-depth understanding of mechanisms driving occupant behavioral differences between SB and CB virtual environments will provide designers and engineers with evidence to change, modify and propose new design solutions – pre-build. In the future, the integration of neuroscientific validated evidence in the design process may lead to a novel and impactful design framework for building industry adoption.

PAPER #7.19

HOW MUCH DOES ZERO ENERGY BUILDING COST?

Ming Hu[a]
[a] University of Maryland, College Park, MD

ABSTRACT

Developers, building owners, and design teams often point to initial capital costs as the
primary obstacle hindering the uptake of net-zero buildings. In-depth research and an understanding of whether net-zero buildings cost more to design and construct are still scattered and non-systemic. Accordingly, this study provides the first comprehensive investigation into actual net-zero building construction costs in the United States, based on qualitative and quantitative research. The aims of this research are to: (1) provide a comprehensive survey of the existing body of literature to aggregate the findings and identify the consensus and pattern, (2) compare the results and analyze the evidence with a focus on quantitative studies, and (3) conduct a quantitative comparative analysis of twelve built zero energy buildings (ZEB) in order to understand whether there is enough evidence of cost differences between ZEB, conventional building (CB) and green building (GB). Statistical tests were performed, with the results showing no significant differences between actual ZEB costs and modeled CB costs. Further details investigated the cost difference between actual ZEB and modeled GB. The findings of this research provide initial detailed insights into net-zero building costs in the United States, which may benefit the promotion of ZEB practices.

KEYWORDS

Zero energy building; conventional building; construction cost; modeled cost.

INTRODUCTION

The building industry contributes significantly to global CO2 emissions as well as energy consumption. Global energy consumption is assumed to increase by 33% from 2010 to 2030 (Kim et al. 2014, Abdelaziz et al. 2011). The United Nations' Sustainable Buildings and Construction Programme published a report suggesting that building and construction sectors account for 40% of global energy use and 30% of energy-related GHG emissions. During 2016, the United States' building sector consumed 40% of primary energy, based on the U.S. Energy Information Administration's statics (EIA 2018). Primary energy, deriving mainly from fossil fuels, while limited, is a major contributor to CO2 emissions, which are rising globally at a rate of more than 2% per year (Kelso 2012). Consequently, building green is one of the most effective strategies for overall energy consumption reduction and CO2 emissions reductions. However, design teams and building owners often cite the incremental initial costs of green (energy efficient) building as significant barriers to building high-performance buildings with the ultimate goal of achieving net-zero energy. So far, there has been a large amount of research focusing on the benefits of green building (GB) for users, clients, and society. (Liu et al.) estimated that GB could create incremental economic benefits by saving energy and improving the environment (Eichholtz et al. 2010) while (Eihholtz et al.) pointed out how the green label affects the market rents and values of commercial space, potentially leading to the high resale value of a building (Gabay et

al. 2014). However, only a small portfolio of studies have investigated the cost obstacles; regarding costs related particularly to net-zero building, there is very limited literature and reports to date. Meanwhile, despite the widespread perception of GB as expensive, the empirical studies and evidence needed to support this claim are inadequate, and the issue of a high green-cost premium is still debatable. It is foreseeable, though, that the cost concern could become one of the major obstacles to the promotion of zero energy building (ZEB). Therefore, a study of ZEB as a separate building type independent from GB will provide an opportunity to investigate the differences between ZEB and GB and the related cost indications.

1.RESEARCH METHODOLOGY

1.1. Cost definition

This research project focuses on the construction cost of ZEB since the perception of ZEB having expensive initial costs has been recognized as one of the critical obstacles to promoting net-zero energy building, and they are paid by the developer and investors. The construction costs of building include direct (hard) costs and indirect (soft) costs. Direct costs are related to cost materials, labor, construction equipment, energy, water, and other costs directly related to the activities of constructing a building. Indirect costs include costs related to the design, commission, permitting fee, documentation fees, and other legal fees (Mapp et al. 2011; Yudelson 2010, Khoshbakht et al. 2017). The post-construction costs comprise the building operation costs: energy, water, maintenance, repair, and management (Khoshbakht et al. 2017). Some researchers have indicated that general misunderstandings of construction costs for building green stems from individuals having no experience in the construction of green and energy-efficient buildings (Shrestha & Pushpala 2012). The perceptions about the higher costs of GB has hindered the advancement of more energy-efficient building and construction.

1.2. Cost estimation and analysis method

There are several methods and techniques used for cost estimation in the building industry, including the traditional statistical analysis of detailed itemized costs, factor analysis of construction activities (Kaming et al. 1997, Ben-Arieh & Qian 2003) time-dependent cost trend projection, index number cost estimation
(Ashworth & Perera 2015), expert systems estimation (Brook 2016),integrated analysis of multi-objectives (Pettang et al. 1997, Zhang et al. 1998, Hwang 2016). and BIM and ontology-based cost estimation (Lee et al. 2014). In the building industry, the traditional statistical analysis of detailed itemized costs is the wider used method due to its simplicity and availability of multiple itemized cost database. The other methods are presented and analyzed in research and academic settings, and their application in the field and actual projects are very limited (Valentini et al. 2017). Since the primary goal of this research is to analyze the actual net-zero building cost and understand the perceptions from the field, the first traditional cost estimation method was selected. Two commercially available itemized cost databases are selected and used. The cost analysis of sustainable building can be categorized into two groups: paired comparison and unpaired comparison. An unpaired building cost comparison is a statistical analysis method based on a comparison of actual or simulated costs of unpaired GBs and conventional buildings (Khoshbakht et al. 2017). A paired building cost comparison involves comparing the costs of two identical buildings for the cost of conventional upgrades versus green upgrades (Hwang 2016). In this research project, paired comparison is used to compare the

costs of simulated net-zero building, GB, and conventional building. Two construction cost databases were selected and compared: the 2017 National Building Cost Manual (NBCM) and RSMeans's Square Foot Costs Book (RSFCB).

1.3. Case studies selection

Three major programs in the United States have influenced the promotion of green building and net zero building practices, and they all have rating systems or tools to measure and quantify building performance. These three programs are (1) LEED, managed by the U.S Green Building Council, which is a private nonprofit organization; (2) the Energy Star Label, jointly managed by Department of energy (DOE) and Environment Protection Agency (EPA); and (3) the zero energy building certification organized by the International Living Future Institute (ILFI). All three are volunteer programs.The largest database of zero net energy (ZEB) building is the online database that was created, organized, and managed by the New Building Institute (NBI).[1] In May 2017, the ILFI and NBI announced a partnership to track and certify ZEB building to drive a broader market adoption. Therefore, in this research project, that database was selected, and education buildings were chosen as the study types. Altogether, there are thirty-nine new constructed education buildings and four renovated education buildings, which is the largest building type group in the current database. The projects have a square footage ranging from 1,528 ft^2 (141 m2) to 286,212 ft^2 (26,590 m^2) and an energy use intensity (EUI) of 50 $kwh/m^2/yr$ to of 432 kwh/m2/yr. The author then matched the addresses of the buildings included in the database with those in the LEED project database to acquire additional information, such as energy consumption reduction, water conservation, and recycled and reused materials. The match yielded twelve buildings for which the construction cost, area, energy efficiency, water efficiency, and building mechanical system characteristics could be identified. Table 1 provides a breakdown of these projects by building system and costs. The selected buildings were net-zero energy buildings that consider the following two aspects: electrical energy production and thermal energy production (heating, cooling and DHW).

There are three steps in cost estimation: (1) create an itemized unit cost database based on RSMeans's book and the National Building Cost Manual (NBCM); (2) build a three-dimensional building information model (BIM) based on verified ZEB construction information and export the building material and system information to Excel format; and (3) used the database from (1) and building information from (2) to estimate the cost of CB and GB.

- Step 1: Cost estimation data collection

In this research project, a traditional itemized cost estimation method was used. The researcher initially sought to collect actual cost data of CBs or GBs with a compatible size and use it as a control group for comparison. However, since most building owners were reluctant to share cost information, this research was redesigned to compare actual net-zero building costs with modeled costs of CBs and GBs. Two construction cost databases were selected and compared: the 2017 National Building Cost Manual (NBCM) and RSMeans's Square Foot Costs Book (RSFCB).

- Steps 2 & 3: Itemized cost calculation using BIM model Based on available data from building floor plans, sections, elevations, detail drawings, and project descriptions, first, three-dimensional virtual models were created in Autodesk Revit for each case building, based on the information provided by building owners or found online (Hu et al.

[1] The New Buildings Institute (NBI) is a non-profit organization driving better energy performance in commercial buildings.

Project	City State	Use	Building Area (ft^2)	EUI (kwh/ m^2)	Cost ($)	Year	Net-Zero Energy Feature

Table 1. Case project details

2017). All building information was input in three-dimensional virtual models in a BIM environment so that users could extract and organize the cost-related information easily. The three-dimensional models include all primary building materials and systems to reflect the actual conditions of the case buildings. Some advanced materials and building systems, which are not included in the existing Revit library, were created and manually input in the models. Then, a material schedule was created within the Revit model, transferring three-dimensional data of materials into two-dimensional, quantitative itemized numbers, including volume, weight, dimensions, layers, and assemblies (Hu 2017). Afterward, the schedules were exported to an Excel-format file and used as a cost estimation sheet for calculating the CB and GB with the same area, building construction, material assemblies, and systems as the net-zero building. As shown in table 5, the primary categories included in the calculation were direct costs and indirect costs. The direct costs included the building substructure system (foundation), floor and roof system, exterior walls and windows/doors, interior walls and finish, ceilings, restroom fixtures and plumbing system, HVAC systems,
and vertical transportation system. The indirect costs included the designers' (architect and engineer) fee and contractors' fee. Instead of a rough per area cost estimation, which is often found in cost analysis in GB, in this study, the author conducted a detailed breakdown cost estimation by utilizing the advanced building information modeling software Autodesk Revit. In conventional methods, a cost estimator digitizes the architect's paper drawings or imports two-dimensional information of the building (data) into a cost estimation package. In either of these methods, human error could occur easily, and inaccuracies could propagate from the original data entry to the final cost number. Autodesk Revit, as a building information modeling (BIM) tool, allows the author to automate the task of quantification and then extract and transfer the data to an Excel format for a final cost estimation checkup.

2. STATISTICAL ANALYSIS

Null analysis is appropriate for this research project. From the literature review and ZEB actual cost information, there is no clear indication that ZEB has a higher premium than the national average for conventional building. Therefore, before analyzing the causes of a premium cost, understanding whether there is a cost difference is more important. This was conducted to determine if ZEB costs were indeed significantly different from the CB and GB. The Wilcoxon signed-rank test is commonly used to test for a difference in a paired observation, and a sign test is often used to test the null hypothesis.

The analysis considers two null hypotheses:
• H01:There is no significant cost difference between ZEB and CB.
• H02 There is no significance cost difference between ZEB and GB.
The two alternative hypotheses are:
• Ha1:There is significant cost difference between ZEB and CB.
• Ha2 There is significance cost difference between ZEB and GB.

Descriptive results
The results from the Wilcoxon matched pairs signed-rank test for ZEB, compared to CB, are illustrated in table 2 and the tests for ZEB and GB are shown in table 3. The overall results of the two null hypotheses are provided in table 7. The equation used to obtain the statistic W is:

$$W = \sum_{i=0}^{n\prime} R_i^{(+)},$$

where n' is the actual sample size, Ri is rank, and W is the Wilcoxon test score.

For null hypothesis number 1(H01), the model costs of six CB are higher than the actual ZEB cost, and the rest six CBs costs are lower than the actual ZEB cost. The Wilcoxon test score (W), 35, is higher than the critical value used for a two-tier test of 14. Based on this result, we could not reject null hypothesis 1(H01), instead, we should reject the alternative hypothesis (Ha1). As conclusion, we consider there is no difference between the actual ZEB and modeled CB building cost, based on RSFCB and NBCM datasets. For null hypothesis number 2 (H02), there are model costs of ten GBs that are higher than the actual ZEB cost, and model costs of two GBs that are lower than the actual cost. The Wilcoxon test score (W), 11, is less than the critical value used for a two-tier test of 14. Based on this result, we could reject null hypothesis 2, and we conclude alternative hypothesis (Ha1) can be supported: there is difference between the actual ZEB cost and modeled GB cost, based on the RSFCB dataset.

3. FINDINGS

3.1. ZEB is not more expensive than CB

The first important findings is there is no significant cost difference between actual ZEB cost and modeled CBs cost. Regarding cost, 33.3% of ZEBs are equal to or 2% more expensive than CB, 33.3% of ZEBs cost 10–16% less than CBs, 16.7% of ZEBs cost 45–48% less than CB, and only 16.7% of ZEBs cost 45–68% more than CBs (refer to table 5).

3.2. Reasoning for higher modeled GBs cost than actual ZEBs cost

The rejection of null hypothesis 2 suggests a cost difference between the actual ZEBs and modeled GBs, so the author further investigated the cost difference between the actual ZEBs and modeled GBs, and which factors have correlation to the cost difference. The factors investigated are: location, year of completion, area and building types. Pearson correlation coefficient (r) was used to study the correlations factors and cost difference between ZEB and GB. Pearson's r

measures the linear relationship between two level variables. Table 6 shows the r value of those correlations. There is positive relation between the year of completion, total area of the building to the cost differences, and negative relation between building types, location to the cost differences. And among the four factors, building area (0.966) has the strongest correlation to the cost differences, year of completion has the weakest correlation to cost differences.

Building factors	Pearson correlation coefficient (r) to cost differences
Building Type	-0.536833324
Location	-0.612306625
Year of Completion	0.274831032
Building Area (size)	0.966356149

Table 6. Correlation between cost difference (ZEB to GB) and building factors

3.3. Building size as the primary factor affecting the unit (square footage) cost of the building

Next, author further examined the relationship between cost differences and building size(area). Figure 2 shows that there is some negative correlation between the construction cost and building size. Overall, buildings with a lower unit cost show a larger difference between the actual cost and modeled cost whereas a building with a higher unit cost shows less difference.

CONCLUSION

This study provides the first in-depth investigation into actual ZEB costs in the United States based on detailed information. With higher initial costs being perceived as major barriers to the uptake of ZEB, the findings from this research project could be critical to further understanding whether ZEB cost more. Based on the comparison of actual and modeled costs of twelve built and verified ZEBs, it can be
concluded that, in general, there is no significance between actual ZEB costs and modeled CB costs. Although the data shows several net-zero buildings as having substantially higher costs than the modeled costs, a sizable portion of net-zero buildings have been found to be below the modeled cost. Interestingly, the study also shows a significant difference between actual ZEB costs and modeled GB costs. The magnitude of difference between those two are primarily affected by the size of the building.
This study has several limitations as well. Firstly, future research using data with different building types is needed to verify these

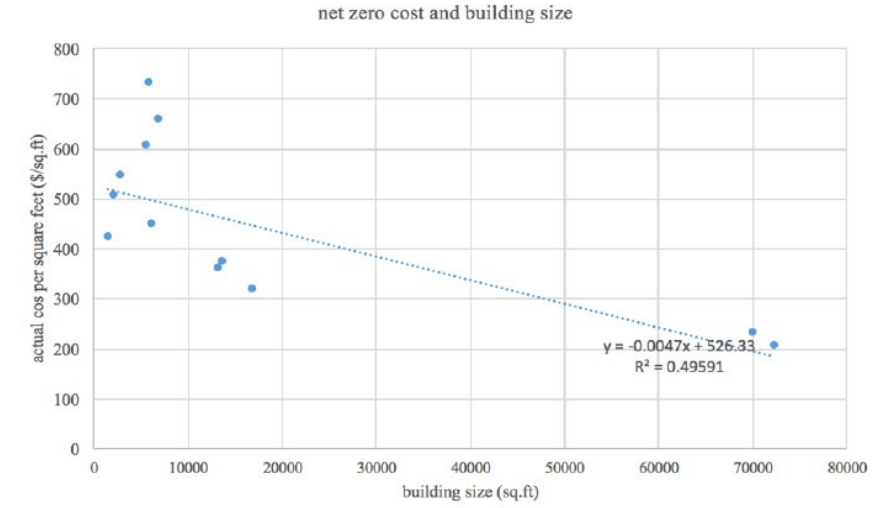

Figure 2. Correlation between cost and building size

findings and address the issue of variance within the building subgroups. Other building types should also be investigated, including commercial office and residential buildings. Secondly, out of the twelve case projects, four are more than ten years old. More recent projects and data should be used in future studies. The third limitation in this study was the small dataset of only twelve buildings; ideally, at least thirty buildings should be studied so that parametric statistical testing can be conducted, leading to a more detailed analysis. Furthermore, the collection of actual cost data from other sizable markets, such as the United Kingdom and EU member countries, could result in a considerably larger ZEB cost dataset 34 that would enable a more robust study and analysis.

PAPER #7.20

BETWEEN RESEARCH AND TEACHING: IDENTIFYING NEW COMPETENCIES FOR HEALTHY CITIES

Francesca Giofrè[a], Mohamed Edeisy[a]
[a] Department of Architecture and Design, Sapienza University of Rome, Rome, Italy

ABSTRACT

Healthy Cities is one of the central themes addressed in the Sustainable Development Goals. The World Health Organization's new Urban Health Initiative creates a paradigm shift in health systems approaches by focusing on the urban environment as a prerequisite for healthy lifestyles - and disease prevention. In Europe, the Zagreb declaration pointed out its attention to strengthen and champion action on health through healthy cities networks. Architects and engineers play a strategic role in building this future and activating actions in key development sectors, like housing and transport, as well as in the settings where people live and work. This requires new professional figures with the hard and soft skills that stimulate urban transformation for healthier built environments.
The paper discusses a methodological approach to identify the competencies to be acquired by future practitioners. It is developed within an ongoing Erasmus+ project[1] that represents the contextual field for testing the method in three Bosnian Universities. The article describes the methodology and its application. It starts with designing analysis' grids to evaluate how the topic is currently addressed, and it builds questionnaires to evaluate the students' awareness. Moreover, the research investigates stakeholders through organized seminars and surveys to understand the labor market and social needs. The paper suggests a strategy for setting up new courses for future architects, urban planners, and engineers, experts of the healthy urban environment. Testing the method in the Bosnian context, one of the main indications is the importance of innovative teaching methodologies integrated with the use of practical experience and laboratories. The method proposed is replicable for curriculum development in Higher Education, and it highlights how the research is a fundamental base for designing and teaching academic courses.

KEYWORDS

Healthy city; architecture; engineering; competencies; higher dducation.

INTRODUCTION

Healthy City started to be a crucial topic in the last twenty years, because of the huge number of inhabitants in the urban area. All over the world statistical data confirms the growing trend: in 2018 55% of the world population lives in urban areas, and according to the last projection it is increasing to 68% by 2050. Europe is the continent with a high density of urban population, 74% in 2018 (UN 2019), despite its low rate fertility, population decline - it will decrease from 13 percent to 9 percent between 2018 and 2050 - and significant diversity in the urbanization levels of its countries.

[1] The Healthy URBan Environment Developing Higher Education in Architecture and Construction in Bosnia and Herzegovina - HURBE - is a CBHE project, co-funded by the Erasmus plus programme of the EU Union (2018-2021). The coordinators of each Universities are: Francesca Giofrè (lead coordinator), Sapienza University of Rome, Faculty of Architecture, Department Architecture and Design; Vesna Mikić, University of Zagreb, Faculty of Architecture; Milena Tasheva-Petrova, University of Architecture, Civil Engineering and Geodesy; Maja Popovac, Dzemal Bijedic University of Mostar; Senaida Halilović-Terzić, University of Sarajevo; Samir Lemeš, University of Zenica.

This scenario is having a strong impact in the city, in terms of consumption of resources, on the system of spaces, on the demand for services, on the health, and on social relations. At the global level among the Sustainable Development Goals, the 11th goal "Make cities and human settlements inclusive, safe, resilient and sustainable" stresses the importance of the planning and managing processes of the city. These processes can produce a significant difference and have effects on the health of their residents (Lancet 2012, 3), as confirmed by several scientific studies in the last 150 years (GNRUHE 2010). The European Healthy Cities Network launched in 1986 by the World Health Organization (WHO-EHCN), and now at its VI phases, plays a strategic role in promoting policy and plan in European urban areas, positioning in its core the notion of the 'health' of the inhabitants.

Health, according to the evolution of the concept, is defined as "a state of complete physical, mental, and social well-being" (WHO 1948) "and not merely the absence of disease or infirmity" (WHO 2005); it is a positive concept and it is a human right. Moreover, according to the Meikirch Model health "is a dynamic state of well-being emergent from conducive interactions between an individual's potentials, life's demands, and social and environmental determinants. Health results throughout the life course when an individual's potentials – and social and environmental determinants – suffice to respond satisfactorily to the demands of life. Life's demands can be physiological, psychosocial, or environmental and vary across individuals and contexts but, in every case, unsatisfactory responses lead to disease" (Bircher and Hahn 2017). In fact, the state of human health would be conditioned by 50% of their behaviors and lifestyles, but also environmental factors (20%), genetic factors (20%), and health care (10%) (Amara, Bodenhorn and Cain 2003).

The environmental determinants include the whole biosphere, in other words, the environment people need for their daily life as nutrition, recreation, work, move, etc.; the environment is made by water, air, soil, housing, buildings, streets, routes, greenery, and so on. In general term healthy city is defined by the Health Promotion Glossary the "one that is continually creating and improving those physical and social environments and expanding those community resources which enable people to mutually support each other in performing all the functions of life and developing to their maximum potential."(WHO 1998).

Analyzing the documents produced by the European Healthy Cities Network and in particular the Zagreb Declaration (WHO-EHCN 2003, 2009) it is possible to define the intervention areas for urban planners, architects, engineers, but not only for these professionals. These documents identified their space of action in creating and design the healthy urban environment, aiming to offer "a physical and built environment that supports health, recreation and well-being, safety, social interaction, easy mobility, a sense of pride and cultural identity and that is accessible to the needs of all its citizens" (WHO-EHCN 2003). The related issues that integrate the concept of health, and that interest those experts are: urban planning; housing and regeneration; transport; climate change and public emergencies; safety and security; exposure to noise and pollution; urban design and creativity and livability (WHO-EHCN 2009, 5-6).

The themes are several referring to disciplines involved and to various scales of interventions (citywide, neighborhood and local environment), and they are all strictly connected and influence each other. Furthermore, the cities are "the example par excellence of complex systems: emergent, far from equilibrium, requiring enormous energies to maintain themselves, displaying patterns of inequality and saturated flow systems

that use capacity in what appear to be barely sustainable but paradoxically resilient networks" (Hancock and Duhl 1986, 1988), and the scholars are still on researching a proper methodology for assessing the impact and outcome of actions to build a healthy city. There is a principle of interdependence between the various policies that can no longer be neglected, and the 'construction' of the Health City represents a long-term urban and territorial planning process (Giofrè and Đukanović, 2017).

In this framework, Sapienza University of Rome, Faculty of Architecture, is leading the European Project in the area of Capacity Building in Higher Education, co-founded by the Erasmus+ programme, titled 'HURBE - Healthy URBan Environment Developing Higher Education in Architecture and Construction in Bosnia and Herzegovina" with the Universities of Architecture and Civil Engineering of Zagreb, Sofia, Sarajevo, Zenica, and Mostar. Among the general aims of the project, there is to improve the quality of higher education in the universities of Bosnia and Herzegovina (BiH) by focusing on curriculum development in the topic of healthy urban environment. The project is still ongoing (2019-2021); it is the field of experimentation to discuss the topic of healthy city in an interdisciplinary vision, and to propose and apply a methodology to identify new competencies and how to transfer them, through innovative means, to urban planners, architects and engineers of the future, called to participate in the planning and design process of protecting and ensuring the health and wellbeing of people living in cities.

1. A METHODOLOGICAL APPROACH TO DEFINING NECESSARY COMPETENCIES IN HEALTHY URBAN ENVIRONMENT

The methodological approach was planned to identify the competencies to be acquired by future practitioners - urban planners, architects, and engineers - that design healthy environments from neighborhood to building scale, in order to design specific academic courses within the existing curricula in BiH's Faculties.

Therefore, the methodology aimed to reach these objectives:

1. Understand how the topic of 'healthy cities' is currently dealt with in current university curriculums.
2. Evaluate the student's awareness and perception of the theme.
3. Discuss stakeholders and local experts' opinions and potential of the topic development.

Necessary tools were developed to reach these objectives, and after their application, the results were compared to identify the necessary competencies. First, designing analysis' grids to evaluate the topic in curriculums, and workshops with the Bosnian project team to collect their opinion. Second, design and carry out questionnaires that investigate the Bosnian student's awareness. Third, organize Bosnian stakeholders' meetings and surveys to discuss the theme with the labor market and social needs.

1.1. Evaluation of the faculties' courses: grid questionnaire and workshop

A grid questionnaire on how the theme 'Healthy Urban Environment' (HURBE) is addressed within the existing teaching courses was elaborated. The grid aimed to analyze the whole syllabus studies and the teaching modalities in the degree programmes of the three Bosnian faculties. The grid was prepared by Sapienza University of Rome. It was composed of descriptive tables articulated in two sections. The first section collects general information about the typology of degrees (i.e. duration of the course, total number of university educational credits - CFU; number of students enrolled; methodology of enrollment and selection; main competencies acquired; scale of classes; grading and of final

thesis discussion; articulation of CFU between teaching, individual study, laboratory activities, traineeships, etc.). The second section provided specific information about each course in terms of CFU; scientific disciplinary sector; learning outcome; typology of course (i.e. compulsory or elective); typology of attendance (i.e. mandatory or not mandatory); teaching methodology and tools used (i.e. slides, video, oral lecture, reviewing design, etc.); evaluation method (i.e. final written test, mid-term, written test, oral evaluation, project evaluation); main literature and position of the course in the curricula.

Given that architecture and civil engineering share the same broader area (i.e. organizing building, space, and environment), all three faculties already offer courses that include some aspects of environmental sciences and/or courses on technological means to preserve our environment and create healthy urban settings. At the University of Sarajevo (UNSA),[2] Faculty of Architecture, there are 35 courses that contain topics that could be - in minor or major proportion – discussing issues related to the HURBE, distributed as follows: 7 out of 68 courses in the first cycle (Bachelor), and 28 out of 97 courses in the second cycle (Master). Within the Bachelor cycle, the number of CFU of the topic HURBE related courses is 20 CFU out of 180 CFU. Strangely, the number of HURBE related courses in the Master was estimated to be 145 CFU and the total university educational credits needed to obtain the degree are 120 CFU. This is due to the variety of elective courses at the Master level, many of them were considered to discuss issues related to the healthy urban environment in a minor or major proportion. In UNSA, HURBE related topics include bioclimatic architecture and urbanism, resilient architectural design, human-oriented city, green design, renewable energy, and low-energy housing.

At the University of Zenica (UNZE),[3] Faculty of Polytechnic, Civil Engineering, there are 7 courses (4 compulsory and 3 electives) which contain topics that might be -in minor or major proportion- related to HURBE. They are in the first cycle (Bachelor) courses. Within the Bachelor cycle, the number of CFU of HURBE related courses is 16 CFU out of 240 CFU. HURBE related topics include solving civil engineering problems as the design and dimension of structures, plan and supervise building operation, air pollution, management of water supply and drain of water waste, natural and energy efficiency and energy optimization.

Unlike the previous two universities, which have one Bachelor programme and one Master programme; the University of Mostar (UNMO),[4] Faculty of Civil Engineering has one Bachelor programme and three Master programmes – general, structural and hydro-technical. Only the general master programme includes 6 out of 36 courses that contain topics that could be -in minor or major proportion- related to HURBE. This represents 29 CFU out of 120 CFU. HURBE related topics include water and environmental protection, energy-conscious retrofit of historical objects and urban ecology. soil and water pollution control, waste management, energy efficiency in construction and alternative energy sources, traditional and new building materials.

The grid showed the potential proportion of courses - through the number and CFU - that might include and discuss aspects related to the healthy urban environment. The theme is quite broad, and many arguments can be considered related to healthy urban environment. This is probably the reason that UNSA's Master programme was considered to have a high number of courses related to

[2] UNSA's education process is conducted in three cycles (3+2+3): The first three-year cycle (180 CFU) leads to the title of Bachelor of Architecture. The second two-year cycle of studies (120 CFU) leads to the title Master of Architecture. The third three-year cycle of studies (180 CFU) leads to the title PhD in the Field of Architecture and Urban Planning.

[3] UNZE's education process is conducted in two cycles: The first cycle is 4-year Bachelor of Civil Engineering (240 ECTS). The second cycle is 1-year Master of Science in Civil Engineering (60 ECTS).

[4] UNMO's education process is conducted in three cycles (3+2+3): The first three-year cycle of studies is a Bachelor programme of 180 CFU. The second two-year cycle of studies is a Master programme of (120 CFU). They also have a PhD programme of 3 years (180 CFU)

the theme. Further analysis of each course content can help verify the actual proportion of the theme within these university courses.
The grid provided a general indication of the general themes that each faculty chooses to integrate into their educational path. The analyzed faculties share common aims of creating sustainable infrastructures and structures for healthy urban environments. The approach and topics of HURBE differ in each one depending on the faculty's educational mission and their fields of research. Even though the names of some courses can be similar (e.g. energy efficiency) in the three faculties, the teaching approach and content may significantly differ due to the various subjects and methods of different disciplines.
The results of the previous analysis' were presented to the project participants in a workshop,[5] and the main consideration was that the topic of 'health' and its relation and impact on the urban environment is vast and there is a lack of focus on the theme. It might be discussed within other courses, but it is not well identified or defined as a central topic. During the workshop participants discussed the topic and its content, having in mind the aim of setting up new courses in the existent degree programmes. They tried to identify the common competencies needed for future urban planners, architects, and engineers related to the subject - area, applying the matrix of Tuning with Dublin descriptors.[6] The first results were the identification of two typologies of competencies, 'basic' and 'advanced', that should be transferred in different phases of the degree programmes.

1.2. The students' awareness of HURBE: the questionnaire

The questionnaire on "Healthy Urban Environment: the Bosnian students' awareness" was prepared through a workshop of 18 project members, three of each faculty.[7] It aimed to investigate how the Bosnian students attending the universities perceive the topic of HURBE and evaluate the experience they made during the courses they attended. During the workshop, the attendees were divided into three groups and each group prepared a set of questions. A matrix was organized to compare all the questions and extract the ones everyone seemed to agree on - repeated and/or most significant questions - and elaborate the first draft of the survey. The survey's structure and content were developed and discussed jointly by email to elaborate the final version, using simple and 'familiar' words to facilitate the student's comprehension of the questions.
The questionnaire was articulated in 25 questions with different typologies of answers: closed, multiple responses, or on rating scale. It was divided into two sections. The first part provided general information about the participants' sample (6 questions). The second section investigated the general knowledge and opinions about of HURBE (19 questions).
Initially, the survey was prepared through Google Form to allow further communication via email with the students and facilitate the data elaboration and analysis. However, the three faculties had to translate and print the questionnaire to share it with their students in class. UNZE and UNMO filled a google form after, while UNSA filled an excel file. The sample interviewed consisted of 216 students distributed as follows: UNSA, UNMO, and UNZE filled 97, 53 and 66 surveys respectively. Most of the students that filled the questionnaires attended the third and the fourth years of their studies (75% of the sample) and only 8% of students had international study experience abroad. 63% of the sample were females, which is in line

[5] On the 'credit transfer meeting' hold in 13-17 May 2019, Sarajevo (Bosnia and Herzegovina) at University of Sarajevo.
[6] Tuning Educational Structures in Europe is a Guide to Formulating Degree Programme Profiles, but the project participants adapted it and applied it to the scope of the workshop, setting up courses.
[7] On the 'kick off meeting' hold in 11-13 February 2019, Rome (Italy) at Sapienza University of Rome
[8] According with EUROSTAT in 2017 women accounted for 54 % of all tertiary students in the EU-28.

with the general European trend in the tertiary education level.[8] 40% of students do not live in the city where they attend university, which highlights the importance of integrating new modalities of teaching as online courses.
The results of the survey on general knowledge and opinions about HURBE showed the following: 92% of the students did not hear about 'Zagreb declaration' and only 44% heard about the sustainable development goals, mostly through the internet. They answered that they were the ones responsible for their health (38%), after medical professionals (25%), family (20%), and the urban environment (11%). 48% believe that the environment's effect on their health is negative. 77% of the sample is aware that their future professions are linked to health urban environmental issues, and 77% believe that the building design is important for health. The elements identified to have an impact on health are natural elements: ventilation, light, and greenery, followed by the building materials respectively. 87% think that CO2 is a pollutant. Energy production followed by transport were voted the sectors that most contribute to pollution. 23% answered that the healthy urban environment was found to belong to planning and design, engineering and architecture; 9% voted that it belongs to healthcare services, 4% for economy and politics, and 63% voted that it belongs to all these factors together.
When having to choose up to two types of experts that could contribute to a healthy urban environment, 127 answers identified architects and engineers, 48 chose medical experts, 28 chose social workers and 108 chose all of them. 90% voted 'yes' that the topic is important for their future profession. All participants voted that technical architecture and urban planning are necessary for the architects and civil engineers to achieve a healthy urban environment is, 126 voted for social anthropological skills, and 35 chose medical skills.
When they had to choose their three preferred methods of learning about the topic, 174 votes were given to practice followed by 164 votes for laboratory activities. 73% believe that their future work is linked with ethical principles, 17% don't know and 10% do not think so. Most of the students feel they are not well informed on the impact of the building process on human health; 36 % of them are not sure and 27 % answered not at all and not enough. Also, 72% of students indicated that they would like to attend a course at university on this topic.

The results of the questionnaires highlighted that the students lack the awareness and knowledge of the theme. Almost all of them never heard about 'Zagreb declaration', even if they are aware that the environment could have a negative impact on their health. The positive aspect was the demonstrated interest by most of the students and their awareness of the importance of learning new HURBE skills; they are interested to learn about the topic and participate in the course. They also underlined that they need practice and laboratory activities to acquire all the skills for their professional future.
All the analysis's results were presented and discussed through open debates[9] among the academic staff member of HURBE project in order to the content of future courses.

1.3. The stakeholders' opinions: labour market and the social needs

The stakeholders' meetings aimed to provide indications and guidelines related to the labour market needs in the specific context of BiH; the public sector's tendencies, approaches, and strategies; and the community and social groups' needs. Moreover, it aimed to discuss the structure and topics, to be developed, in HURBE courses, increasing networking and creating agreements with stakeholders.
The strategy, structure, and content of the meetings were discussed during a workshop[10]

[9] On the 'Project meeting' hold in 5-7 September 2019, Zagreb (Croatia), at University of Zagreb.
[10] See note 9

among the academic members from the six project faculties. The stakeholders were identified: architecture/construction studios, companies, etc.; national public institutions (Ministry of Environment, Ministry of Housing/ Planning/Infrastructure, Ministry of Health, etc.); local public bodies (city administration representatives, etc.); international organizations (World Health Organization, EU agencies, etc.); labor market entities and others.

The project members decided to design a questionnaire for the stakeholders, to be filled at the beginning of each meeting, with ten multiple-choice questions. The first seven questions were general and common for everyone. Then, there were three questions that were specific for the representatives of the private enterprise, the representatives of the public sector, and the civil society representatives. Each Bosnian university was asked to include at least 10 stakeholders in the meeting. They prepared their lists of stakeholders to invite them via email, phone calls, and personal contact. It was decided to organize three meetings in three days, each day in a different Bosnian university - Sarajevo, Zenica, and Mostar – facilitating the participation and logistics for the stakeholders of each university's city.[11] In each meeting, a local academic representative coordinated the meeting's activities in their home institution. The total number of participants in the three meetings is 64 persons, including academics staff members; 25 of these were the actual external stakeholders that are not part of the project institutions.[12]

Each event started with the general presentation of the project objectives, followed by the discussion of the structure and topics for HURBE course, and then the questionnaires. After that, there were open discussions that focused on the results of the questionnaires and the potential of collaborations between the stakeholders and the Bosnian universities. The meetings also concentrated on the local experts' feedback regarding the importance of integrating HURBE topic in the Architecture and Civil Engineering curricula, the future contribution it could provide for the local labor markets, and the potential role of the laboratories services that Bosnian universities are installing with equipment dedicated to the theme of healthy urban environment.

Some of the questionnaires and discussions results were common in the three meetings and others were relevant to the specific contexts of reference. All stakeholders agreed on the importance of raising awareness of the healthy urban environment at the university level. They remarked the significance of the gap between the practical skills of recently graduated students and the needs of labour market. The structure of the proposed HURBE courses has to be pragmatic and has to provide content that would enable the graduates to link their acquired knowledge with other relevant influential sectors in the job market. With the inclusion of ethical issues as well as the practical experiences (visit to construction site, use laboratories' equipment, etc.), they believe that HURBE course can cover the various topics of healthy cities. Most of the stakeholders indicated the importance of the laboratories that can provide services for external entities and support the courses. Some have demonstrated interest in using the laboratories' services based on defined agreements with regulations and fees. Others offered their support to the academic staff and the students; they would provide objective observations and assist the teaching processes through the integration of their professional knowledge.

[11] The stakeholders' meetings took place as follow: on the 19 June 2019 at University of Sarajevo, on 20 June 2019 at University of Zenica, and on 21 June 2019 at University of Mostar.

[12] At University of Sarajevo, where 18 persons attended the meeting: 2 from private companies, 2 from public institutions and public utility companies and 11 from the University of Sarajevo. At University of Zenica, the meeting was attended by 21 persons: 2 from private companies, 7 from public institutions and public utility companies, 5 from other project partners, and 7 from the University of Zenica. At University of Mostar, the meeting was attended by 23 persons from following areas: 2 from private companies, 7 from public institutions and public utility companies, 3 form NGOs and 13 from education.

In each meeting, the stakeholder's contribution was also influenced by the given urban context where the meeting took place and the university's profile. In Sarajevo, the external participants recommended that HURBE courses focus on common problems of the metropolitan regions. They have to discuss the infrastructure and urban planning, traffic problems and the importance of bioclimatic architecture and public greenery. In Mostar, the stakeholders concentrated on climate change, urban pollution, water, and waste management issues which are evident there. In Zenica, the focus was on the importance of enhancing the city's nature, the impact of the industry and the air pollution it causes. These results provided necessary external feedback in relation to the course's proposed content. Some of them confirm the students' questionnaire results, others provide additional info. They confirmed the importance of the practical experience and the role of the laboratories to link the university with the job market.

2. MERGING THE RESULTS AND DISCUSSION

The methodology discussed shows how the used tools, including all the actors in the process, is necessary for defining new learning content and teaching methodologies to build up new courses in existing degree courses. It demonstrates the importance of integrating training and practical experiences for the development of well-prepared professional figures, increasing their employability.

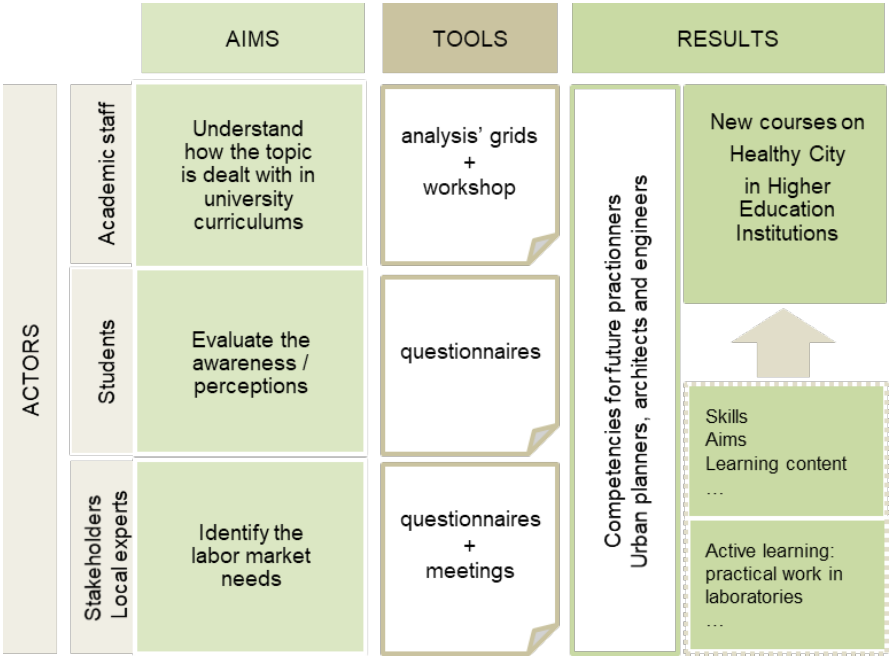

Figure 1. Methodology applied for developing course in Higher Education Institutions on Healthy Urban Environment: Actors, Aims, Tools, Results. Source: (Authors 2020)

Each tool provided an understanding of how the topic of Healthy Urban Environment is a transversal topic to all the disciplines taught in the existing degree courses and consequently diluted in different subjects, with different inflections.

The three tools' results provide a set of common indications. They all showed that there is an absence of a deep understanding of the topic including the concept of health and its effects on the built environment.

Although the students and stakeholders are aware of the importance of the theme on a professional, social and personal scale, the curriculum analysis has shown that the curriculums lack the in-depth recognition of the theme's content and knowledge. The positive aspect, however, is that students are aware of their lack of knowledge of the topic. They are interested in acquiring this knowledge and complementing it with practical training, as they believe it will play a strategic role in their future practices.

The stakeholders' meetings' outcomes stressed that each Bosnian faculty should be able to maintain the balance between the interdisciplinarity of the theme and their specific mission as architecture or civil engineering faculties. They also stated that it is important to link the university teaching curricula, and the new courses on HURBE with the needs of the labor market in the place/context where the universities are located. In fact, the cities of the Bosnian universities involved, even if the country is one of the smallest in Europe, have different urban environments and different problems.

All the stakeholders underlined the strategic role of the laboratories, as a space for active and practical learning, providing the possibility of applying academic research and other activities on the territory.

This role corresponds perfectly to the rising relevance of the universities 'Third Mission'[13] of generating knowledge outside academic environments to the benefit of the social, cultural and economic development, in dealing with the territory and the society, performing activities and projects to strengthen dialogue and interaction among university, industry, and society.

Based on the evaluation of the faculties' courses and the stakeholders' feedback, the academic members decided to divide HURBE course into two interdisciplinary modules with different aims to gain professionals soft and hard skills. The basic module, focusing on theoretical interdisciplinary knowledge and the advanced module, concentrating on practical and design activities. The basic module, HURBE I, will be common among Faculties, allowing the possibility to create an interdisciplinary space for intra-country students and academic staff mobility with the presence of practitioners as teachers too. The main learning outcome is understanding the impact of planning and designing on the urban healthy environment at the different scale; in a wide terms, the students develop the sensibility to put in the core of the actions the 'health of people' and the consciousness of the importance to including and empowering the people in the making process for a Healthy City.

The advanced module, HURBE II, will be specific for each faculty, concentrating on its urban environment context, and adopting the laboratories as a resource for practical teaching and design activities. The learning outcomes are specific in applying methods, instruments and tools to planning and design, starting from the population's health data, and in evaluating the impact on the health of people.

The methodology discussed and its results reconfirm the added value in maintaining a strict link between Education, Research and Third Mission activities. This connection enriches the learning process, and it is necessary for the success of the university courses.

[13] The University has three missions: the first mission is Teaching, the second is Education.

CONCLUSION

There is rapid evolution of the body of knowledge, teaching and teaching methodologies. Information and communication technologies have had a significant role in changing the whole system of processes to develop professional figures that are up to date and able to stimulate urban transformation. With the development of social needs and life demands, even the concept of "health" is modifying and becoming closely relevant to the profession of architects and engineers. The Faculties of Architecture and Civil Engineering are struggling to cope with these rapid changes and prepare professional figures that possess the necessary knowledge. In addition, universities need to follow the paradigm shift from the "Teacher-Centered model" to the "Learner-Centered model" (Bishop, Caston and King 2014).

This paper underlined the importance of various elements in developing a learning process. Future architects and engineers have to be able to deal with the evolution of 'hard changes' (i.e. new materials, methods of producing them, etc.) and 'soft change' (i.e. equipment and software as Building Information Modelling, etc.). It is important to update existing architecture and engineering curricula with new content, integrate practical experience like laboratories and develop links with the labor market and social needs.

By applying the indications and results of the proposed methodology, the new professional figures should develop a set of hard skills (knowledge of the topic, using laboratory equipment, etc.) and soft skills (communicating with the labor market representatives, decision making, etc.), filling a gap between education and relevant professional requirements. These future practitioners should be able to stimulate urban transformation for healthier built environments and capable of adapting to the continuously updating environmental and social changes.

Designing healthy urban environments is a challenge that requires the ability of critical thinking to position the concept of health of the inhabitants in the center, in accordance with a given context. It is an action of dreaming about the future of the city. It is a process of co-creating and co-dreaming that involves all actors (academic staff, researchers, stakeholders, inhabitants, etc.) and, in a broader meaning, the whole sectors of civil and political society. The article aspired to participate in that action, its actors and results are representative of the Bosnian context - within the framework of the European Commission's co-funded Erasmus+ project - however, the methodological approach provides guidance and can be replicable for other curriculum development projects for a healthy urban environment and/or other topics in Higher Education.

PAPER #7.21

NATURAL VENTILATION IN THE TRADITIONAL COUNTRYSIDE CONSTRUCTIONS IN VALENCIA. CFD & PPD ANALYSIS.

F. Mendiguchia[a], A. Quintana[a], I. Guillén-Guillamón[a]
[a] Physics Technologies Center. Polytechnic University of Valencia, Valencia, Spain

ABSTRACT

Local Valencian architecture has evolved over the centuries adapting to the region's climate conditions. Orientation is one of its fundamental aspects to guarantee the perfect amount of sunlight and natural ventilation. Thanks to the proximity to the Mediterranean Sea and the relative position to the Garbi mountain, the stable wind conditions ensure a good ventilation in the countryside, commonly called "Horta".
The main objectives of the study are divided into two parts. The first phase is focused on the typological and historical study of the popular buildings on Valencia's "Horta", located at the "L'horta Nord" region. A second part will be focused on virtual CFD models (Computational Fluid Dynamics). Natural ventilation inside the buildings is analysed with different local winds configurations. Also, the benefits of this ventilation are studied with reference to interior comfort, using PPD analysis (Predicted Percentage of Dissatisfied). This study shows how the case study adapts itself to the microclimatic region conditions.

KEYWORDS

Natural ventilation; CFD models; popular architecture; interior comfort; PPD models.

INTRODUCTION

Sustainable architecture has been gaining relevance in recent decades. In order to move closer to the sustainable goal, it is necessary to work on a local approach that allows the adaptability of different architectural solutions, like the use of local materials or morphological conditions such as the type of roof, orientation, shape of the windows, symmetry conditions (Neila González, 2004). Therefore, it is interesting to study popular architecture to find the core elements of their design strategies. In this case study, we will focus on analysing the natural ventilation in the popular buildings of the Valencia countryside using CFD & PPD analysis. (Mora-Pérez et al., 2016)
Valencia is located on one of the few coastlines of the Mediterranean with an eastern slope. Thence, it is leeward the normal atmospheric airflow in this hemisphere. The proximity to the different mountain ranges, such as the Betica and Iberica, causes a strong pressure differential. Also, many of these mountains are perpendicular to the coast, thence the air from north to south is blocked. These peculiar geographical conditions protect and intensify by the thermal differential between land and sea that cause the natural breeze. Daily stable east-west or west-east wind routines are established, depending on the Atlantic influence. (A. J. Pérez Cuevas, 1994)
The stable winds and mild temperatures, typical of maritime region, provide ideal conditions for natural ventilation.(Alonso Monterde et al., 2016). To demonstrate this fact, we will use the Climate Consultant application, which is capable of interpreting data from climate files. The climate files of a region contain essential climate information, such as temperature, humidity, irradiation, airspeed, and direction. With this

information, the application represents us within a welfare bioclimatic chart, based on the Givoni's bioclimatic chart (Olgyay, 1998), all the hours of the year with their respective hygrothermal conditions. Also, it allows us to quantify the number of hours that are in each zone of the bioclimatic chart of well-being. Therefore, from a designer point of view, it allows us to evaluate which should be the project measures to adopt for a specific climate.

In figure 1, we can see the representation of all hours of the year (green dots) with their respective hygrothermal conditions for the climate of Valencia. The Mediterranean climate is quite mild, so we can find a comfortable situation for 1173 hours a year, which represents almost 14% of the year. Also, an adequate sun protection system for the windows could increase the comfort to 1366 hours, almost 16% of the year. However, these protection systems must be adaptable to achieve up to 2924 hours (33,4% of the year), because solar gains are needed in order to increase the internal temperature. Finally, natural ventilation can generate a total of 1434 hours of comfort (16,4% of the year). Without the contribution of natural ventilation, we would have to solve the comfort conditions using air conditioning. That would mean using this system 24,6% of the year. Thanks to natural ventilation,

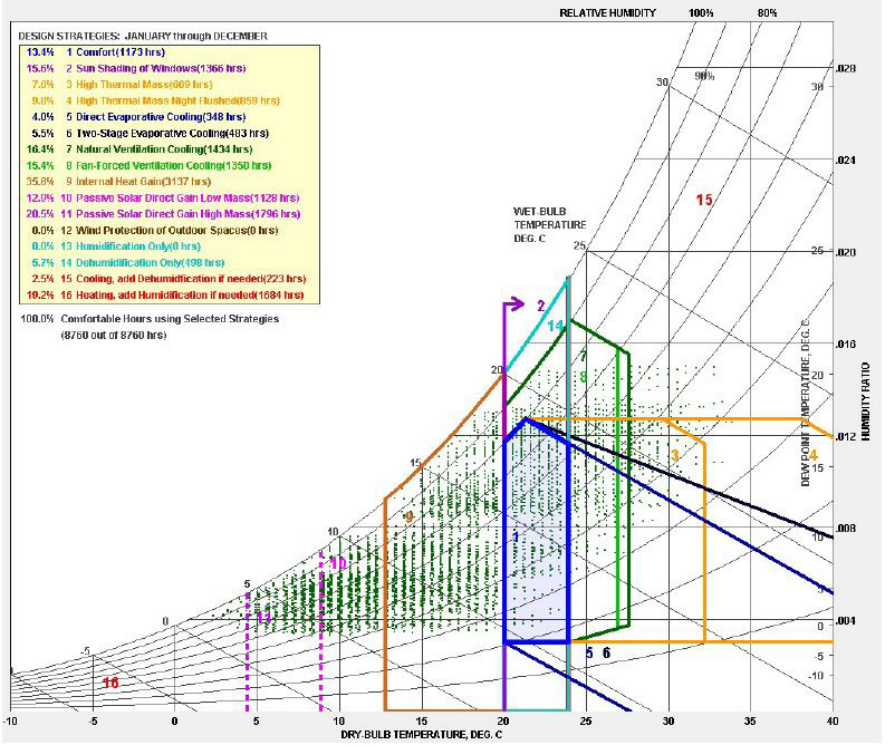

Figure 1. Bioclimatic Chart for Valencia's climate (Climate Consultant Application).

only 8,2% of the year. Therefore, we can save energy by reducing the operating hours of air conditioning. That's the reason why natural ventilation is an adequate strategy in this region.

1. CASE STUDY

There are two main kinds of traditional rural constructions in Valencia: *Alqueria* and *Barraca* (Rey Aynat, 2002). *Barraca* is a basic type of construction based on a gable roof with a steep slope that almost touches the ground. It's humble construction, characteristic of the southern area of Valencia, known for its rice fields surrounding a coastal wetland called Albufera. On the other hand, the *Alquería* is a more elaborate construction, consisting of two or three stories. Its name derives from the Arabic "al-qarïa" and refers to a group of small isolated villages. Currently, the word refers to those isolated houses built surrounding farmland.
Alqueria is a rural house normally composed of two levels. On the ground floor, we can find the bedrooms and dining room. In case they have a kitchen or bathrooms of any kind, they are located outside the construction. The purpose of the first floor was drying vegetable products, like xufa, a local kind of ground nut used for the production of orxata, straw and even tobacco. *Alqueria* has a gable roof made of tiles and its brick walls have a whitewashed finish. Structurally the constructions have two naves divided by a central portico made of solid brick. The facades are load-bearing walls. These constructions are usually symmetrical in two directions. For this reason, the facades have a symmetrical composition. Also, both the east and west facades have their windows aligned. Because of their agriculture function, the houses are oriented to the east to capture the sea breezes. Therefore, these houses are a very interesting case study to analyse natural ventilation in popular architecture.

Figure 2. Case study

The selected *Alquería* is located in the municipal district of Alboraya, more specifically in the *Partida de Saboia* in a sector of the *L'horta Nord* area between the *Carraixet* ravine and the CV-311. It is isolated, surrounded by fields destined to the orchard, with the nearest houses appearing at 115 meters, and it is considered a free environment exposed to the wind. On an architectural level, this *Alquería* is of a compact type with two naves parallel to the main façade. The house as such is arranged on the lower floor, while the upper floor houses the drying and storage area. The house has on its two sides two "porxadas" that served as corrals access to one of them is through a particularly wide door, which is necessary for a car to enter. The main façade has partial symmetry, due to the construction phases of *Alquería*.

2. METHODOLOGY

To analyse ventilation, we must be able to quantify it on the one hand and assess it on the other. To quantify it, we will carry out CFD analysis, Computer Flow Dynamics. (Hajdukiewicz et al., 2013) We can define CFD like a methodology of calculation based on different parts: discretization of a continuous flow defining its calculations domains; discretization of the equations

of the movement, from integral equations to algebraic equations; and solve these algebraic equations through reiterative calculations method. These specific CFD simulations provide valuable information about the environmental conditions of the construction, as much from outdoors as from indoors. These simulations will depend on many boundary conditions, which we must predefine before each analysis. Therefore, CFD analyses consist of simulations of fluid dynamics through or between objects, like in a virtual wind tunnel. These techniques allow us to evaluate the effect of the air on the constructions and can take into a count different conditions that the same environment. Also, we will be able to obtain Air age results. The Air age is a parameter expressed in seconds and counts the time that the air needs to renew one calculation cell. This parameter allows us to evaluate the natural ventilation and air renewal capacity of the system. On the other hand, to evaluate the natural ventilation, we will carry out PPD analysis, Predicted Percentage Dissatisfied. This index is a percentage value of the number of people who would feel uncomfortable in certain hygrothermal conditions. This percentage value is a mathematical relationship based on statistical values. We can assume as an indicative value that the PPD shouldn't exceed 20% of dissatisfied people in an indoor space. (ISO, 2005)

We will divide the CFD analysis into three parts. First, an exterior analysis, where we will be able to study the behaviour of the air in the construction environment, observe its pressures, speeds, and directions. Secondly, an internal analysis whose data we will use for the third step, the PPD analysis.(Mora-Pérez et al., 2015)

To perform CFD and PPD analysis, we must define the environmental conditions. In this study, the software we will use, DesingBuilder, consists of reading weather files, so we will only focus on air direction and speed conditions for CFD configuration. The reference station is at the Manises Airport, the level above sea level is considered 62 meters. With this climate data, we can represent the wind chart that you can see in Figure 4. We can identify six representing cases, expose into the Table 1.

	Air Speed m/s	Air Temperature ºC	Air Humidity %
East 80 degrees	12	27	80
	6	24	80
	3	20	80
West 270 degrees	12	18	45
	6	15	60
	3	15	60

Table 1. Wind conditions study

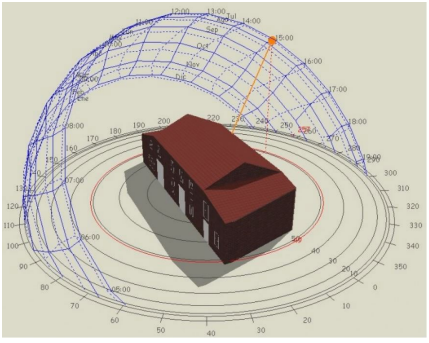

Figure 3. Climate configurations. (DesignBuilder software)

The first step is to perform external analyses. We will be able to observe the performance of the construction in terms of the surrounding airflow in the different wind configurations. From these external analyses, we extract information about the wind, such as direction, flow or temperature. With this data, we can set up CFD surfaces for internal analysis. The CFD surfaces are elements of the DesignBuilder software that allow us to configure extracting and impulsing air according to the air balance configuration. Also, we can modify these surfaces to introduce the input and output

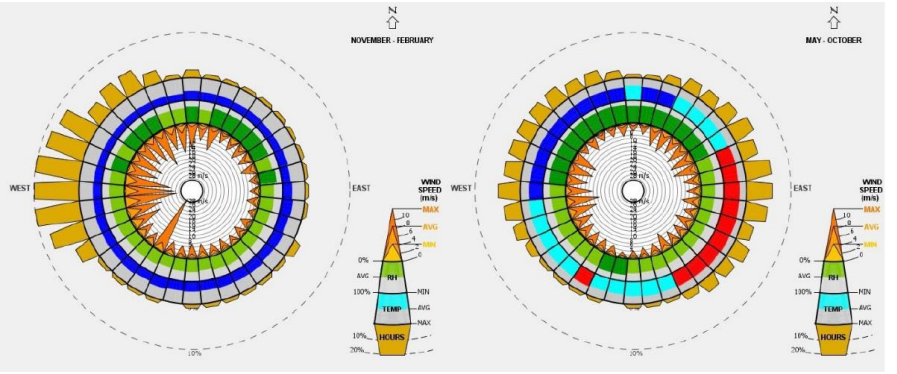

Figure 4. Wind chart. November-February. May-October. (Climate Consultant Application)

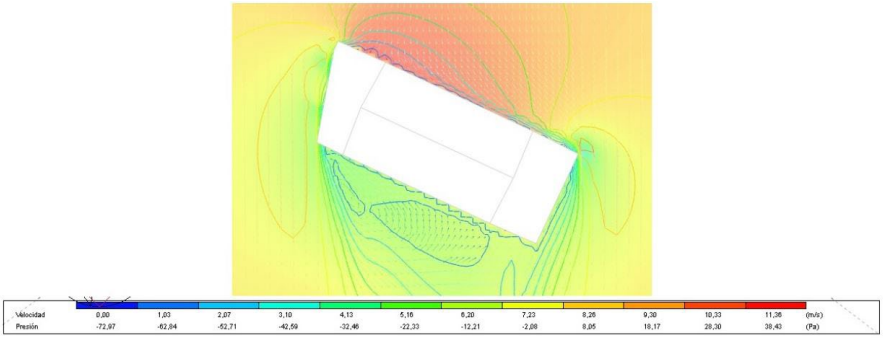

Figure 5. External CFD analysis. (DesignBuilder software)

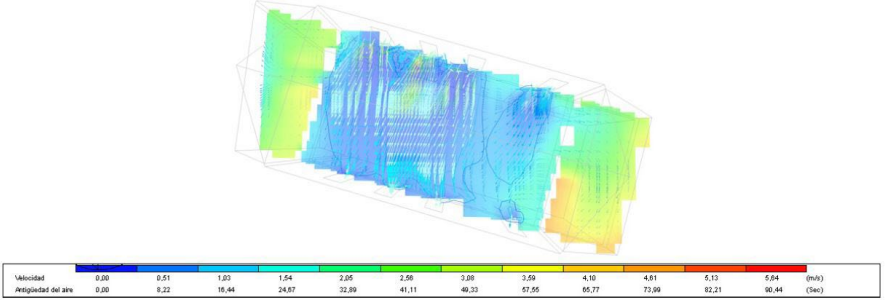

Figure 6. Internal CFD analysis. (DesignBuilder software)

conditions that we obtain in the external analyses. We can see one example in Figure 5. In the second step, we will perform the internal analysis that will report data like airspeed, direction, and age. These values allow us to quantify the effectiveness of the ventilation. For example, in Figure 6, we can see the vectors of airspeed and the age of air for the east wind whit 3 m/s airspeed. Regarding the airspeed, we observe speed peaks at the entrance or exit of 2 m/s airspeed, this is due to the Venturi effect caused by the façade openings. We must distinguish two different zones in the interior space. The first zone there is just inside of the airflow that througing the building. The second zone there is outside this airflow. Inside the airflow, we observe velocities of approximately 1.54 m/s and an air age of 8.22 s. Outside the main flow zones, the air moves at a speed of approximately 0.5 to 1 m/s, with the age of the air being between 10 and 30 seconds.

With the results of the internal simulation, we can perform the PPD analysis. In this third step, we will need to define some parameters like metabolic conditions (0.7) or clothing indices (0.5). Continuing with the example, Figure 7, we can see that in the airflow areas the percentage of dissatisfied people is around 23.7 %. However, in the zones outside this airflow, we find a percentage of dissatisfied around 5% or 11.06 %.

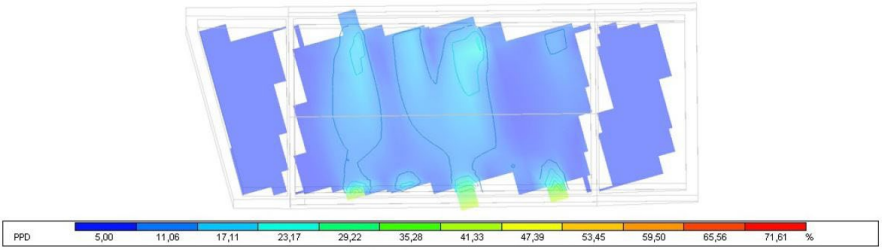

Figure 7. PPD analysis. (DesignBuilder software)

			Airflow area			No affect by airflow area		
			Speed m/s	Age of Air s	PPD %	Speed m/s	Age of Air s	PPD %
East 80 degrees	12	F1	10	0	12,3	6	0	19,5
	m/s	F2	12	0	10,04	6	0	18,7
	3	F1	4	4,24	24,6	1,37	12,71	11,08
	m/s	F2	5	4,24	23,17	2,73	8,47	8,1
	1,6	F1	1,54	8,22	41	0,51	24,67	12
	m/s	F2	2,5	8,22	48	0,51	16,44	20
West 270 degrees	12	F1	7,75	0	90	5,17	11,97	43

	3	F1	3,87	7,46	50	2,32	18,64	21
	m/s	F2	4,55	3,73	60	2,32	14,91	29
	1,6	F1	1,25	15,33	33	0,42	45,99	6
	m/s	F2	2,51	7,07	47	0,84	30,06	13

Table 2. Table of internal CFD results

3. DISCUSSION

Based on the results we can analyse two phenomena. Firstly, if we observe the airspeed, we note important variations between the first and second floor, around 1 m/s and 2 m/s airspeed. This fact has a direct effect on the PPD percentage. In all cases, the PPD percentage of the first plant is higher than the second plant. We can explain this effect with several factors. On the one hand, the dragging effect of the land causes a speed differential between the facades of the first floor and the second floor. On the other hand, according to the characteristics of the case study, the ground floor has unaligned windows that disturb the airflow. However, on the second floor, there are windows aligned due to the symmetry of the east-west facades. For that reason, the airflow isn't blocked by static air masses. Therefore, natural ventilation is more effective on the second floor thanks to its higher height above the ground, which allows it to capture winds at greater speed. Also, its distribution of symmetrical windows on the perpendicular facades the wind direction. Note that the purpose of this floor is drying agricultural products. Therefore, it isn't surprising that we find better natural ventilation results, since it was precisely designed for that objective.

Secondly, there are significant differences between the PPD results of the eastbound wind and the westbound wind. This is mainly due to the seasonal regime to which these winds belong. The wind from the West is more frequent during the autumn and winter season. Therefore, associated temperatures are too cold to be comfortable. Furthermore, if the west wind occurs in summer, we can associate it with the characteristics of a *terral* wind. Terral is a dry and warm wind originated by the pressure difference between mountain ranges and flatlands near the seacoast. *Terral* wind does not have the necessary characteristics to guarantee thermal comfort through natural ventilation. However, the capture of this dry west wind is essential for the drying process of agricultural products. As said in previous paragraphs, the main objective of this kind of building is to be used for agricultural purposes. And in this case, the building efficiently uses natural ventilation for this function.

Unlike the wind from the West, the East wind, is better suited for natural ventilation. This is a thermal wind; therefore, its intensity increases proportionally to the inland temperature. This phenomenon is ideal, due to the fact that the more the temperature increases the more airflow its needed to reach comfort conditions. As we can see, in *Olgyay's* (Olgyay, 1998) hygrothermal comfort chart. As a result, the PPD analyses of the east wind combinations practically guarantee comfort conditions. The *ASHRAE 55* recommends PPD values of around 10 percent. However, the results obtained in many PPD analyses far exceed this value. This is because, usually, comfort statistical data is collected from northern regions. *Victor Olgyay* states (Olgyay, 1998) that humans are capable of varying our comfort temperature to adapt to the climate in which we are.

Indeed, if we adjust the thermal comfort values in the Climate Consultant application, we can obtain results that are closer to the reality of the local population. We can increase the thermal comfort up to 2 degrees, reaching 25.9 degrees. The relative humidity could increase up to 5 points, reaching 85%. Finally, the airspeed could change, from 1.5 m/s to 2.5 m/s, with high temperatures and high humidity air conditions. With these comfort parameters, the comfort hours obtained in the hygrothermal chart increase by 4%, and 3.7 % the ones related to natural ventilation. Also, the need for cooling decreases to 0.6%, which represents only 56 hours a year. This last datum does not consider the needs of air dehumidification. Therefore, the comfort conditions would likely reach the values required by ASHRAE if there were statistical data collected from the region of study.

CONCLUSIONS

- We can confirm that the orientation of the traditional constructions in Valencia is perfectly oriented to capture the wind of the region in the most efficient way.

- The type of openings and their arrangement on the façade, that is, high and narrow windows, are very useful for compressing and therefore accelerating the air as it goes through them.

- The symmetrical façade arrangement facilitates airflow through the construction, minimizing the number of turbulences and air pockets at different speeds.

- With the climatic data presented and verified with the CFD & PPD simulations, we can state that the region of Valencia has an ideal wind regime for natural ventilation as a bioclimatic design strategy.

- The CFD & PPD analyses are a relatively simple and useful tool to be used also in new projects. It would be interesting to implement this work dynamic in the initial phases of a project.

- Natural ventilation is one of the most useful bioclimatic design tools in almost all the Mediterranean arc, almost in the territories near the coast. It would be interesting to transfer this experience of study on natural ventilation to more exhaustive analysis conditions based on Indoor Air Quality, IAQ. With this methodology, we could analyse if quality of air and its pollutions is adequate for natural ventilation.

- It is necessary to carry out a deep analysis of the tools to obtain PPD results, specifically their databases, to adjust the analysis parameters to the real comfort conditions of the population in the latitudes and regions of study.

PAPER #7.22

ECOMIMETICS: THE MAXIMUM POWER PRINCIPLE FOR RETHINKING URBAN SUSTAINABILITY

Mercedes Garcia-Holguera[a]
[a]University of Manitoba, Winnipeg, MB, Canada

ABSTRACT

Despite their numerous achievements, mainstream approaches to sustainable design have failed to address global environmental challenges from a complex systems perspective. For some critics this is rooted on a reductionist understanding of design solutions that gravitates towards the first law of thermodynamics (energy efficiency); whereas buildings, neighborhoods, and cities should be comprehended as self-organizing complex systems. As Lotka pointed out, the first and second law of thermodynamics alone cannot unravel the energy dynamics of these type of organizations, and a system thinking approach is required. Mimicking ecosystems' self-organizing structures provides an alternative pathway to design cities as complex, resilient structures. Ecosystems exist at many scales, inside the stomach of a ruminant or as an entire rainforest and, through evolution, have adapted to extreme conditions that in many cases involve limitation of resources, daily and/or seasonal increase or decrease of temperatures, overpopulation, or catastrophic events. More interestingly, ecosystems adhere to the maximum power principle as re-defined by H. Odum, which states that systems that maximize their flows of energy tend to persist over time. This principle suggests that, counterintuitively to our beliefs, systems that use more resources can be more effective in the long term. Cities, like ecosystems, are self-organizing complex systems. Their complexity arises from the flows of energy, matter and information through the multiple components that maintain the whole city system in a steady state, away from thermodynamic equilibrium. Here it is proposed that for cities to prevail and be resilient in the context of a changing climate they need to maximize renewable energy flows and minimize entropy generation.

Biomimetic design; ecomimetics; ecosystem biomimetics; systems thinking; maximum power principle.

INTRODUCTION

Unrestrained anthropogenic development causes environmental changes at a global scale. Long-term impacts in human and non-human systems are expected and only mitigation and adaptation measures will help to manage these impacts (Rajendra et al. 2014). Rokstrom et al. (2009) introduced the idea of planetary boundaries and argued that operating within these boundaries could assure a stable global environment, but anthropogenic development is estimated to have already transgressed three of these boundaries: climate change, biodiversity loss and nitrogen cycle disruption.

The consequences of crossing one or more boundaries are unpredictable because the Earth is a complex self-regulating system as described in Lovelock's Gaia theory (Lovelock 1972), and the interdependency between variables implies that changes in one variable or system might provoke the transgression of one or more other boundaries. One variable that controls climate change is atmospheric CO_2 concentration. The increase in CO_2 levels is directly connected to the building industry (due to energy use) and indirectly to architectural

design choices (which affect energy use). In addition, resource scarcity is also a critical topic on a finite planet where buildings and the building industry are accountable for 30% of raw material use and 40% of energy use globally (Huovila et al. 2010). The problem of resource scarcity is more evident when the Earth is characterized as a thermodynamic system, closed to matter and open to solar energy. The first reflections on scarcity in connection to population growth were documented in Malthus' seminal paper (Malthus 1798). Later on, Jevons studied the negative and counterintuitive results of improving technology and increasing energy efficiency in the context of coal mines (Jevons and Flux 1906). According to the so-called 'Jevons' paradox', increased efficiency stimulates more resource use due to relatively lower costs associated with the more advanced technology. Similar conflicting aspects regarding energy efficiency were also observed in physical and non-physical systems, and described as the maximum power principle (Odum and Pinkerton 1955). This principle states that, in a context of abundant resources, all living and non-living systems tend to capture as much energy as possible to produce maximum power output, and only when resources are scarce do systems tend to favor efficiency. These ideas align with the observed evolution in human made systems where augmented access to energy sources, (e.g. development of agriculture, the Industrial Revolution) triggered important technological and scientific advances that increased exponentially the use of resources, but also increased the complexity of human systems. According to the maximum power principle, this unrelenting capture of high quality energy is common to all living systems. This document will discuss how the maximum power principle can help support counterintuitive ideas for complex systems centered environmental design

Architects and urban planners have traditionally reflected on the relationship between buildings, energy and the city (Geddes 1950, Mumford 1963), but these ideas had little repercussion in the built environment until the oil crisis in 1973. During this period of relative 'energy scarcity' efficiency measures took preference over maximum power strategies, and the foundations of sustainable design where established around matter and energy use concerns.

The approach to environmental design represented by sustainable architecture has been very successful in raising awareness of limited resources and climate change challenges. It also has provided global but reductionist tools to assess the environmental performance of buildings (e.g. LEED, BREEAM); however, sustainable design has failed to address the environmental challenge from a complex systems perspective. Whether the study is focused on a building, a neighborhood or a region, these are self-organizing complex systems and the first and second laws of thermodynamics alone cannot unravel their energy dynamics.

Mimicking nature appears to be an inspiring approach to environmental design capable of conceiving buildings as complex systems. Although there are many angles to the definition and characterization of biomimetic design, a central idea is that biological systems have accumulated countless successful design solutions through millions of years of evolution and adaptation (Benyus 1997). In that regard, biomimetics refers to the study, understanding, abstraction, and modeling of biological systems with the purpose of solving technological and design problems (ISO 2015). The term has also been defined as "learning from nature" in contrast to trying to copy nature, meaning that a deep understanding of biological functions and processes is necessary for successful developments. Biomimetic design argues that humans can learn from nature's vast experience and, when intended, environmental goals can guide the design process. Among the possible biological systems that can interest designers are ecological systems. Mimicking ecosystems is

also known as ecomimetic design and refers to biomimetic research that learns from and emulates ecosystem processes and functions in design exercises (Garcia-Holguera et al. 2015b). Cities and buildings, like ecosystems, are complex systems; and their complexity arises from the variety of their components, both biotic and abiotic, and from the flows of energy, matter and information that connect their elements and maintain the system in a steady state, away from thermodynamic equilibrium. Ecosystems exist at many scales, inside the stomach of a ruminant or as an entire rainforest and, through evolution, ecosystems have adapted to extreme conditions that in many cases involve limitation of resources, daily and/or seasonal increase or decrease of temperatures, overpopulation, or catastrophic events, for example. Persistent ecosystems have a complex network of interactions among their components that ensures their resiliency and maintains essential energy flows in the system even in adverse conditions. These characteristics suggest that mimicking ecosystems' complexity and energy dynamics might have great potential both for innovative urban and building design and for optimization of buildings' environmental performance.

1. ECOSYSTEMS INFORMING CITY PLANNING / CITIES MIMICKING ECOSYSTEMS

There are multiple definitions that try to grasp the nuances of the term "ecosystem". One definition commonly accepted is the one given by the Convention on Biological Diversity: "a dynamic complex of plant, animal and microorganism communities, and their non-living environment interacting as a functional unit" (United Nations 1992). Another similar definition is the one by H. Odum (1994) that describes an ecosystem as "an organized system of land, water, mineral cycles, living organisms, and their programmatic behavioural control mechanisms". The study of ecosystems is presented by some researchers as a holistic discipline (Odum 1977, Jørgensen 2002) in which ecological systems are described as hierarchical structures of nested levels that increase in complexity and self-organization through time (Kay 2004). Also it has been established that mature ecosystems with more complex structures (i.e. more elements, more food chains, etc.) are more efficient in their biomass to energy use ratio (Margalef 1963), and the same author stated that a similar correlation could be found in human systems; where urban centers could be compared to mature and more efficient ecosystems whereas rural areas would correspond to less mature ecosystems. Other authors agree in recognizing that both building and ecological systems can be characterized as open thermodynamic complex systems (Allen 2001, Fernandez-Galiano 1991, Kibert, Sendzimir, and Guy 2000), but it is the correlation between energetic flows in cities and living systems that has drawn more attention (Allen 1998, Purvis, Mao, and Robinson 2019, Marchettini, Pulselli, and Tiezzi 2006). Three characteristics of ecosystems are particularly relevant in the context of ecomimetic and environmental design of cities: Ecosystems are complex systems that function as thermodynamic open systems and follow the maximum power principle.

1.1. Cities characterized as complex systems

Cities and ecosystems behave like complex systems in that their outputs do not stem from linear interactions but are rather the result of multiple feedback loops. Feedback loops are pathways that reinforce or suppress the processes that characterize a system (Odum 2004). A system is made of components, their interconnections and a number of particular functions or purposes (Meadows and Wright 2008). Components or elements in a system are easy to identify, interconnections (such as feedback loops) might be harder to find, and are essential when trying to understand or

restructure a system. The purpose of a system can be deduced from its behavior, and a system might be formed by multiple subsystems with different purposes. Changing the elements in a system can keep the system unaltered; however, changing their interactions or the purpose can significantly modify the system. In an urban system, the interactions between the city components and their reinforcing feedback loops generate specific patterns through time. Some of these behaviors respond to purposes that have defined our cities as residential, economic and socio-cultural spaces. It is crucial to modify these purposes and interactions so that anthropocentric urban systems can evolve into biocentric ones. An urban system whose success is measured by its capacity to provide clean air will be very different from one that aims to provide fast vehicular access to its citizens.

Furthermore, systems theory has shown that urban planners and architects can learn from ecosystems' organization and structure. It appears that complex systems tend to share structural features (Anand et al. 2010) and that there are general common principles to many systems that are independent of its components or the local interactions among those components (Von Bertalanffy, 2008). It is also known that systems that seem to be completely dissimilar can generate similar dynamic behaviors (Meadows and Wright, 2008). These ideas are especially relevant when thinking of cities and ecosystems which are two types of systems with apparently few things in common. It makes sense then that mimicking ecosystems' feedback structures might guide designers towards repurposed urban systems.

1.2. Cities characterized as open thermodynamic systems

The thermodynamic field is another link between urban systems and ecological systems as both system types have to deal with variation and regulation of their energetic inflows and outflows. However, one interesting difference is that in the built environment the first law has mostly ruled the approach to thermodynamics. Kay (2004) points out that while the first law of thermodynamics is a description of energy flows in terms of their quantities, the second law has to do with their energy quality. In other words, with the first law we measure efficiency whereas with the second law we describe the effectiveness of the flows. Kay argues that, historically, technology and engineering have concentrated on the quantifiable aspects of energy exchanges, rather than focusing on the quality of those exchanges.

Fernandez-Galiano (1991) compares the "culture of energy", which is represented by a society that seeks increased production and resource consumption, with the "culture of entropy" that focuses on conserving resource, and values energy quality. The second law of thermodynamics and the concept of entropy bring out the notion of irreversibility in all processes and the inevitable decay of systems through time. Cities, however, like ecological systems, perform as dissipative structures that maintain their structure and/or morphology thanks to the constant inflow of high quality energy. This high quality energy that is able to perform work is called exergy. Exergy is always lost during the lifetime of any system, in stark contrast with the conservation of energy guaranteed by the first law of thermodynamics. When all exergy is consumed and there are no inflows of exergy, the system tends to reach thermodynamic equilibrium which in ecological systems is equivalent to death.

The concept of exergy is also very helpful in understanding self-organization processes of ecological systems. When the internal exergy in a system is greater than the exergy needed for the maintenance of the system, then the system uses that excess to create new order; these types of organizational structures are Prigogine's (1968) dissipative structures. Kay et al. (1999) restates the work of Prigogine who pointed out that open systems receiving exergy are moved away from equilibrium and

Kay adds that, despite this, Nature still tends toward equilibrium. Within this framework, Kay (1999) defined what he called the Self-Organized Hierarchical Open systems or SOHO systems and argued that ecosystems have to be understood as SOHO systems in order to develop an ecosystem approach. Analogously we could say that cities also have to be understood as self-organized open systems in order to develop a design approach that mimics ecosystems: ecomimetics.

In addition, there is another interesting concept in terms of energy accounting for ecological systems and buildings. The concept of "emergy" or embedded energy was first coined by Odum (Odum 1994, 2004, Odum 1996) and refers to the amount of energy of just one type that is necessary to make one unit of another type of energy. The idea is based on the notion of energy hierarchy in ecological systems; that is, in ecological processes "at each step much of the energy is used in the transformation, and only a small amount is transformed to a higher quality, one that is more concentrated and in a form capable of special actions when fed back" (Odum, 1994). The ratio of emergy vs. energy is called the "transformity" ratio, and Odum states that emergy analysis can be used to place cities and buildings in their energy hierarchy level. Comparing ecological systems with human systems in terms of emergy/exergy ratio shows that natural systems have a lower ratio than man-made systems; which in other words means that, when referring to solar radiation, ecological systems are more effective in capturing exergy; that is, natural systems have evolved to maximize the useful work that they can perform with incoming energy flows. Emergy has been used to analyze the energy hierarchy of ecological systems and it has been proposed as a means to assess the energy hierarchy of buildings and cities (Odum, 1994). Emergy analysis has also been implemented to maximize renewable resource use in buildings (Srinivasan, et al. 2012), to conduct life cycle assessment (LCA) in buildings (Srinivasan, et al., 2014), to optimize urban design (Lee and Braham 2017), and to evaluate eco-efficiency of building manufacturing (Li, et al., 2011). The use of thermodynamic approaches in ecological systems and urban studies is not new. In the past, researchers have stated similar interpretations of the second law of thermodynamics in the context of resource use of buildings (Fernandez-Galiano 1991, Mumford 1934), and urban systems (Wilson 2010, Kapur† 1982, Balocco et al. 2004, Nielsen and Jørgensen 2015, Purvis, Mao, and Robinson 2017, Fistola 2011, Pelorosso, Gobattoni, and Leone 2017, Wilson 2009). This extensive work supports the idea that thermodynamics is an appropriate means to convey relevant concepts from ecology to architecture and urban design in the context of ecosystem biomimetics.

1.3. Cities and the Maximum Power Principle

Advancing further in the similarities between ecosystems and urban systems, the Maximum Power Principle (MPP) may appear as a disruptive concept when associated to the practice of environmental design. Lotka was the first to discuss the idea of a maximum-energy-flow governing principle in an effort to explain the thermodynamics of living systems in the light of Darwin's natural selection theory (Lotka 1922b, a). This principle expresses that living systems compete for available energy and aim to maximize the capture of useful energy (i.e. exergy); the type of energy that allows these systems to sustain their structures first, and increase their complexity subsequently (i.e. evolve). Odum, reformulated this principle incorporating the idea of energy hierarchy or emergy (Odum 1996); and stated that systems that prevail tend to use all available emergy sources in whatever form they exist (Odum 2004). When translated to man-made systems, such as urban areas, Odum's MPP suggests that, in times of resources scarcity, successful systems would be complex, high-quality, and diverse structures in opposition to more temporary and delicate constructions (Odum 2004). Sciubba confronted Lotka's and Odum's ideas with Prigogine's theories

on far-from equilibrium dissipative systems to reformulate the MPP: prevailing systems tap maximum exergy with minimum entropy generation, in stable boundary conditions for the time period considered (Sciubba 2011). Sciubba's reformulation of the MPP could be reinterpreted as follows in the context of urban systems: in extended time periods, during which the environment surrounding a number of urban areas remains stable, the urban systems that prevail are those capable of capturing maximum useful energy sources with minimum waste production.

These ideas are in conflict with some accepted viewpoints on sustainable design that rely on the first and second law of thermodynamics. According to the maximum power law, as stated by Lotka and Odum, an urban system would tend to maximize its power output, independent of the efficiency of the system's individual parts. The output of an urban system might consist of products (e.g. items produced in a factory), services (e.g. health services in a hospital), information (e.g. designs in an engineering firm), or energy (e.g. electricity from a gas power plant). When these outputs become inputs to another system, the overall complexity of the larger man-made system is increased. However, when part of the output is labelled as waste it means that the system is not capable of further transformation or use of the energy that is still embedded in that output (e.g. food leftovers sent to a landfill instead of a biodigestor). Describing cities as thermodynamic complex systems implies that inflows and outflows of energy, matter and information are accounted for across components, and that outcomes capable of performing useful work can be redirected towards another system or be fed back to internal sub-systems rather than be discarded as waste. In some aspects, these aspirations align with the ones proposed by Cradle to Cradle or circular economy design approaches. The maximum power principle moves beyond these theories and suggests that urban systems that capture more resources can be beneficial by providing more high-quality energy outcomes, but only if they are capable of minimizing the entropy that is generated by the system. This parallel between ecological and human-made systems in the management of energy resources offers a framework for understanding and pursuing environmental design that diverges from the one traditionally adopted in sustainable architecture.

2. IMPLICATIONS OF THE MAXIMUM POWER PRINCIPLE FOR URBAN ECOMIMETIC DESIGN

An ecomimetic design approach that stems from the features described above (i.e. complexity, thermodynamics, maximum power principle), has more opportunities for finding meaningful correlations between ecology and design. Such design approach has also more possibilities of engaging in environmental urban design that is regenerative and resilient.

The idea of understanding urban systems as complex thermodynamic open systems has been discussed in the literature to some extent; however, the discussion of the Maximum Power Principle as a relevant topic for architectural and urban design has not been explored until recently (Braham 2016, Yi et al. 2017b) and deserves more exhaustive investigation. There are two pathways that would need detailed research. One refers to qualitative implications of the MPP for urban and architectural design, and the second has to do with the quantitative tools that would be required to advance research in this topic. A brief introduction to these two pathways is presented with the purpose of beginning a conversation among the design community.

2.1. Qualitative implications

At least, two qualitative properties are key for characterization of urban or architectural systems under the MPP. The first one requires to design buildings and cities prepared to capture all available exergy sources, whereas the second property entails minimum entropy

generation by these systems. This is in direct contradiction to the postulations of sustainable design that aim for maximum efficiency through resource use reduction. At the core of the 'maximum efficiency' paradigm is the non-renewable condition of most energy sources used in human-made systems and the generation of by-products that pollute the overall ecosphere. If open systems, like the Earth system, rely only on non-renewable sources they will head towards thermodynamic equilibrium or extinction; however, if renewable sources are included in the equation, systems can prevail if the consumption rate is adjusted to availability of resources (Sciubba and Zullo 2011). Projections for global renewable energy use suggest a steady increase overall, potentially reaching 80% of energy use by 2100 (Demirbas 2009); although recent studies are less optimistic based on actual performance reported from developed countries (al Irsyad, Halog, and Nepal 2019). Nonetheless, even the most promising scenarios would not be enough to explain why any system should aim for maximum power use in a context of climate change and resources scarcity. However, if the emphasis is put not just on the amount of energy flowing through the system, but instead on the quality and hierarchy of the energy flows, then the discussion can be examined from a complex system perspective. This means that cities using maximum exergy power would be expected to develop a wider network of subsystems (e.g. transportation systems, food production systems, public spaces, educational institutions, etc.) with increased functions capability and increased interconnectivity. These specialized sub-systems would generate higher quality outputs or energy outflows, that in the long term would make the overall system more efficient (Odum and Pinkerton 1955). This means that efficiency would be achieved by increased complexity of the urban system, rather than through energy use reduction. Another important aspect is the cyclical behavior of systems as described by Holling (1992). According to Holling, a system grows and evolves to become an efficient structure, after which some sort of decay will follow before the system can reorganize itself into a more complex, evolved system, or else move into degeneration or devolution. Urban systems also go through cyclical changes that fit within Holling's theory of ecosystems' dynamics. For example, the city of Detroit illustrates the case of an urban system experimenting decline and facing a reorganizational stage that will define if the city evolves into a new prosperous structure or if instead it goes deeper into decay and degeneration (Apel 2015).

As mentioned above, maximum power use is to be complemented with minimum entropy generation. Minimum entropy generation entails that the outputs of the system are in balance, or almost in balance, with the surrounding environment. This means that successive transformations of energy flows follow a hierarchical pathway through multiple subsystems until the final outflow's energy gradient is minimal in relationship to the external environment. Pollutants, floods, or thermal radiation are examples of entropy outputs of a city or thermodynamic waste. These outputs are an opportunity to increase the complexity of the urban system by processing the useful energy still present in these flows. Again, increased complexity of the system is crucial to allow such a refined conversion of energy flows to happen. Researchers have studied and recommended strategies that promote higher urban complexity and minimum entropy generation (Pelorosso, Gobattoni, and Leone 2017). Pelorosso et.al., prepared a list that proposed rain gardens, infiltration basins, green roofs, phytoremediation plants, wetlands, or parks, as low-entropy-nature-based solutions. However, the challenge is not so much in identifying, designing or implementing these strategies, but rather in planning the interconnectedness and feedback loops of these and similar strategies to the overall system. Traditional approaches to urban design, budgetary and

time constraints might explain the inclination to design cities in fragments and pieces, whereas a complex system approach would require that even small modifications should be considered opportunities to enhance the overall system.

2.2. Quantitative implications

In order to design cities that mimic ecosystems' complexity and energy dynamics, reassessment of existing tools and incorporation of transdisciplinary tools is necessary. Emergy analysis is one method to comprehensively assess global energy use in urban and building systems (Pulselli et al. 2007, Srinivasan et al. 2012, Srinivasan et al. 2014, Li et al. 2011, Lee and Braham 2017, Yi et al. 2017a). The majority of the emergy analysis exercises use solar energy as the baseline to evaluate system's energy hierarchy, since the Sun's irradiated energy is the renewable source that is at the bottom of most ecological and human-made systems. Emergy analysis supports a more transparent representation of energy pathways in urban systems and improves energy accountability. Critics to the method argue that calculation of solar embedded energy and transformity ratios tends to be oversimplified, although this is common to most holistic approaches, such as Life Cycle Assessment methods (Wang and Zhang 2011)

System modeling tools are another useful means to design complex urban systems that mimic ecological systems. These tools are especially relevant for their capability to represent the dynamic behavior of the system under study, as well as the positive and negative feedback loops that explain its performance. System modeling tools have been used in several fields including environmental modeling (Ford 2010), but also in the representation and characterization of buildings and cities (Dyner, Smith, and Peña 1995, Thompson and Bank 2010, Shen et al. 2005, Oladokun, Motawa, and Banfill 2013, Garcia-Holguera et al. 2015a) Integrating these tools at the beginning of urban and architectural design exercises would advance qualitative and quantitative research that aspires to mimic ecological systems.

CONCLUSION

Biomimetic design suggests that lessons can be transferred from biological systems to optimize technological systems. Cities can emulate ecosystems and be designed as complex open thermodynamic systems that adhere to the Maximum Power Principle as defined by Lotka and redefined by Odum and Sciubba. An urban system planned according to these principles is one that captures maximum amounts of renewable sources to increase its structure and complexity. Such a city relies on a strong network of interconnected sub-systems that are capable of minimizing waste outputs from the overall urban system by reusing and recycling most of its flows. The more renewable resources the urban system captures, the more its structure becomes resilient and diversified, prepared to face unexpected changes and regenerate when external conditions become stable. In the light of the Maximum Power Principle energy use reduction strategies would weaken the urban system and reduce its complexity; whereas the MPP suggests that, similarly to the phases observed in ecosystems' cycles, a mature urban system would ultimately develop efficiency based strategies and support entropy reduction approaches. Therefore, it is proposed here that maximization of energy flows (i.e. renewable) for increased complexity of urban systems will promote robust and resilient cities for climate change adaptation and mitigation.

Next steps will include the development of urban models using the above proposed tools to test the dynamic behavior of an urban system designed for MPP.

ABSTRACT

Theaters and auditoriums are one of the most important equipment in a city.

The main parameter which determines the adaptation of theaters and halls to their intended activity is the reverberation time. It depends on the shape and size of the enclosure, the materials used in the construction of the enclosure and the way they are built. The absorption coefficient of the materials of a room will be needed either to design it or to analyze its behavior.

The absorption coefficient of the materials in a theater or hall can be determined using the response surface methodology. Its application can be very adequate in such cases in which the functioning of more than one surface is unknown.

This approach can be very inefficient when the unknown material has an extreme behavior (i.e.: very reflective or very absorbent). The reason is the limited range of the increment when coefficients are very small, as the generated response surface area may not contain the target (that would be the reverberation time).

Extreme cases can be better handled with a new approach to assess the real behavior of these surfaces, and therefore of the room, in an effective manner. The adjustment performed will be illustrated through a case study in this paper.

KEYWORDS

Response surface methodology; room acoustics; reverberation time; simulation; modelling.

INTRODUCTION

The adaptation of a theater or music hall to their intended activity is mainly determined by the value of the reverberation time (RT. Reverberation time is the time Sound Pressure Level takes to decay 60dB from the initial value. (Beranek,1996). To recommend an RT value for a specific space, it is used the $RT_{mid,}$ (the mean of RT for the octave bands of 500Hz and 1000Hz). The recommended values of the RT_{mid} of a room depend on the activity that will be held inside. Some RTmid recommendations are shown in Table 1.

Room type	RT_{mid}, occupied seats [s]
Conference room	0,7-1,0
Theater	1,0-1,2
Opera	1,2-1,5
Concert Hall (chamber music)	1,3-1,7
Concert Hall (symphonic music)	1,8-2,0
Church (organ and chorus)	2,0-3,0

Table 1. RT_{mid} recommended values for different type of rooms. Source: (Carrión 1998)

The acoustical analysis of a room can be made by using simulation software. In this study, we have analyzed an Autocad 3D model of the theater of the *Banda Primitiva of Llíria* (Fig. 1) using Odeon acoustic software and Surface Response Methodology (Llinares,2012). This theater is located in the

town of Llíria (Valencia, Spain). It houses the *Banda Primitiva* headquarters and has 1000 seats. The *Banda Primitiva of Llíria* is a musical society with more than 200 years of history; its theater was built in 1951 by J. Rieta architect, and it was refurbished in 1991. First, an on site RT30 measurement has been conducted. Then, a model of the theater has been drawn using 3D CAD and exported to Odeon software. Based on the construction details, blueprints and visual information, we have assigned an absorption coefficient to each surface. The value of the absorption coefficient of a surface varies from 0 (very reflective) to 1 (very absorbent), and it is influenced by the way the material is set in place. Then RSM has been used to adjust the coefficients of the model, in order to make it behave as the real space.

The purposes of the present work are as follows:

• First, to show the possible problems that can appear in the application of the RSM in the analysis of a room, when the surfaces with unknown behavior have extreme absorption coefficient values (near 0 or 1).

• Second, to propose a variation in the RSM application, in order to solve the problem above.

1. METHODS

1.1. Measurement points

This study can be divided into two parts, an on site measurement of the acoustical parameters of the impulse response of the theater and a ray tracing acoustic simulation using a 3D model.

To conduct the on site measurement we have set 20 reception receivers points in the audience plane (non symmetrical in relation to the room axis) (Table 2). The sound source was set in the middle of the apron. There was no audience during tests. Measurements were registered with DIRAC software (DIRAC, 2009); after a file treatment room acoustic parameters were obtained. The mean RT 30 is shown in Table 3.

Centre of coordinates (0) was set in the lower point of the apron, where it meets the audience plane floor (as shown in Fig. 2).

The 3D Autocad model was set inside of a completely absorbent box and then imported to Odeon software (Odeon, 2009). Parameters such as the data of the source, the location of the receiver, the absorption coefficients of the surfaces of the enclosure and the scatter has been typed in.

1.2. RSM in acoustical room analysis

The definition of the variables which define the acoustic behavior of a room can be made by an iterative adjustment process or by the Response Surface Method (RSM) (Llinares, 2012). The first one proves to be useful when studying small rooms or when the researcher is experienced. The second one is a very systematic method, which helps the detection of influential and non-influential variables in the reverberation time of the room. It also allows to obtain data of non-superficial elements. (Pérez et al., 2018). The RSM explores the relationships between several explanatory variables, and one or more response variables. The goal is to use a sequence of designed experiments to obtain an optimal response using a second-degree polynomial. The response, in rooms conditioning, is the reverberation time of the enclosure. To apply this method the absorption coefficient of every surface of the space must be known except for two, the independent variables, whose values determine the response.
RSM can be applied to obtain a study region per surface. Then they are combined to get 9 absorption spectrum combinations.

Study region definition in the RSM application:

$$X_{1i} = N_{1i} \pm R_{1i}$$

Being:
$B_{1i,}$ values taken from the bibliography,
$R_{1i,}$ increments which vary from 0 to 0,5

Analogously X_{2i}

The new absorption spectrum couples are introduced in Odeon to calculate the reverberation time of each combination. The combinations are acceptable when they fit between the maximum and minimum values of the on site measured reverberation time.
Obtained reverberation times are grouped by frequencies, creating 9 combinations of three points by frequency. The response surfaces which fit with those combinations are drawn. We obtain new couples of points from each surface which satisfy the target. We make a Table of the pairs by frequency, and we create new absorption spectrum coefficients combinations of the unknown surfaces. We calculate the reverberation time of each combination, and then we compare the results with the on site measurement.

Zone	Materials	Surface No.
Decorations and curve zones	Plaster frame	1
Stage ceiling, 1st & 2nd floor parapet	Plaster over brick	2
Stage pavement, 1st floor amphitheater	Floorboards over concrete	3
Ground floor pavement	Floorboards w/c	4
Ground floor carpet	Carpet over floorboards	5
1st floor amphitheater pavement	Linoleum	6
2nd floor amphitheater pavement	Enameled concrete	7
1st and 2nd floor stairs pavement	Marble	8
Vertical walls (w/cavity)	Plasterboard w/cavity	9
Vertical walls	Plaster over brick	10
1st floor parapet, ground floor baseboard	Thin wood panel w/cavity	11
Doors	Solid wood	12
Stage opening	Drapes heavy velour	13
1st & 2nd Amphitheatre seats	Medium upholstered chairs	14
Main floor seats	Chairs heavily upholstered	15
Ceiling	13mm plaster on 25mm studs (with mineral wool)	16
Upholstered wall frames	Fabric w/fibers & polyurethane foam	17

Table 4. Materials used in the simulation and number assignment.

1.3. Model settings

Materials used in the simulation are shown in Table 4; a number was assigned to each surface to work with them. Table 5 details the absorption coefficient of the materials described above. They have been taken from bibliography (Arau, 1999; Beranek,2004; Llinares et al., 2012) and from laboratory tests.

Next, the model was proceeded to validation. Parameters of calculation: number of rays: 8221, and impulse response length: 2000ms.

2. RESULTS

2.1. First adjustment

We have taken as unknown surfaces 16 (X_1) and 17 (X_2) (ceiling and upholstered wall frames) (Tables 6 and 7), because they are the surfaces that have a more unpredictable behavior, due to its composition and the way they are built.

Combining the two study regions we obtain absorption coefficient spectrum pairs (Table 8). We will run them in the model to get 9 reverberation time spectrums (Table 9). Note that combination number 5 (tr5) corresponds with the starting values of the model.

With these combinations and increments, combinations are outside acceptable limits (10%), as it can be seen in Figure 3.

2.2. RSM adjustment for extreme absorption coefficient values application

The absorption coefficient of the selected surfaces, has values close to 0 or 1. Due to the way RSM works, the increments we apply are not able to be very high, so we obtain pairs of points which are not very far from the initial considered value. Therefore, the reverberation time of the nine combinations does not get to the target at some frequencies. In this case

Table 9. Obtained reverberation mean time RT30 per combination.

we observed that it was necessary to find a way to obtain the pair of points of absorption combinations of the unknown materials in a more effective way. We decided to start in medium values for the upholstered wall frames (due to its composition, it has the more undefined behavior). We applied RSM again. As these values are 0,5, we could give wide increments (above and below) and study their effect in the nine TR30 combinations obtained.

This way we could visualize which was the influence that a higher or lower absorption coefficient of the unknown materials had in the reverberation times (TR30) obtained for each of them, and how they get close to the on site measurement. If the target it is not contained in the reverberation time combinations, that means the surfaces we have used to combine are not suitable for adjusting the room. Thus, we should choose other surfaces.

After the analysis of the previous adjustment (Fig.4) we have modified increments of the upholstered wall frames at 125 Hz and 500 Hz (Table 10). We have reduced absorption at 125 Hz to make surfaces more reflective, and we have increased it at 500 Hz to make it more absorbent.

With this combination and increments, the values of tr2, tr5 and tr8 for this model are inside the superior and inferior limits at every frequency (Fig. 5). These reverberation times correspond to combinations X11, X12, X13 of surface 16(ceiling) and X22 (upholstered wall frames) of surface 17. We have chosen tr5, as the one that fits better. This combination is shown in Table 11.

CONCLUSION

Some conclusions can be drawn on the basis of the present study. The use of RSM to fit the absorption spectrums of the surfaces of a room can be very useful. It let us work with two unknown behavior surfaces simultaneously. Moreover, it helps us to detect if the surfaces we are considering as unknown, certainly are. In other words, if those surfaces have an influence in accommodating the reverberation time of the room or not. The graphic results provide visual information on which of the combinations, if any, is closer to the real behavior of the room. If not, we can study a different pair of surfaces. Nevertheless,

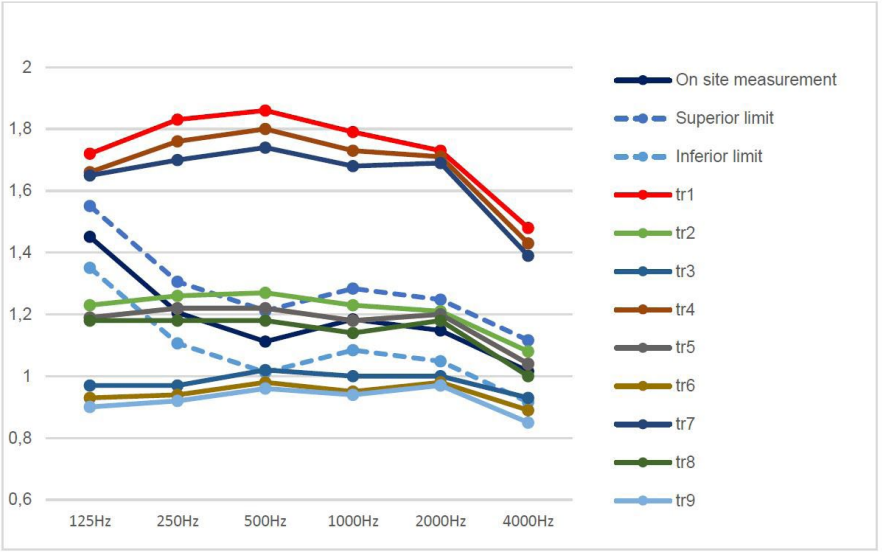

Figure 4. Reverberation time. Adjusted values, compared to on site measurement, initial model (equivalent to tr5), and superior and inferior limits.

Frequency	125Hz	250Hz	500Hz	1000Hz	2000Hz	4000Hz

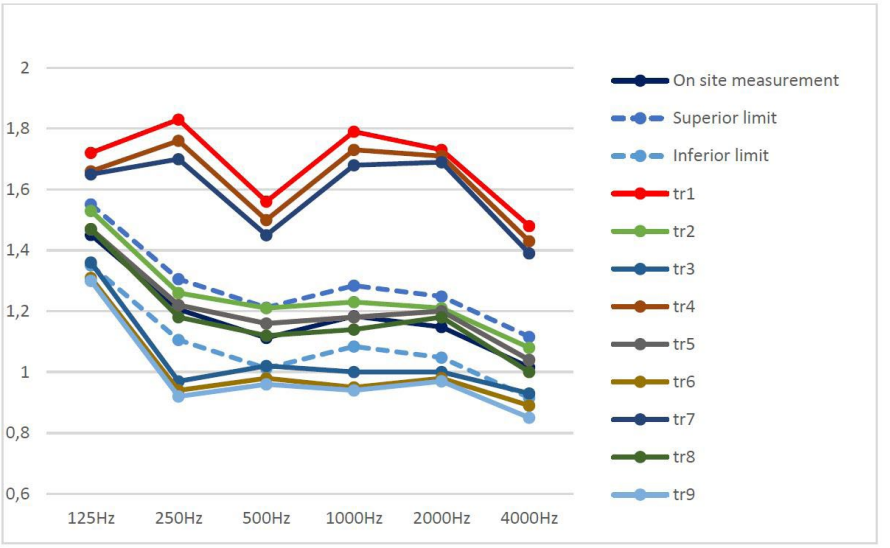

Figure 5. Reverberation time. Adjusted values, compared to on site measurement, initial model (tr5), and superior and inferior limits.

	125Hz	250Hz	500Hz	1000Hz	2000Hz	4000Hz
Surface 16	0,26	0,20	0,10	0,07	0,04	0,07
Surface 17	0,20	0,50	0,60	0,50	0,50	0,50

Table 11. Absorption coefficient spectrum of the materials 16(ceiling) and 17 (upholstered wall frames) that get tr5.

Figure 6. Absorption coefficient spectrum of the upholstered wall frames (before -green- and after -pink- RSM application).

sometimes when the absorption coefficient values of the surfaces are close to 0 or 1, its application could be limited by the own characteristics of the method.

With the adjustment of the method herein proposed, we can adjust accurately the absorption coefficient of very reflective or absorbent surfaces in a more effective manner. It allows to work systematically with the data. It also has a visual representation, which makes interpretations and decisions more precise. The implementation of this adjustment makes it easier to calculate or design a room.

This is a work in progress, so further analysis will provide more conclusions. We have measured acoustical parameters of several theatres, old ones as well as new ones. We will implement this methodology in some of them to check the functionality of the method in practical cases which have different features. Also, archeological acoustic studies could be held in order to find out how those theaters sounded in the past.

PAPER #7.24

PARALLELISMS BETWEEN ARCHITECTURE AND PAINTING; THE REUNITING OF SUBJECTIVITY AND OBJECTIVITY

José Manuel Barrera Puigdollers[a]
[a]Universitat Politècnica de València, Valencia, Spain

ABSTRACT

The architecture of the last third of the 20th century was forged in close relation with the main socio-economic and cultural changes. Through it we can represent its conceptualization. Following Simón Marchan's 1972 book, "From Object Art to Concept Art", we have carried out a research project where we have compared how the main keys of the different movements were transferred to architectural experimentation. We have at the same time represented how the objective and subjective trends were developing, representing a map of their evolution. This paper is the result of that research. At a certain moment, both sequences interfere: it is 'as if' objectivity and subjectivity and other antinomies have a common framework in representative arts and architecture. Identifying this point of confluence, the *symptoms* and, if possible, the keys on which we are working, would allow us to recognize a scenario of opportunity, where there is "a certain possibility to overcome the historic dualities." The critical analysis of this opportunity will permit us to delve into the keys of the split in contemporary thought, the social fracture and the return to the dialectic of confronted worlds that we revive. While we analysis the symptoms, we will also try to present some bases for the reunion.

KEYWORDS

Subjectivity; objectivity; opportunity; possible; impossible.

INTRODUCTION

Architectural inquiry is sometimes exhausted by its very heterogeneity. There are times when the production does not accompany the deliberations, and the nature of objects does not correspond to social, political or economic debates. In other cases the inquiries and proposals are drawn up only graphically or on other plastic supports, with little production, but nevertheless are crucial for their understanding and evolution. There are quite a few authors in different disciplines that have opted for the transversality of sources and knowledge to specify certain shifts or substantive changes in their own. Some cases resort to texts based on transliterations, or analogue, aporetic, metaphorical, metonymic or fixed synecdoche, which make it possible to approach problems in a different way. In others, intervening characters are used that, when they unfold, illustrate a self-referential allocation; Benjamin (like Mercier, Janin, Baudelaire or Larra) focuses on "capturing the picture of history in the most insignificant appearances of reality, in its waste, so to speak", appealing to the passers-by, the ragman (with his hook and basket), the costumbrist, the collector of erotic postcards like Eduard Fuchs, the bookseller, the small tradesmen, the *chiffonnier*, the voyeur, the dregs, "because the dreg of society or poet, both are concerned with trash, both pursue their trade alone in hours when citizens abandon themselves to sleep, even the gesture in both is the same", because "their kind of talent is the same: search, poke around, own what belongs to others". And in other cases, the precise study moves to other activities

of parallel route; how Benjamin articulates his aesthetic proposal, around the dialectical gaze; Aby Warburg's *Atlas Mnemosine* which, managing images organized according to small details, allows the reconstruction of culture from the parts to the whole; the proposal of *factography* or *operating* author illustrated in Tretyakov, which encourages action and the work involved in the project; the *dialectic in a state of detention*, or the *principle of Interruption* and *estrangement* deduced from Bertolt Brecht's "Epic Theater" that Benjamin will recompose from a social perspective as a *re-functionalization* of art and that he will understand as chosen from the *montage* praxis that allows going into the scene of the *gaze of the outsider*[1]. In addition, the graphic-poetic proposal of Mallarmé (2016) (for whom "saying is not only expression, but the development of thought") continued -among others- by Octavio Paz and that from the graphic design of the text a priori induces reading to the subject's unconscious, predisposing meaning (Benjamin 1992, 141). Or the transformation of Soviet art in its second stage, shown in the figure of Lizzitsky, against the aestheticism of politics, starting from the politicization of art as Paul Valery pointed out; but it also shows participation in the work and the breakdown of the aesthetic residence framework.

1. THE PRODUCTIVE LIMITATIONS.

As Lord Chandos (Hugo von Hofmannsthal) confessed in a letter to Francis Bacon in 1902, the impossibility of language to communicate, in the emergence of postmodernity perhaps the same thing happened to us; the impossibility of seeing in the production of the architecture itself and all its unfolding, having to go to other references of images, while these *open the revealing event of the transit of history*, in a clearer and more explicit way than in that. And this is precisely at the moment of entering the most textual period of this history that took place in the 70s, when Bernard Tschumi used it in "Joyce's Garden" his urban project in London in 1977, based on the novel "Finnegan's Wake" by James Joyce; or Peter Eisenman in his Even Odd House , working in forms of "L" that challenge the concept of subject centrality and security; or in Cannaregio in Venice in 1978, where the text as overlapping layers justifies the work, or the Long Beach University Museum of Arts, where he uses a fragment of the George Orwell film, "1984", imagining three simultaneous time periods: 1849, inspired in the race for gold, 1949 on the occasion of the creation of the Campus, and 2049, when the campus would be archaeologically rediscovered from its ruins by a successor culture, explaining vestiges of different times, because there is no history except for the unrecognizable scattered objects. Also John Hejduk experiences it with the masks, and his references to Benjamin (Hejduk 1986). These complexities become architectural objects or devices, sometimes surreal, others fictitious, others very particular or intimate. They are mental constructs, recurrent as important themes (Hejduk 1986; 1985); others call *densifiers.* Solà-Morales (1990, 85) already puts forth this problem: "the linear conception of history as unlimited progress of humanity was destroyed by structuralist thought". Such transformation and affirmations could infer that everything went the same way in any discipline. Given the difficulty of seeing their transformations in the same production and to verify the accuracy of this statement, we approach another discipline: the text by Simón Marchán (1986), because it details a total of 24 consecutive pictorial movements in a scarce time span of three decades 50s, 60s and 70s; descriptive rigor hardly visible in the architectural field that will allow us to unravel the problem.

[1] Estrangement is equivalent to showing a subject his face in a mirror, but where such an image can now be detached from him and transported.

2. OBJECTIVE

To carry out the research in parallel with both disciplines, conceptually review the period of transition from structuralism to post-structuralism, representing on various cartographies the parallelism between painting and architecture at this time. Detail will be given where determining circumstances occur, outlining novel records, so that we can pinpoint their precise circumstances and check whether certain claims by critics and historians about this time of change are consistent.

3. PROCESS

To address the specific period where this dissent arises, we elaborated a concept evolution map. We take the pictorial field for being the widest, most susceptible and experimental, where this modulation is visualized most effectively in its transits. In it we observe that the two main lines of work that take shape before and after the Second World War, the objective and the subjective, present a point of union that could have meant a reuniting or dialectical balance between opposites but that was finally divided with a more emphatic distancing. In what follows we address the two numbered lines by temporary sequence, although in art history these impeded delimitations in evolution are mistaken for their amplitude and interconnections with others, except for the origin of their statement.

4. METHODOLOGY OF WORK

Creating work records that relate concepts of painting and architecture and the comparative analysis of conceptual cartographies of painting and architecture, and of these with: a) cartography of philosophical currents of the second half of the 20th century; b) objectivity-subjectivity mapping. The process is the following:

Each of the 25 participants in the two courses have identified each pictorial movement[2]. In each file the specific variables

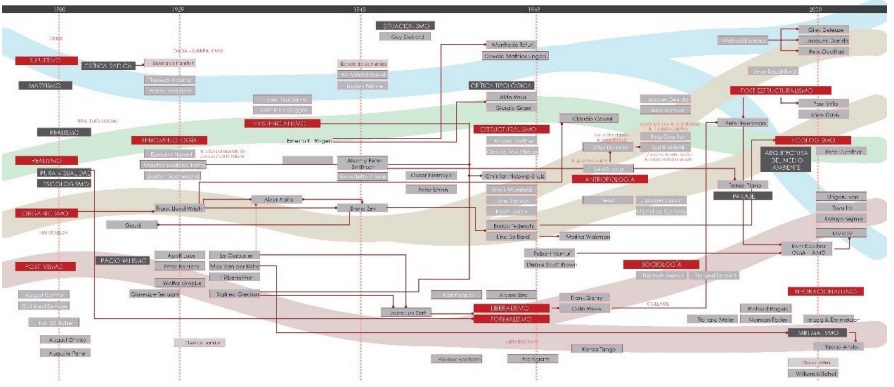

Figure 1. Mapping of evolution of philosophical currents in relation to architecture. Source: Master Degree in Barcelona from Josep Maria Montaner, updated and reviewed by the author.

[2] (1) new figuration, (2) pop art, (3) neo-surrealism or fantastic imagining, (4) psychedelic art, (5) surrealism and hyperrealism, (6) social realism, (7) neo-Dada to shocker pop, (8) narrative imagining and critical social reporting, (9) overcoming informalism, (10) concrete art, (11) new abstraction, (12) minimal art, (13) optical art, (14) kinetic, lighting and real movement art, (15) computer art, (16) collage and object art, (17) art of ludic spaces, (18) happening, (19) Fluxus, (20) arte povera, (21) land art, (22) mythology, (23) art of behavior, (24) conceptual art.

are highlighted and establish a relationship with the architecture in a way that the architectural project selected responds to the same variables highlighted in visual arts. As they are all different, we have a sample of 600 files from the 1,200 carried out. We find a period between 1965 and 1980 where certain movements cross since their revisionist objectives concur. Some with more participatory approaches, others more ludic-ironic, but they coincide in showing a change and transformation with respect to the established socio-institutional parameters. We take as guide the subjectivity-objectivity relation that guides the rest of the antinomies.

We confirm the unfolding conceptual philosophical underlying each example, provided there is relevant data to clarify it. Starting from the cartography of the Master Degree of Josep Maria Montaner (fig. 1), revised with different updates, we differentiate its proximity or belonging to four basic conceptual bodies in the relation between architecture and philosophy: subjectivity, realism, organicism, and positivism, existing in the 20th century. These evolve as follows:

- *Subjectivity* articulates critical materialism, it contaminates with situationism, a certain typological criticism, environmentalism and post-structuralism. Since the 70s it has been divided into two lines: criticism of the critique or *kulturkritik* (cultural criticism) and the more subtle line, neo-structuralist and environmental, creating atmospheres that cut off all other movements. Currently, certain central European neo-constructivism attests to this.
- *Realism* connects with phenomenology, existentialism, structuralism and ends connecting with a certain ecology or environmental architecture. It remains unified and constant, with periods closer to subjectivity and others to objectivity, depending on their representatives. Its journey is cut short by the fluctuations of the others.

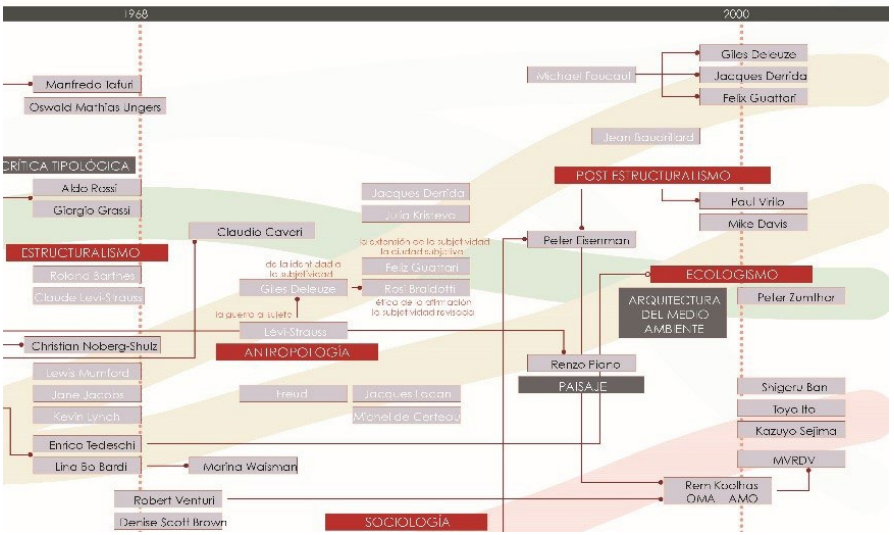

Figure 2. Detail of the study period together with the 24 pictorial movements described by Simón Marchán. Source: author.

- *Organicism* has a parallel evolution to the previous one, but it shows a split in the 1960s: an anthropomorphic and anthropological line that becomes critical and coincides in the critical premises of subjectivity, and another more ecological, feminist and continuist.
- *Positivism* connects with rationalism, technique, science, liberalism and formalism. But around the 1960s it divides, a continuist line on the primacy of science stands out with minimalism, and another somewhat more critical current, which approaches conceptual positions of subjectivism that separate. All this is visible in fig. 2.

We discover in the same period that the area of study 1965-75; various overlaps and crossovers of the continuous lines occur, making various concentrated dualism in this period clear: structuralism-post-structuralism; identity and autonomy; subjectivity-objectivity; formalism-interpretation; realistic evidence-abstraction; presence of the other-absence; instrumental reason-dialogical reason.

Later in the group work we select the most relevant concepts of each movement, creating a synthetic matrix. From this and in view of the 25 examples of each movement we identify the objective and subjective priority character of the samples, both plastic and architectural. In the lower graph we identify in grey the process of the most objective movements and in orange the most subjective. They barely coincide with each other in their development, except in a brief period, since their distinction is relevant to start with.

On the one hand, the objectivist, formal and figurative line integrate it: (1) new figuration, (4) psychedelic art, (8) narrative imagining and critical social reporting, (9) overcoming informalism, until reaching (15) computer art. It is at this moment that the limits between objectivity and subjectivity are no longer precisely defined and their margins are interrelated: with (16) collage and object art, (17) art of ludic spaces, (18) *happening* and (19) Fluxus, where progressively in these four subjective designations in origin the objectivity is implemented to the detriment of the assortment of previous subjectivity. It continues (20) *povera arte*, (21) land art, and (23) art of behavior, where despite its statements in its praxis, a dominant objectivity is sought.

On the other hand we highlight the most subjective line; (2) Pop art or the art of popular image, (3) neo-surrealism or fantastic imagining, (5) surrealism and hyperrealism, (6) social realism, (7) the transition from neo-dadaism to pop shocker, (10) neo concrete art and European structuralism, (11) the new abstraction, (12) minimal art or primary structures, (13) optical art as visual provocation, (14) kinetic-light art and real movement, up to (15) art and the computer, where the objectivist contamination begins. They are followed by (16) collage and object art, (17) ludic spaces, (18) the happening and (19) Fluxus, where the subjective tendency in favor of the objective gradually declines. It continues, (22) the art of mythologies

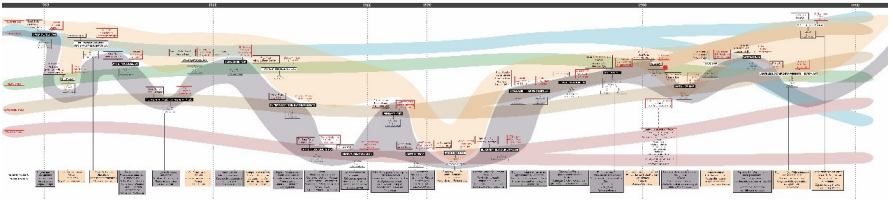

Figure 3. The mapping of objectivity and subjectivity, in the period of study. Source: author.

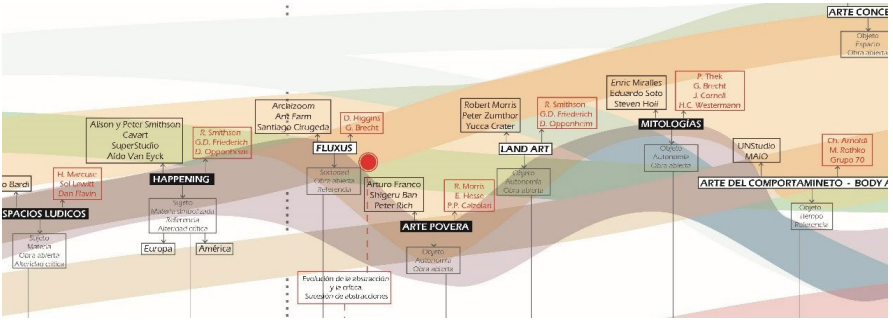

Figure 4. Detail of the overlaps between objectivity and subjectivity in the study period, overlapped with the mapping of philosophical trends and outstanding creative and cultural events Source: author.

and new reductionism, until reaching (24) conceptual art.

We find in the same period a concentration of social and political upheavals where objectivity and subjectivity merge, like the other antinomies, because they are not the priority objectives of representation or architectural formalization. Around the movements (16) to (22) there is an overlap, which is later separated in conceptual art (24). In these movements, art is used as a critical conceptual display tool with the intention of covering new registers and experimental territories, avoiding previous debates. Architecture assumes artistic assumptions, even promotes them by championing trends. In this way the dragged dualisms and antinomies are displaced to their irrelevant place. Performance, activism, participation, socio-political-economic discourse, including debates on gender and feminism, are given preference. The need for desire, experience, experimentalism, the sensitive to the sense.

This sociopolitical-cultural scenario in the interlacing period was dominated by the rise in sociopolitical activism: the debates on multiculturalism, the feminism of "the women's building", and the problems of AIDS, or sex workers, etc. In this context, identity activist proposals that are key in these political analyses dominate, based on the awareness of the identity of origin and the identity of the public, examining the ways of personal representation from fractional perspectives: personal relationships/roles; narration/autobiography; body/beauty; daily life/costume; community identity/forms of power. On the other hand, multiculturalism provokes a participative dynamic with art, where minority groups and associations achieve an excessive prevalence (Gran Fury, WAC, Guerrillas Girls, etc.). They are verified in: great organizational activity, collective and impersonal practices, with mass media techniques: as a stimulus through interpretation, or as provocation, controversy and public debate. With the borrowing of public space and topological occupation by community movements or community-based art (Lippard 1984, 34). In an effort to encourage collaboration with the community, sometimes seizing their space-time, with protesting techniques, mural pickets, graffiti, etc. with theoretical supports such as Freire (1972), Dewey (1994) and Connor (1996)[3] who encouraged day-to-day experimentation with their environment, criticizing marginalization, taking a gamble on neighborhood centers, challenging violence and extreme poverty promoting the re-socialization of marginal sectors, interventionist intentions and appropriating themes such as environmental, ecology, social justice, neighborhoods or

[3] From the conceptualist critique of art institutions.

democracy. In them, society participates as co-authors ("Culture in Action" 1992, Chicago).

Mapping the overlap: we try to look into what content is relevant in the specific overlap period that we have identified. We check the following conceptual sequence (fig. 5):

a) The interventions of the Smithson, Cavart, Superstudio and some of Aldo van Eyck parallel to the visuals of Smithson, Friederich or Opponheim, who promote the *happening* coincide in focusing attention on the subject, the symbolized matter and a certain critical alterity, but this comes from his political assignment, as a parallel decision of the author. This prescribes a matrix with the following terms; the work elements constitute actions; the artistic product is isolated; it is necessary to make it visible in the political context; the approach is social, material, responding to the premise of art and life and generating symbolic criticism.

b) And this scenario converges in other interventions by Archizoom, Ant Fram or those integrated in Radical Architecture (Celant 1972), with plastic works such as that of Higgins or Brecht. It is these actions that connect with radical position of **Fluxus**, centered on the primacy of society, the loss of individualism, the complete development of the Open Work, and the reference to the previous as well as distant. Its objectives were the creation of *improvised events,* as well as the elimination of the traditional concept of fine arts, replaced by showing the ways of social life. Also the search for participation in the work, so that the viewer clarifies it, or acts as an author redefining it, thus showing a certain anti-art character, and putting the emphasis on the artist's training, not on its cataloguing by critics of the institutional *status quo*.

c) It is followed by **povera arte**, with interventions by Arturo Franco, Shigeru Ban and Peter Rich, and visuals by Morris, Hesse and Calzolari. Its aim is the search for a residual object exemplified as criticism, without reaching the formalist "objectualism", from the autonomy of the work and displaying the content of the open work, while the user enters and penetrates the work clarifying it, but also in its abstraction, taking over as an interpreting artist. Its ultimate aim is the loss of culture of the image, poor or low-income art, ecology, the introduction of social connotations, the reaction against the technological world, and working with the surplus of society, recycling while consumerism is challenged. All art from this period is political.

d) In line with this, **Land Art** is developed, which occupies a similar place, but in territorial terms. This increase of scale assumes the implications of sustainability, environment, criticism of productivism and naturalistic return. With interventions by Robert Morris, Peter Zumpthor and Yucca Carter, and plays by Smithson, Friederich and Opponheim, with similar objectives as the previous

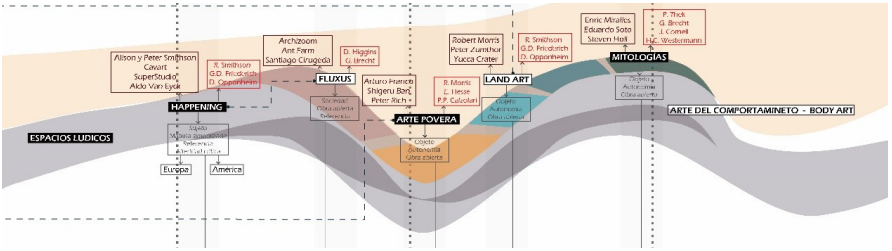

Figure 5. Concept map and its evolution in the period of overlap between objectivity and subjectivity. Source: author.

one. However, the context is natural, fitted around the physical-mental axis, through an illusory image, sometimes temporary, with a metaphorical proximity, about the statement of time as a basic condition of the work and as an exhibition of a slight durability, as a metaphor for the destruction of the planet. A critical underlying layer that link to the previous one.

e) They follow in the **mythological** direction, hand in hand with interventions such as that of Miralles, Soto de Moura, or Holl, and plastic works such as Thenk, Brecht, Cornell, and Westermann. Their objective is the search for a symbolic object, from autonomy and open work, similar to the previous two and whose purposes are: the search for experiences in relation to knowledge, apply personal ideas, the creation of a particular creative world, through instrumental individualism, of a plastic-pictorial nature, with a multiplicity of chromatic *experiences*, for the sake of a psychic constitution.

5. IDENTIFICATION OF OVERLAP

From the perspective of thought (fig. 4) the overlapping figure is a rhomboid that is located between the two branches of organicism at its intersection between realism on the left and one of the branches of subjectivity on the other Kristeva, the lower vertex the most anthropological up-to-date with Strauss and Gilles the Munford, Jacobs, or Lynch and the right vertex of ecology-feminism, with Derrida, Jean Baudrillard, and Guattari. The figure supporting psychoanalysis is with Freud, Lacan and Certeau. Thus we see a horizontal transition from structuralism to post-structuralism and vertically the transition from ethnography and anthropology to environmentalism and feminism. In the middle, three factors link these proposals: (1) The different approach to hermeneutics from the open work, (2) the different reading of alterity, (3) the different reading of ethics and social-ethics (Navone and Orlandoni 1974; Tafuri 1972; Koenig 1971, 19).

From the aesthetic conceptual perspective the following meeting points are appreciated: a common evolution of abstraction and criticism as a linked discourse, through a succession of abstractions and overlaps that make a cryptic discourse about time that enriches it in a manifest way. Linked in three textual resources:

1. Shift from semantic primacy to syntax: it is the beginning of the questioning of the process of revelation, work and unfolding of content; due to the difficulty of understanding meta-languages compared to the subtlety of the poetic approach to constructive syntax; by introducing new work processes from the action, or prioritizing the activism that can be carried out with the work, taking hermeneutic, interpretive and transcendent action as ideal. The introduction of the temporary twist that better channels the syntax of the hypertext.

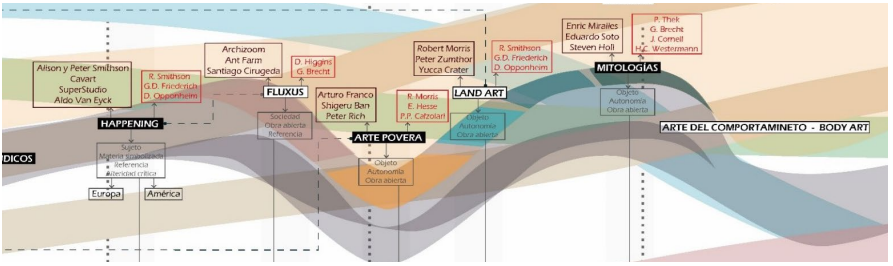

Figure 6. Detail of the previous figure on the map of philosophical trends of the period. Source: author.

2. Semantics aims at a morphology that is directed towards meaning and results in *repertoire*. The incidence of other people's discourses trivializes the ethical-social achievements.
3. The syntax does not claim morphology, it is polysemic like poetics, it uses other logics of meaning from the alternative, by introducing alterity, and it is based on the *systems of connections*; references, experiences, interactions, energies, flows, establishing prevalence to *relational systems* that foster inter-subjectivity, synergies, links, agreements, the basis of a new non-capitalist modality of the collective. Here culture continues to have an articulating, critical and art-related role, without prejudice to its contemporary reading of showing ways of life.
From the architectural perspective we find works such as: on the left vertex Lina Bo Bardi, Marina Waisman and Claudio Caveri. The centre is held by Eisenman with his entire repertoire, Libetskind, Coop Himemblau. Diller and Scofidio. The top vertex is Yunga Ishigami, Souto de Moura, or SANAA in their most inventive contributions. On the right is Peter Zumpthor, Lacaton and Vassal and more to the right Shigeru Ban, Toyo Ito and other works by SANAA. Below MVRDV, Rem Koolhaas, Nouvel and Piano.

6. ANALYSIS AND KEYS TO THE FIGURE BETWEEN 1965-75

This period links six transformations that articulate in their incomprehension or deformation, a paradoxical occurrence: (6.1) culture, as an abstract of the representative arts becomes the demonstration of the way of life of society. Culture and society were united and with *mass media*, only society is shown, without entering into its criticism, showing the superficiality, which is enough to become real. This leads to alienation, simulation, phantasmagoria, vulgarization, and loss of judgment. (6.2) The personal is political (Hanisch 1970), proceeding to the sexual is political, the private is political, creative particularities are public and political. With this, the micro-stories become political. This leads to personalisms, identity, their weak history, fallacies, and the substitution of reality for personal stories, not useful for society as a whole. (6.3) Activist art becomes activism as art. This stifles the ability of art to establish signs, because it refers them to group demands and with it to inorganic multiplicity. On the other hand, activism generates aesthetical signs that make cruel speeches full of ignorance. Thus the aestheticization of the masses is art and every collective act establishes culture. This converges in micro-stories, paradoxically based heterogeneity, subjectivism, politicized participation, absence, dispersion, hypertext, parataxis, and desire. (6.4) Postcolonial theory brings with it ethnography, fetishism, cosmopolitanism, methodological nationalism, a cosmopolitan reconstruction of history, and a new nation-state theory. And with it, comes evanescence, destructuring, ghettos, multiculturalism, urban tribes, multiple identities, the glocal, the anti-form and the process. (6.5) The break with state institutions, power and productive systems, through a misunderstood materialism. This gives rise to radical architecture and Fluxus. It causes a transition from the search for meaning to experience, and when experience is sensed, reality is replaced. This brings with it the disintegration, fragmentation, rupture of the order, overlapping of layers, the fungible, the transitory, the surprising, the performance, the event, the imaginary and the aesthetic anarchy. (6.6) The separation between culture and society, which leaves a gap and is occupied by politics. This leads to a superficial approach to real problems, thanks to opinion-makers, moving this political predominance to ideology. In this way everything becomes a cause for struggle, with a loss of overall vision. This brings the primacy of inconsequential stories, relativism, empty transversality,

[4] In the debate at the Goethe Institute of Paris (April 1981), between J. Derrida and H. G. Gadamer (1977), on the scope, the limits and the perspectives on interpretation.

death, loss of reference, loss of meaning and disproportion between causes and effects.

All this converges in the hermeneutical differences of both synthesized lines (Santiago 1999), in that debate between Gadamer and Derrida[4],, with the following signs: 1) inter-subjectivity in the face of textuality, 2) dismantling versus disassembly, 3) the conjugation of the "we" as a result of social agreement, aimed at consensus, versus conjugating the "we" as teleology. This dual understanding of interpretation goes hand in hand with differences in **alterity**[5]. Alterity, or introspective thinking of the other, stands against the search for the unity of being or to affirm the totality that denies becoming, the difference and the appearance. Both general hermeneutics and deconstruction start from a common basis: they either deny the immutable and stable character of thought that excludes the other or rather are inclined to think about it; but it in two directions as we pointed out:

1. The *dialogical* based on "inter-subjective" relationships to understand and reach consensus, which leads to integrating the other, as I understand it. The alterity, being the relationship with the other, is and happens in language: therefore, it is not consumed in language, but preserved. This is its **ethical** dimension. The interaction with the other in questions and answers, establishes a negative experience that allows understanding to happen. Understanding is experience in language, where the question transforms the meaning of the world that we have. It is self-understanding, a rational reconstruction under the sign of the conditions of acceptability that finds in the confrontation with alterity the impulse that prevents it from being precise and that maintains it in transformation. The conversation was related to language and tradition, which pave the way to unraveling it. A conversation as the development of understanding is the relationship with the other, where face to face with alterity introduces us into it, renewing our assumptions. This is how the idea of the world is unraveled, since there is only a world in language, in which both are bound together from the beginning. Permanent tension between the intangible other in unity and understanding.

2. For Derrida the occlusive manifestation of logocentrism and the revelation of the metaphysics of its presence is the same. For *deconstruction*, by making an effort to integrate the other into my significant registers, I fold it into my personal comprehensive structure; and this, because I nullify the "difference" irreducible between subjects, questioning it, since it starts from the impossibility of integration; that is, it is an other that does not enclose me. For this reason, alterity is singular and heterogeneous, it is difference and a non-presence that is not welcomed in the language that seems rather to be contrary to it; its emergence is an event that creates the concept, but it is not included in that way, it always remains heterogeneous. Thus, the event is the impulse that calls for the recognition of the other, it is justice. For justice is the impossible event, (the force of which is *differance*) in which alterity transgresses and creates the concept without including itself in it, it is the impulse of the other that strives for its recognition, but whose introduction into language will be nothing but the attempt to welcome it and limit it by excluding it.

Thus their differences are irreconcilable; the dialogical position of understanding or consensus, and the deconstructive, where the tension between the intangible other in unity remains; or also, *the difference between the language of the event and the event of language*. Which implies two readings of hermeneutics and open work: (1) the prefigured (in its functional order) that leads to consensual

[5] Its root alter (other) and suffix -dad (quality) = condition of being another, discovery of the conception of the world (formed by "us" and "them"), specially the interests of the other, to introduce the perspective of the others in their own. "From the perspective of the other, the self that in each case is mine or yours, is also another" (Ruiz 2007). Pedro Laín Entralgo (1966, 396), points out that the pronoun "we" is a key term that integrates the themes of ethics (justice, love, friendship and communication), social philosophy (history, civilization, tradition, community), epistemology (conditions of possibility of the encounter or discovery of the other), anthropology (theory of the self), etc. Levinas (1995, 67), points out in 1971 regarding the otherness: "the estrangement of the other –his irreducibility to the self, to my thoughts and to my possessions– is carried out as a questioning of my spontaneity, as ethics".

solutions within a tradition of typological schemes, providing systemic resources waiting for an unsuspected but homologable solution to come ; and (II) -the not prefigured, which obviates the a priori consensuses rejecting the types of history, which subverts the established order to accommodate other forms of inhabiting, erasing the pre-constituted relational sense and allowing the unsuspected, the contamination. Three types of alterity are given:

1. Instrumental alterity (Frankfurt school), restrictive position of the interpretation limited to the world of the author's life and his knowledge. It empowers the pragmatic social agreement, and is based on "it knows that it knows" and "does not know that it knows", where causes and effects are proportional.
2. Ethical alterity (Umberto Eco), open position limited to the author's significant context and with ethical reference. It empowers the renewed social agreement and is based on the "does not know that it knows" where causes and effects remain proportional.
3. Ethical and socio-political alterity (Derrida), position that admits contamination of an unlimited nature, where forbidden or grafted meanings may concur. It empowers a new social agreement limited to what is possible, and is based on 'does not know that it knows', where on the one hand the effects are superior to the causes, the emerging of the event (also fantasy); and on the other hand, the causes are superior to the effects, where the event is forced, achieving the anti-event. In the first ones, the real is enriched with fantasies and in the second, reality is equated with fantasies, creating a virtuality of meaning, or an emotional experience taken as reality.

CONCLUSION

The reunification between subjectivity and objectivity occurs in architecture within the field of ethical alterity, in its two variables, especially in its socio-political, not necessarily ideological dimension. Their chance reunion implies to ethically face the paradoxes previously stated to break them up, modulating the unification between culture and society with the integration of the Other. This articulation is integrated with the *experiential and temporary architecture,* in a social poetic key, where syntax prevails over semantics, which in its pointless eagerness derives in activist political discourses. These would be the keys to return to disappearance of dualities and opposites, while we weave not only an art that is inclusive, sustainable and protective but also an equal society.

PAPER #7.25

VIRTUAL ARCHITECTS: ANALYSIS OF DYSTOPIAN ENVIRONMENTS IN VIDEO GAMES

Luis Miguel Ramada Peiró[a], José Manuel Barrera Puigdollers[a]
[a]Universitat Politècnica de València, Valencia, Spain

ABSTRACT

In the last forty years, video games have undergone an important development and are set to become one of the most important cultural phenomenons in the 21st century. This work will analyse the role of the so-called *"virtual architects",* in the creation of video games and in the design of the virtual worlds through the study of six video games. Three of these games are representative of the main contributions in the immersion of the player as the regulatory principle between the real and virtual world; a study of the video game as an artefact outside itself will be carried out from an aesthetic perspective. The remaining three, as examples of the creation of dystopian virtual worlds full of symbolism and able to adhere to the collective imaginary; the video game as a virtual world of the player or for itself will be studied.

KEYWORDS

Virtual architects; video games; immersion; dystopia; aesthetic.

INTRODUCTION

On the 3rd of November 2018, the world Championship of League of Legends registered a peak of more than 205 million viewers. It became the most watched eSport event in history, almost doubling the sporting event *par excellence* in America: *Super bowl* (110 million viewers). That same year, the video game industry exceeded 140 billion dollars. In the free market it reached almost 30 billion dollars, three times more that the cinema and six times more than the music industry. [1]

These data are used as indicators of a reality that we have the opportunity to witness: the video game, a contemporary cultural artifact, a generator of experiences and pleasure, a developer of meanings and ideologies and narrator of theories and stories, on the way to becoming the most important cultural phenomenon of the 21st century. Perhaps for this reason, on the occasion of the publication of Alfie Bown's *Playstation Dreamworld*, Zizek states:

> The universe of video games and the action they involve us in render perfectly the illusions and antagonisms of our ideological predicament: the popularity of post-apocalyptic games tells it all. But perhaps even more important is the type of subjectivity a gamer has to adopt when immersed in a game: a mixture of extreme engagement and loss of reality, a universe of immortality where actions are indefinitely repeatable. So is not that we can understand the impact of these games only thought the analysis of our social reality, it´s also the other way around: to understand how our societies work you have to know video games.

Although in its relative infancy, this cultural phenomenon with just over 40 years of experience, has not yet explored its full potential. It is the most complex and elaborate manufactured world among those existing in relation to the creation of virtual environments. As a result, it has already been

[1] According to eSports Charts; consulted on 19 October 2019.

an incipient object of study from different perspectives.

Along this line, the aim of this article is to approach the study of the video game as an artistic artifact, taking the role of the virtual architect as its central point. In order to do this, two paths will be taken: first, the regulatory principles of the game will be considered as a virtual world outside itself, its physis; a task that will be developed from the aesthetic perspective, that is, through the dialectical relationship between subject, object and aesthetic experience; and later, the praxiological principles of the game will be studied, as a virtual world of the player, or for itself; its *praxis*. Or, to put it another way, and paying attention to the architectural key: firstly, the video game will be studied as an artifact through different titles already considered classic and were pioneers in the use of virtual space. We will see the decisive role of virtual architects in the immersion of the subject as a condition of possibility of aesthetic experience. Secondly, the mechanisms of power in the biopolitical sense that the video game incorporates as a virtual world will be identified, through the analysis of the cities created by virtual architects as possible horizons that shape the mechanized imagination, also from titles that are typified by the incorporation of virtual urban environments or dystopian cities. In both cases, single player video games will be taken as the object of study, since the interpersonal ones exceed the capacity of analysis given the extension of this format.

Before delving into the two approaches, it is necessary to explain what we mean by *virtual architects*. In general terms, the game design consists in processing design content (characters, scenery and surroundings), the storyline (background, plot…) and the rules (the do's and don'ts and what the programmed response is to such effects) of the videogame. Due to the complexity of current productions, this is clearly not a one-man task, not just one game designer; it is a process in which dozens of multidisciplinary teams come together. The area in design teams that interests us for the case are those who design the levels; embodied in the figure of *level designer*. This is the area of available space for the player in order to reach his objective. Starting at a level, the player interacts with the game in question, being faced with a series of objectives and challenges, which determines the degree of immersion in the experience. Virtual architects are those professional team members who are responsible for designing virtual sceneries for video games, paying special attention to the design of urban surroundings. It goes without saying that strictly speaking not all virtual architects are architects, although there are many and well known examples on the subject.[2] This however, is not of interest to us: the issue here is that the tools of some and others and consequently, their mechanics are usually the same (computer-aided design, 3D modelling or rendering and therefore operations of addition, subtraction and repetition…). Therefore, the video game industry has become a possible future for many young architects to consider. This could be the reason why virtual architecture is an object of analysis from the discipline and assess which architectural mechanisms are available when creating video games. Furthermore, the difference that separates those who design in the real world and those who design in the virtual; some are affected by all kinds of conditions and for others; the only obstacle is their imagination. This turns video games into a very fertile ground for materialising other possible worlds, dystopias and utopias steeped in symbolism and able to become part of the collective imaginary.

[2] María Elisa Navarro in the development of Assassins Creed 2 or José Sánchez in the development of Block´Hood

1. AN ACCESS TO THE VIDEO GAME FROM AESTHETICS: REGULATORY PRINCIPALS

1.1. The immersion: regulatory mechanism of the player's experience between the real and virtual world

The analysis of the video game is carried out from an aesthetic perspective since it will allow us to understand the particular relationship between the subject of the aesthetic experience and the work of art or artifact (subject and object), to later examine the role of the virtual architect in this relationship. In this way, we will be supported by the genealogical-transcendental research done by the philosopher Joaquin Siabra Fraile of noticeable *Hegelian* influence. If the question that arises next is, whether the video game can be effectively considered as an art form but providing an answer is not the task to be addressed by this work (although *MoMA*'s decision in 2012 to add a selection of 14 video games to its permanent collection could be mentioned). The question is quite the opposite: it is whether or not the video game can allow the player to have an aesthetic experience.

To that end, it is of interest to clarify the terms in which the question is formulated, as has been pointed out, when we talk about object or work, we speak of the video game and when we speak of subject, we do not refer to anything other than the player. Although, when we refer to the possibility of an *aesthetic experience*, we refer to the simultaniety of two conditions: the first is that there is a *psychogogical* component, and the second is that there is a certain distance between the subject and the object that allows understanding, the amazement or merely the appreciation of the work by the subject.

In this case, the *psychogogical* component is the storyline, that is, the ability of a video game to tell a story, to relate a series of events that occurred with a certain timeframe, and in a specific setting.

Regarding the relationship or distance that takes places between player and video game, we observe something particular: the player is not a mere spectator of the work, as might be the case in a theatrical performance. In fact, he participates in the evolution of events, his decisions mark the storyline, therefore, and he is not strictly outside the work. But he is neither an actor nor a dancer, there is no *libretto,* that is, the decisions he makes, he makes freely, he does not try to represent a scene that is written anywhere or follow a choreography. In this way, the work is no longer set and closed to be represented, but the player's actions have consequences in the plot and are being developed: it is, in effect, an open work. What articulates this mechanic is the model: a series of rules that allow or restrict player actions and determine the responses from the video game that are given to such decisions. Is the player, therefore, strictly within the work? Is there any distance between them?

So far we have seen two basic components that define the video game: the storyline, and the model. But it could certainly be argued that they are not exclusive to it. We could talk then about role-playing games, or about the choose *your own adventure* books. In both, there is a system of rules with consequences (model) and also some events over a period of time in which the character is involved (storyline) being able to alter his course by making decisions. However, it is clear that in neither case a degree of aesthetic experience like that achieved in video games is reached. While in role-playing games, the director of the game can introduce an interesting story and through a roll of the dice the subject's decisions have an impact on the world of the story. It is precisely the figure of the director and the figure of the dice that make it clear to the player over and over again that everything is a simulation. On the other hand, the number of different possibilities in the story that a book allows is limited by its format. Synthetically: in the first case, we see the storytelling of

the model, in the second, the modelling of a storyline. The video game increases the complexity of the second case due to the technology it incorporates, that is, the model as a computer program. But the way in which it resolves the conflict of the first, is the one that leads us to the role of the virtual architect, and the one that, somehow, answers the questions that were asked before. What is the relationship between subject and object that takes place in the video game?

The particular relationship that exists between the two is what is referred to as *immersion:* this being the relationship between subject and object by which the subject is presented within the work, but without integrating with it. He is not, in short, an actor, neither spectator, but both at the same time. In other words, the subject is within, but is capable of recognizing itself, since he also recognizes the work. In the immersion the subject lives the experience that his actions appear to him as belonging to an autonomous artistic *physis* (or virtual nature with its own laws). Through an interface, he is introduced, not into the virtualization of a world, but *in* a virtual world. It involves the reconciliation of the traditional figures of the aesthetic subject like an actor (participation in the work) and spectator (identification with the work). And for all this to be experienced with intensity, the design of the virtual world as the setting for the narration becomes a fundamental piece.

Summarizing, therefore, virtual architects are ke for an aesthetic experience on behalf the subject, the player, in the work, the video game, and that, therefore, it can become as such. It is this way because through their design, they allow the subject to be immersed in the work. The creation of a good scenario allows for true simulation: the player takes the place of the character of the video game and can enter the storyline that occurs in the play. In this way, the storyline of the video game is no longer a mere representation of events like in the theatre, on the one hand, since the subject makes decisions that are answered by the work and determine the course of events. A prefigured story is no longer represented, but an event is developed. On the other hand, and this is the decisive moment, the player is able to effectively feel within the story thanks to a series of simulation regulatory mechanisms, which in a decisive way, have as their author the virtual architect.

At this point we can say synthetically: a video game is the computer realization of a game. For this reason, it is capable of making, not representing, a closed and consistent virtual world in which the actions freely chosen by the player have a coherent response. And the task of building spaces that occurs in it ceases to be, as it had been in traditional arts, that of representing a space, to become that of creating a *space of representation* where the open work is developed.

1.2. Regulatory mechanisms of the immersion: relation between real and imaginary

As it has already been mentioned, when a model is applied to a storyline, or its inverse, a storyline on a model and, above all, when carried out successfully, the so-called immersion occurs by decontextualizing the player's actions in a virtual world. Since its first productions, advances in technology and the expertise of designers have been increasing the complexity of video games and their immersive capabilities. In this section, we will present three key moments of that evolution, by way of three video games that have become classics for *gamers* and their corresponding contributions. In all of them, the enhancements of the game scenario by virtual architects are highlighted.

1. *Metal Gear Solid* (1999).[3] The scenery becomes the *environment*

What interests us in this first case of a video game, which, in its approach could be

[3] Metal Gear Solid, 1999, Konami

considered as a shooter, is that it included subplots that could be classified as infiltration or stealth (Fig. 1). Later these game mechanics have become a genre in them. The protagonist is a secret agent who carries out a series of missions that are nested together to form a plot. And in order to complete them, he must infiltrate and avoid being discovered by the enemy. This circumstance gives way to a more intense connection between the player and the game scenario, in such a way that the experience becomes much more immersive. You must be permanently alert to everything around you; elements that allow you to hide, a place with good views to observe the terrain and the position of the enemies, but also a metallic surface or a puddle that, when stepped on makes a noise, raising the alarm and warning the enemies of your presence. In short, the stage becomes an *environment*.

Figure 1. Screenshot from the game: Metal Gear Solid. Source: (Playstation 1999).

2. *Silent Hill 2* (2001).[4] The scenery gathers presence

The video game Survival horror in which the protagonist receives a letter from his wife asking him to meet her in the city of Silent Hill. He is met with a sinister panorama, and he has to deal with monstrous beings, while he looks for clues, solves puzzles and understands the fatal destiny of the city and also of his late wife. At that moment, the technical difficulty of virtual architects to introduce into the game engine large spaces with great detail was solved in two ways. In interior scenes (Fig. 2), such as a hospital for the mentally ill, the spaces appear compartmentalized, the succession of each one of the spaces acquires the quality of success, and the poor lighting does not allow to glimpse anything at a long distance, since it generates disturbing shadows. In the outer spaces, everything seems wrapped in thick fog. The game's maddening setting is at the service of the psychological horror story it is telling. All this makes the places where the character is located express themselves: not only as a physical environment but also as an emotional one.

Figure 2. Screenshot from the game: Silent Hill 2. Source: (Playstation 2001)

3. Ico (2001).[5] The scene as an additional character

In this three-dimensional platform game, a young man named Ico is taken inside a castle, where he meets another young woman named Yorda and together will try to escape the castle by facing the evil queen and the shadows. For the design of the game, the developers used the technique of *subtracting design*, a kind of minimalism that consists of reducing all the elements to a minimum in order to provide them with greater complexity and importance. In this line, the only setting in which the game takes place, that is, the

[4] Silent Hill 2, Team Silent, 2001, Konami
[5] Ico, Sony, 2001 Computer Entertainment

castle (Fig.3), while imaginary is a realistic environment with a very careful architectural design and recreation. The camera follows the characters on their journey through the castle, changing their focus to highlight certain important parts to be able to advance, or Yorda herself, who does not communicate verbally with Ico, points out certain points that allow us to discover the solution to get out of a room and access another. A simple plot, and reducing the characters to a bare minimum elevates the role of the castle.

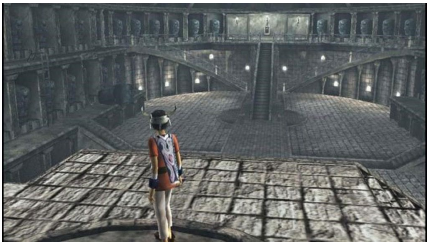

Figure 3. Screenshot from the game: Ico. Source: (Playstation 2001).

2. THE VIRTUAL WORLD AS A BIOPOLITICAL MECHANISM

So far, we have discussed the relationship between the player and the video game, in order to focus on the regulatory mechanisms that allowed immersion and aesthetic experience between them. We have taken the video game artifact to study and in this regard we have seen how it was determined by its designers. In this second part, we will analyze how the video game as a virtual world can determine the player.

It has also been explained that, the video game, in so far as a game, has certain characteristics that define it: a beginning and an end, in other words, an objective; some rules governed by the model and the actions of the characters determined by the player. So, the objective as well as the rules and limits of the decisions are determined by the video game itself. The conditions are presented to the player as given and in such a way that he has to abide by them. This is easy to understand in terms of the specified objective and once reached, ends the game just like the rules, which are programmed in the model. And the actions?

With this in mind, it is worth giving an example for which we will use the three video games previously discussed. The same object, in this case, a box, can vary its meaning depending on the virtual world in which it is presented to the player. Thus, a box in *Metal Gear Solid* may be ammunition or something that if fired will cause an explosion, in *Silent Hill 2* the hiding place of a clue that allows the plot to advance and in Ico, an object that placed in a certain position allows and that from it allows the character to reach a balcony and flee from the shadows. That is, the meaning of the same object is determined in different ways depending on the world in which the player is. Thus, if the player relates to objects as essential parts of the coherent unity of meaning that is the video game, it seems logical that the actions are also determined to some degree from the video game itself. Or, in other words, an external planning intervenes in the player's experience with the video game.

From a biopolitical perspective, if we can understand the player as an object of power within the scope of the virtual world, this would be relatively limited in range. However, we will soon realize the potential that this fact has given the moment we are in. We live in an era of the virtual, we are surrounded by interfaces, mobiles, Tablet, PC ... These interfaces are present in many of facets of our lives: they influence the way we communicate, spend our free time and help us in the workplace. The innocent *Pokémon Go,* brings us face to face with the issue of augmented reality, in which it is not strictly reality that is increased, but its meanings, *big data* and the *Smart city* are a good indication if it. Within this network of meanings, the same body can be understood as one more sign, unfolding in different ways

depending on the social network in which it is shown.

But this virtual alignment to which the subject is exposed: the distance between its real and imaginary conditions, occurs at this period, within the field of the symbolic. Remembering Chaplin's *film Modern Times,* where the subject was overwhelmed by the assembly system in the factory, today, this pressure is subtler. As in the model, the rules do not directly govern the actions of the subject; it is about promoting the conditions for the subject to take certain actions for himself. In other words, in the virtual age, the actions of the subject as an object of power are not directly determined, but properly laid out for the field of the symbolic; the conditions are given to carry out certain actions. This battle, as Abel Gance, and, of course, Walter Benjamin well advanced, takes place in the world of images and redlines the question:

> The language of images is not yet ready, because we are not yet made for them. For now, there is not enough respect, enough regard for what they express.
>
> In the dream in which, in images, the following takes place before each stage, the latter appears linked to elements of prehistory, that is, of a classless society. Society whose experiences, which have their place in the collective unconscious, produce, by intermingling with the new, a utopia, which has left its mark on thousands of configurations of life, from permanent constructions to fleeting fashion.

In effect, this path leads us to examine images in video games due to their symbolic power. The player, where possible, processes the images that are transferred to him and the *ideology* they imply. Thus, video games that propose alternative realities, that invent virtual worlds set in dystopian cities question the player, through images, about their role in an alternative socio-political system. The cognitive processes provoked and the ideological doubts that arise are especially complex given their particular form of interaction. Meanwhile, thanks to immersion, the player is both and "*I*" and an "*Other*"; not with respect to the invented polis, but with respect to his own.

In this sense, there is no doubt about the relevance that virtual architects acquire, as urban planners, and builders of the images that configure alternative realities. The task that follows, analysing three examples of dystopian cities from three video games is quite complex. As the cultural theorist Frederic Jameson explains well, drawing a *cognitive mapping* as an attempt to understand causes and effects in artistic and cultural phenomena, is almost impossible given the complexity and infinity of relationships that exist between all agents. We will therefore focus on showing the images of these imaginary and virtual cities and explaining their implications and the mechanisms used through the aesthetics they present:

1.Persona 5 (2016).[6] The city as a prison

Role-playing game with turn-based combat mechanics that develops its plot in a recreated city of Tokyo (Fig. 4). The city is presented through a chromatic selection with a contact base in which black and white predominate, and red as the protagonist in contrast to the other two colours. It presents an interesting example for the analysis since it focuses on a real city, but through a particular optic it becomes a *dystopian environment*, assimilating it to a kind of prison. The player remains "trapped" in it between different commitments to which he is forced to deal with as a way of socializing the character. On the other hand, the reality of the city is intermingled with another level that is called the *Metaverse* an unfolding of reality, in the form of palaces that symbolize the hidden desires of the characters. In some

[6] Persona 5, 2015, Atlus

way, representing the city as oppressive can be a subversive path, although the flight to a virtual world, within the virtual world of the video game itself in which to fulfil fantasies, can be taken as a way of complying with the status quo. A clear example of alienation: while the reality of the subject is oppressive, the illusion of the realization of his fantasies allows him to escape, while preventing him from facing reality or analysing the causes of the oppression he is going through.

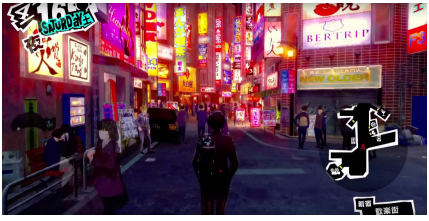

Figure 4. Screenshot from the trailer of the game: Persona 5. Source: (Playstation 2016)

2. *Bloodborne* (2015).[7] The celebration of the *sublime*

Action role-playing video game set in the fictional city of *Yharnam*. The city is full of spectacular buildings that make up a Gothic urban orgy (Fig. 5). This city does not try to imitate or represent, with greater or lesser accuracy, a style or a way of life from some historical period, but rather aims to fascinate the player. It is not an isolated premise; there are many other titles along the same line; from the de-contextualization of Gothic buildings that seem to be taken from old engravings. Here the strategy is to operate on the player through the sublime, to provoke his outburst through majesty, making rational assimilation impossible and reducing his abilities through an avalanche of *self-referential images*. The scene wants to dominate the player; it is, therefore, absolute ideology without content.

Figure 5. Screenshot from the game: Bloodborne. Source: (Playstation 2015)

3. Arkham City (2011).[8] The collapse of a civilization

Action and adventure video game set in the city of the same name. *Arkhan City* is a sort of evolution of the virtual Gotham *City*, for which it offers a panorama of *cyberpunk* aesthetics, in which the remains of a functional old city can be perceived, which have tuned into a kind of sinister theme park (Fig. 6). As in the previous case, it is a very common and widespread aesthetic in many other video games. The panorama consists of a dystopia that shows a corrupted city after a collapse of the capitalist, consumerist and technological civilization. It can be understood as critical speech, cautioning that cyberspace could create a type of totalitarian society connected in unison under one central authority.

CONCLUSION

Virtual architects have played an essential role in the development of the video game, increasingly promoting the total immersion of the player in the virtual world of the video game. On the other hand, their impact on the creation of new *dystopian worlds* is filled with potential since they are capable of influencing the collective imaginary. However, as has already been pointed out, video game as a cultural phenomenon is in its relative infancy, and is still beginning its development. After everything mentioned above, it is worth venturing a future in which video games, together with virtual architects, pay attention to the critical and liberating ways to inhabit spaces: this would be the possibility of resisting an alienation a trend in alienation of a System that wants to close itself off in the pure immanence of what is and in a certain way for no other reason than just that.

BLOCK 8: PARTICIPATION PROCESSES, DIVERSITY AND INCLUSIVENESS

PAPER #8.01

DESIGNING A BETTER WORLD TOGETHER: GLOBAL INTER-UNIVERSITY PARTNERSHIP ADDRESSING UN 2030 SDG

Madlen Simon[a], Shaimaa Hameed Hussein[b], Gregory Weaver[a]
[a] University of Maryland, College Park, Maryland, USA
[b]Al-Nahrain University, Baghdad, Iraq

ABSTRACT

The United Nations' 2030 Agenda for Sustainable Development proclaims, "Children and young women and men are critical agents of change and will find in the new Goals a platform to channel their infinite capacities for activism into the creation of a better world." (United Nations 2015) This paper investigates the potential of a trans-national design studio to empower architecture students to tackle
the UN's Sustainable Development Goals (SDGs). One pedagogical example, Bridging the Gap studio, connects Iraqi and US architecture students through a global inter-university partnership. In this collaborative virtual studio, student teams propose urban redevelopment strategies for parallel sites in one another's capital cities. Alternating between activities of informing, questioning, proposing, critiquing, and iterating based upon growing cultural knowledge, students discover empathy as the foundation of design. In the context of sustainable development, learning in a shared virtual space offers the key benefit of carbon-neutrality, contrasting with the prevailing model of the traveling studio whose
air travel adds to the global carbon footprint. The authors, Iraqi and US architecture studio faculty, together with a PhD student in international education, use the UN agenda as a critical lens for formulating and assessing studio learning outcomes, focusing on the following goals: SDG4. quality education, SDG8. decent work and economic growth, SDG11. sustainable cities and communities,
SDG16. Peace, justice and strong institutions, SDG17.partnerships for the goals. We propose this virtual global learning environment and a set of learning outcomes as a model that can leverage students' shared discipline of architecture to address society's big challenges in a global context, incorporating multiple cultural perspectives, and stressing how everyone and everything are deeply interconnected.

KEYWORDS

International education; design studio; UN 2030 sustainable Ddvelopment goals; virtual classroom; cultural competence.

INTRODUCTION

The United Nations' 2030 Agenda for Sustainable Development proclaims, "Children and young women and men are critical agents of change and will find in the new Goals a platform to channel their infinite capacities for activism into the creation of a better world" (United Nations 2015). The United Nations 2030 Sustainable Development Goals (SDGs) were adopted by all of the UN member states in 2015. The seventeen goals were intended to serve as "a universal call to action to end poverty, protect the planet and improve the lives and prospects of everyone, everywhere" (UN Sustainable Goals website). Architecture students, practicing design thinking to envision the future, can play a changemaker role in implementing this agenda. This paper investigates the potential of a trans-national

virtual design studio to empower architecture students to tackle the SDGs. This model for educational collaboration is well-aligned with the agenda's "pledge to foster inter-cultural understanding, tolerance, mutual respect and an ethic of global citizenship and shared responsibility." The agenda states that, "The spread of information and communications technology and global interconnectedness has great potential to accelerate human progress, to bridge the digital divide and to develop knowledge societies…" The virtual studio became viable in this era of digital connection, with the potential to advance the internationalization of architectural education and promote a sustainable future for the planet.

The paper situates the virtual international studio model within the history of architectural design studio education abroad. It introduces as a case study example Bridging the Gap studio, a virtual classroom connecting Iraqi and US architecture students through a global inter-university partnership. Then the authors, Iraqi and US architecture studio faculty, together with a PhD student in international education,

use the UN agenda as a critical lens for formulating and assessing learning outcomes, focusing on the five goals most relevant to the studio: SDG4. quality education, SDG8. decent work and economic growth, SDG11. sustainable cities and communities, SDG16. Peace, justice and strong institutions,

SDG17. partnerships for the goals.

1. CASE STUDY: VIRTUAL STUDIO CONNECTING STUDENTS ACROSS CULTURE AND GEOGRAPHY

1.1. Internationalization of American architectural studio education

Before the growth of architectural schools in the United States, well-to-do young men and one woman, Julia Morgan, traveled to Paris to study at the Ecole des Beaux-Arts, where they joined ateliers, or studios, and learned alongside their French peers. They absorbed French language, etiquette, and culture along with professional knowledge and expertise. These American students of the Ecole influenced the development of the architecture profession and architectural education in the United States. With the growth of American schools of architecture, it was no longer a necessity to travel abroad in order to gain an post-secondary school architectural education. However, a few American winners of the Paris Prize continued to study at the Ecole des Beaux-Arts each year until 1963 (Schwarzman 1964).

As the discipline of architecture moved into major universities in the latter half of the nineteenth century, the studio was adopted as the locus of design education. American university students were now able to learn to design side by side in the studio setting without the need to travel abroad for this aspect of their

education. The romance of international travel, mainly to Europe, however, was a feature of the culture of architecture dating back to the late sixteenth century when young aristocrats began to venture abroad on the Grand Tour (Sorabella, 2003). The Rotch Traveling Scholarship, founded in 1883, recognized high-achieving architecture students with the opportunity for extended travel abroad. In the second half of the twentieth century, architecture schools began to develop institutionalized study abroad opportunities for students (Costanza 2012). These educational opportunities came to include studio experiences abroad, ranging from brief visits to sites in other countries to semester-long studios in international locations. In recognition of the significance of this development, the Rotch Trustees established the Rotch Traveling Studio Grant in 2002, expanding their funding to focus specifically on studio education that took

Americans abroad. The internationalization of the studio experience runs along a spectrum from minimum engagement to maximum immersion. At the less-engaged end is a group of American students visiting a site abroad with their American faculty. At the highly engaged end is American students studying collaboratively with local students and taught by local faculty in an international setting. With the advent of digital communications technologies, it is possible to realize the benefits of high engagement without physical immersion in an overseas context.

1.2. Blended learning model for international education

The blended learning approach to international education is an emerging pedagogy that engages students with overseas peers without the need for physical travel. This pedagogical model utilizes a variety of digital communications technologies to connect students in coursework both synchronously and asynchronously. Educational modes are considered blended because some learning takes place online and some face-to-face in a traditional classroom setting. When applying blended learning to international education, culture and cultural differences are an important factor to be planned for (Mathur & Oliver 2015). Some benefits of learning globally are job creation, leadership team support in global contexts, and helping students successfully navigate towards their career paths (Hilliard 2015). Blended learning is expanding globally (Vaughn 2007). There is a need for universities to put resources into these programs to prepare students for a global workforce (Morrill, 2007). The blended learning model affords access that students would not otherwise have (Dziuban, Graham, Moskal, Norberg, Sicilia 2018).
Cross-global collaborations and competencies can lead to virtual mobility, increasing educational exchange, and sharing common practices with outside groups (Barajas, 2003). Virtual mobility creates a Community of Inquiry, where physical connection or mobility would otherwise be impossible due to conflict (Garrison, Anderson, Archer, 2000). The blending of asynchronous and synchronous learning environments in the virtual classroom enables students to build diplomacy towards peace in post-conflict environments (Kinder, Fardon, & Yasmeen, 1999).

1.3. Global virtual studio - applying blended learning strategy for internationalization of design education

The global virtual studio is an application of the blended learning strategy. This emerging model for international architectural design education leverages digital communication technology to enable collaborative learning among students in remote locations. There are several potential benefits to this approach. Since learning takes place at students' home institutions, there is no need for air travel, so this model reduces the carbon footprint of international architectural education. Additionally, the no-travel model promotes equity by eliminating cost and accessibility barriers that might otherwise prevent low-income students, students with disabilities, students with family responsibilities, and others who might be unable to travel, from realizing the benefits of international experience in their architectural education.
The concept of blended learning began to be applied to the design studio with the enhancement of design and communications technologies at the very end of the 20th century. The first example the authors have found of a blended learning design studio was a case study of an urban design course that brought together students and faculty in Chicago and Urbana-Champaign (Al-Kodmany et al 1999) - not an international collaboration, but nonetheless a collaboration between somewhat geographically separated groups. The first international design studio collaboration we discovered was a joint

landscape architecture studio linking the University of Washington in the US with Chiba University in Japan (Hou 2003). The earliest application we found of the virtual studio to the architectural curriculum was a 2006 collaboration among design studios at several Turkish universities, an in-country, rather than international collaboration (Tokman 2007). In 2018, a journal article discusses the application of current networking technologies to the architectural design studio and reports on an application of this theory to a virtual architectural design studio in Athens, Greece, another in-country example (Ioannou 2018). The first virtual international architectural design studios that we are aware of are the authors' Bridging the Gap studio, initiated in 2016, connecting an American University, the University of Maryland, with an Iraqi University, Al-Nahrain University in Baghdad (Simon 2017) and a studio linking the University of Los Andes, Columbia with the University of Nottingham, UK, published online in 2016 (Rodriguez, Hudson, Niblock 2018).

1.4. Bridging the gap studio - a case study virtual studio

Bridging the Gap (BTG) studio brings 25 students and two professors from an American university and an Iraqi university together in a collaborative studio designed to develop cross-cultural understanding and the capacity to practice globally. Each studio group serves as information sources, eyes on-the-ground, cultural informants, fact-checkers, and design critics for their counterparts overseas. We share information, hold meetings, and offer critiques through multiple electronic means including WebEx video conferences, Google Drive, Messenger, and a private Facebook group that grows every year to include alumni of the ongoing studio collaboration plus practitioner mentors. The studio collaboration began in 2016, incubated by a multinational architecture firm that has continued to provide advisors and critics to the studio and host our workshops and reviews. They offered internships to two students from each country, further building cross-cultural relationships. The architect mentors serve as role models for global practice, reinforcing for students the real-world application of their studio education. Students tackle parallel sites in the capital cities of each other's countries. Both sites are linear districts focused on commercial streets that are major thoroughfares.

Figure 1. Al-Nahrain University architecture students and faculty

Located in the historically most diverse district of Baghdad, Karrada Dakhil is a lively marketplace night and day with people strolling, shopping, eating, drinking tea, and smoking hookahs. This district experienced the worst sectarian violence in Baghdad with devastating loss of life; it is still rebuilding from the destruction of the bombed mall and mourning the dead. K Street spans different wards of Washington, DC. It is known as a prime location where business and politics comes alive from 9am to 5pm on weekdays but shuts down on evenings and weekends. Both Karrada and K Street would benefit from new visions.

Each team researched their local site and exchanged information with the team abroad. Students next proposed tactical urbanism projects for each other's sites, quick studies to begin to get to know the places and their

Figure 2. University of Maryland students and professional mentors.

problems, raise questions, and elicit rapid responses. Students next launched into a set of research projects on topics including climate, geography, demographics, history, sustainable traditions, urban planning, and architectural history. Based on the new cross- cultural knowledge of people and place, student teams worked on proposals for urban redevelopment. Finally, individual students selected sites within their study districts for architectural design of an urban institution. Students were encouraged to propose urban strategies that would unfold over time, freeing their thinking from the constraints of present-day feasibility to imagine how incremental change could lead to improved futures. The primary constraint was the focus on sustainable design broadly conceived to include social and economic as well as environmental resilience.

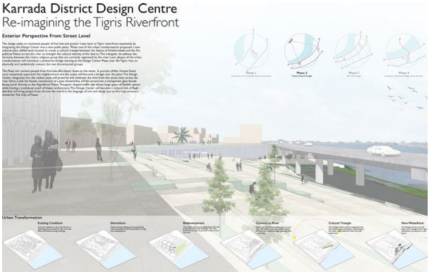

Figure 3. UMD student proposal for Baghdad urban redevelopment. Source (Gijoon Paris Sim 2019)

Figure 4. Al-Nahrain University student proposal for Washington, DC urban redevelopment. Source (Heba Amer Dawood, Aisha Alaa Salih, and Kabas Abdul Hameed Salman)

This international collaboration has been made possible by support by the University of Maryland's Global Classrooms Initiative (GCI) and Gensler, a multi-national design firm. GCI supports the studio with both funding and a faculty learning community dedicated to the internationalization of university education through virtual collaboration. Gensler contributes employee time and expertise and their facilities to support this project that prepares students for the global action that characterizes their practice. The Iraqi- American architects and designers who initiated the studio concept at Gensler have provided access that the US and Iraqi students and faculty would not otherwise have, creating collaboration between countries whose people typically learn about one another through the media rather than in person. Since the Iraq war began in 2003 there have been no international students studying at Iraqi universities (WES 2017), isolating Iraqi students from international contact. The recent political situation has resulted in barriers to Iraqi student and faculty mobility to the United States since President Trump

signed Executive Order 13769 including Iraq in the Travel Ban (Federal Register 2017, NAFSA 2018). Without a virtual learning environment, educational collaboration between Iraq and the United States would be impossible.

2. UN 2030 SDGS AS FRAMEWORK FOR CASE STUDY ANALYSIS

In 2015 the United Nations Member States called for action for people, planet, and prosperity with the 2030 Agenda for Sustainable Development (UN, 2016). This global partnership seeks to reduce inequalities, increase economic grow th, health, and education through 17 Sustainable Development Goals (SDGS) (UN, 2016). The Bridging the Gap Studio (BTG) utilises five of the 17 SDGs in assessing studio learning outcomes. Through our virtual partnership we focus on SDG4 Quality Education, SDG8 Decent Work and Economic Growth, SDG11 Sustainable Cities and Communities, SDG16 Peace, Justice and Strong Institutions, SDG17
Partnership for the Goals. In the following section we will expand on our approach to each of the five relevant SDGs and the learning outcomes from each.

3. DISCUSSION OF LEARNING OUTCOMES

3.1. SDG4: Quality education

> *Goal 4. Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all. 4.7 By 2030, ensure that all learners acquire the knowledge and skills needed to promote sustainable development, including, among others, through education for sustainable development and sustainable lifestyles, human rights, gender equality, promotion of a culture of peace and non-violence, global citizenship and appreciation of cultural diversity and of culture's contribution to sustainable development, 4.7.1 Extent to which (i) global citizenship education and (ii) education for sustainable development, including gender equality and human rights, are mainstreamed at all levels in: (a) national education policies, (b) curricula, (c) teacher education and (d) student assessment, 4.C By 2030, substantially increase the supply of qualified teachers, including through international cooperation for teacher training in developing countries…* (United Nations Sustainable Development Agenda website)

Iraq seeks to achieve the UN 2030 SDGs, especially as their announcement came during the Iraq war against ISIS terrorism, so it was imperative to overcome this gap. In the fourth goal, Iraq seeks to obtain a good education for its youth, so international cooperation was an appropriate method for that, the cooperation of Iraqi universities, including the University of Al-Nahrain with international institutions and universities, provided an important impact. Through BTG, Al-Nahrain University's collaboration with the University of Maryland played a role in the students' acquaintance with technical and scientific methods for solving urban problems including achieving sustainable development. The shared virtual classroom provides students the opportunity to see the capital cities of Iraq and the US through each other's eyes, thereby broadening their education with an international perspective. The first iteration of the studio collaboration evidenced a deficit in the Iraqi students' ability to communicate graphically at a level expected in the global professional community. The faculty collaborated on a grant
proposal that funded a workshop at UMD to elevate the ability of Iraqi faculty from two universities to design curricula and deliver instruction in graphic communication that meets an international standard. By the fourth year of the collaboration, the quality

of the student work had risen to a level that was recognized by the Studio Prize, an international award given by Architect Magazine to six studio courses each year. The effects of the enhanced instruction should grow exponentially as each cohort of graduates produces new faculty to spread their expertise to universities around Iraq.

3.2. Decent work and economic growth

> *United Nations 2030 Sustainable Development Goal 8. Promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all.* (United Nations Sustainable Development Agenda website).

Young Iraqis are protesting in the streets, demanding job opportunities. BTG studio is preparing students to take up the important work of rebuilding Iraqi cities after years of destruction and disinvestment. Through BTG graduates of the master's degree in the Department of Architecture at the University of Al-Nahrain obtained distinguished experiences in working in a global style and the capabilities Qualify them to obtain suitable job opportunities in important institutions in Iraq, including architecture firms and educational institutions. An internship offered by multi-national design firm Gensler enables the top Iraqi and American students to enhance their preparation for professional work by participating in global practice in a US office.

3.3. Sustainable cities and communities

> *United Nations 2030 Sustainable Development Goal 11. Make cities and human settlements inclusive, safe,resilient and sustainable. 11.2 By 2030, provide access to safe, affordable, accessible and sustainable transport systems for all, improving road safety, notably by expanding public transport, with special attention to the needs of those in vulnerable situations, women, children, persons with disabilities and older persons, 11.2.1 Proportion of population that has convenient access to public transport, by sex, age and persons with disabilities, 11.3 By 2030, enhance inclusive and sustainable urbanization and capacity for participatory, integrated and sustainable human settlement planning and management in all countries, 11.4 Strengthen efforts to protect and safeguard the world's cultural and natural heritage, 11.4.1 Total expenditure (public and private) per capita spent on the preservation, protection and conservation of all cultural and natural heritage, by type of heritage (cultural, natural, mixed and World Heritage Centre designation) …, 11.7 By 2030, provide universal access to safe, inclusive and accessible, green and public spaces, in particular for women and children, older persons and persons with disabilities, 11.7.1 Average share of the built-up area of cities that is open space for public use for all, by sex, age and persons with disabilities, 11.A Support positive economic, social and environmental links between urban, peri-urban and rural areas by strengthening national and regional development planning, 11.A.1 Proportion of population living in cities that implement urban and regional development plans integrating population projections and resource needs, by size of city, 11.C Support least developed countries, including through financial and technical assistance, in building sustainable and resilient buildings utilizing local materials.* (United Nations Sustainable Development Agenda website)

The studio projects focus on urban redevelopment strategies, preparing students for professional work addressing the subgoals listed above. In the face of global warming, Americans learn valuable lessons about urban development from Iraqis, whose architecture and rhythms of life have developed in response
to the extreme summer heat. BTG helps enhance the capabilities of Iraqi students

to work toward sustainability, Iraqi students tried with their American colleagues to reflect the knowledge gained through the studio to develop their cities, especially the city of Baghdad, which suffers from neglect and violation of its (urban and cultural) heritage. The students provided through their design solutions for safe and beautiful places to all social and gender groups. American students bring a perspective of diversity, equity, and inclusion to the design of public space. Access for people with disabilities is ingrained in US education, law, and practice. American students bring an ability to envision a peaceful future for Baghdad and to create plans for the buildings and public spaces that will support civic life that can return after the fear of sectarian violence is banished.

During the years that followed the war of 2003 in Iraq, the capital city, Baghdad, has witnessed a rise in crime rate and terrorist attacks (Damluji, 2010). According to the Global terrorism index, Iraq has become one of the top three countries in the world in terms of the number of deaths related to terrorist attacks (Global Terrorism Index, 2018). As a response, a plan for countering terrorism was initiated by the state to mitigate the impact of terrorist hazards in Baghdad (Damluji, 2010). This plan encompassed several strategies and interventions. For instance, concrete barriers and barbed wires were placed around sites of critical importance such as administrative, religious, and educational buildings. To restrain access, streets leading off to these buildings were gated off and controlled by military checkpoints. Consequently, several residential locations were transformed into gated communities (Damluji, 2010; Kilcullen, 2007) and post-war Baghdad has become a city of walls (Chandrasekaran 2007, Basi, Hussein, Abrahem 2019). The events in Iraq encouraged students to provide design solutions that seek to build a healthy and safe society, prevent violence and combat terrorism. Iraqi students bring a fresh vision to the development of Washington, DC, unencumbered by the local devotion to historic styles. By 2030, ensure access for all to adequate, safe and affordable housing and basic services and upgrade slums.

3.4. Peace, justice and strong institutions

> *United Nations 2030 Sustainable Development Goal 16. Promote peaceful and inclusive societies for sustainable development, provide access to justice for all and build effective, accountable and inclusive institutions at all levels.* (United Nations Sustainable Development Agenda website)

BTG studio promotes global peace by building relationships bridging geography and culture through international collaboration. By designing sustainable development plans for each other's cities, Iraqi and American students become invested in the futures of one another's countries. Working together to achieve shared goals, students build relationships that can transform otherness into shared humanity.

3.5. Partnerships for the goals

> *United Nations 2030 Sustainable Development Goal 17. Strengthen the means of implementation and revitalize the Global Partnership for Sustainable Development. Subgoals: 17.3 Mobilize additional financial resources for developing countries from multiple sources. 17.6 Enhance North-South, South-South and triangular regional and international cooperation on and access to science, technology and innovation and enhance knowledge sharing on mutually agreed terms, including through improved coordination among existing mechanisms, in particular at the United Nations level, and through a global technology facilitation mechanism. 17.7 Promote the development, transfer, dissemination and diffusion of environmentally sound technologies to developing countries on*

favourable terms, including on concessional and preferential terms, as mutually agreed. 17.9 Enhance international support for implementing effective and targeted capacitybuilding in developing countries to support national plans to implement all the sustainable development goals, including through North-South, South-South and triangular cooperation. 17.16 Enhance the global partnership for sustainable development, complemented by multi-stakeholder partnerships that mobilize and share knowledge, expertise, technology and financial resources, to support the achievement of the sustainable development goals in all countries, in particular developing countries. 17.17 Encourage and promote effective public, public-private and civil society partnerships, building on the experience and resourcing strategies of partnerships. (United Nations Sustainable Development Agenda website)

The collaborative studio functions as a global partnership focused on sustainable urban development, building architecture students' capacity for collaboration with counterparts in other countries and cultures.It takes young people from cultures recently in conflict and gives them common cause, the need to redevelop the cities and communities of their countries for a sustainable future. Sharing a professional culture and mobilizing for shared goals forms the foundation for partnership. The studio and its related projects leverage funding from multiple US sources, including academia (the University of Maryland's Global Classrooms Initiative), government (IREX and the US Embassy in Baghdad), and industry (Gensler) to enhance opportunities for both Iraqi and US students and faculty. The North-South collaboration of US and Iraq enhances access to innovations in architectural education for the Iraqi partner university. Bridging the Gap studio created a platform for additional projects focused specifically on developing the capacity of faculty at two Iraqi universities to deliver sustainable urban design education and to communicate professional concepts to a world audience. The faculty bring these lessons back to Iraq, educating the architecture students who will graduate to become faculty in universities around the country. Bridging the Gap studio has been building a global partnership over the past five years, with graduates of the program staying connected and contributing their expertise to current students, both inperson and through the growing private BTG Facebook group. When new students enroll in the studio
course, they discover that they are joining this global partnership.

CONCLUSION

Analysis of the case study virtual studio demonstrates that a blended learning approach to design studio education has the potential to expand architectural education's contribution to a sustainable global future. The virtual studio is in itself a sustainable institution, a carbon-neutral alternative to traveling to meet colleagues around the world. The case study studio elevates Iraqi architectural education, preparing Iraqi and US students for contributing to a more sustainable future through employment in the architecture profession. This benefit would extend to other collaborations between countries with disparities in development of educational systems. Intercultural collaboration prepares students for participation in global professional practice. The studio connecting students across culture and geography prepares students to design inclusive, safe, resilient, and sustainable cities through the exchange of information and approaches. A blended learning studio promotes peaceful and inclusive societies and global partnerships for sustainable development by creating a virtual workspace in which our shared profession is a vehicle for cross-cultural collaboration in a post-conflict

situation. When we introduce shared interests and goals for designing a sustainable future, we move away from notions of "us and them" towards the understanding that we are all citizens of the same planet.

The virtual studio grants the students access that they would not otherwise have to colleagues across the world. It leverages shared professional knowledge, expertise, and values to build empathy between students in nations emerging from conflict. The resulting working relationship offers the opportunity to work together towards creative solutions to complex sustainability issues. By building empathy for one another and the problems of their contexts, students come to care about global sustainability issues that may not touch them on their home ground. While the case study studio does not offer solutions to specific

real-world issues, it prepares students for leadership by teaching them how to work together in a global partnership. We propose this virtual global learning environment and a set of learning outcomes as a model that can leverage students' shared discipline of architecture to address society's big challenges in a global context, incorporating multiple cultural perspectives, and stressing how everyone and everything are deeply interconnected.

ACKNOWLEDGEMENTS

The authors gratefully acknowledge funding and other support from IREX, the University of Maryland Global Classrooms Initiative, and the Washington, D.C. office of Gensler.

PAPER #8.02

THE INVENTED OTHER: OF THE "STRANGER-GUEST," NOISE, AND THE CITY

Isben Önen[a]
[a]TU Wien, Department for Architecture Theory and Philosophy of Technics, Vienna, Austria

ABSTRACT

Derrida (2007) sets invention as the introduction of disorder. It is an interruption of the pleasant flow of being and time, or "the breaking of an implicit contract." Like an intellectually distant yet temporally recent utopian thought, invention deforms the existent. This deformation, on the one hand, extends from the existing and, on the other, is the haunting reflection of the non-existent: unseen, but long awaited. Invention is the noise of its time. What, where or who is this noise?

I want to approach the concept of the "stranger-guest" within an extended understanding of the ancient Greek concept *phílos* or friend. Aristotle's attempt to nest himself in his friend was nothing other than an effort to reinvent the self within the other. With Derrida, invention begins "by being susceptible to repetition, exploitation, reinscription." Thus, the "stranger-guest" is always the invented. This inventedness reflects an ambiguous state of being invited yet not being taken into account as a friend. As the unseen-known becomes visible, the archaic Aristotelian friendship is interrupted and noise will echo throughout the ruins of temples. Since the "stranger-guest" arrives with precipitations of centuries-old reflections, transformed attributions to the concept of friend, the host or the *polítis* would never have the time to be prepared. Hence, this encounter generates static. Digging into Lambert's (2017) reading of Benveniste's multifaceted dictionary (1969/2016), I aim to scrutinize the confrontation of the stranger-guest and the host on a spatial basis. What does the space of the *xénos* look like? Or, in other words, how does Russolo's *Intonarumori* in reality resonate?

KEYWORDS

The other; friend; stranger-guest; noise; city; values.

1. BEGINNINGS: AWARENESS

> This. Here this is. Ecco homo. I make history of it: I speak of it. It makes so much noise that it erases everything it says. - Serres

Buchanan (2005) refers to Marc Augé waking up on a mid-summer day in 1984, as described in his *La Traversee du Luxembourg*. Augé's first thoughts within the early hours of the morning lead to the idea that "the everyday, even at its most banal level, is in fact utterly remarkable." With these thoughts, Augé also experiences a moment of uncertainty, which Buchanan links to de Certeau's "shattering (éclatement) and Deleuze and Guattari's "cracking (craquement)." Augé realizes that:

> …anthropology will struggle to locate itself since its object has just disappeared: Since today it no longer seems possible either to delink oneself from the network of relations we call globalisation or find a place out of the way enough not to have been penetrated by it…, it is a mode of inquiry whose object has to all intents and purposes vanished…

He assesses that "[w]e live in a world without others." (Buchanan, 2005) In today's system there is a new type of social space "whose precise purpose is to facilitate a frictionless passage," namely a space failing to become "place": a non-place. However, I argue that

the other does in fact exist, but does so as an invention. And the question is rather, how should one see the present situation where the other-as-invention forces the non-place into a stage of constant confrontation? I suggest that turning to the concepts of *phílos*, or friend, and *xénos*, or stranger-guest (Lambert, 2017), would be valuable. No matter which model of friendship (according to Aristotle's *Nicomachean Ethics*) is dealt with, the concept of friendship foresees an insertion of the self into the other, or with other words, the projection of one's values on to the other. Hence, friendship requires claiming space within each other, dwelling within each other respectively, with no significance of temporality. Who acts first to carve the niche is of no importance, yet how this mutuality unfolds is. The combinatorics in Aristotelian friendships leads to a predictability, but also an ambiguity concerning the human condition: it is impossible to claim anything e.g. virtues in means of purity. Benveniste for his part sheds light on *phílos* and its related concepts; he conveys that the concept "friend" sets sail for distant territories of Indo-European languages accompanied by an apparatus of social and cultural hegemony. For example, departing *phílos*, we arrive at *civis* or the fellow-citizen, and heiwafrauja, hospitality, from Sanskrit and Germanic. The latter, *heiwafrauja*, then becomes traceable in *oikodespotes*, head of the family. In relation to this hierarchical connotation, Benveniste also points out Homer's reference to *phílos* as both friendship and possession. His multi-layered dictionary allows us to look at the concept's afterlife, following its roots in antiquity among a constellation of actors and institutions such as the individual, the family, the city-state, and note how its attributed properties are stretched and forced to change according to temporal and spatial contexts and structures of power.

2. MOBILITY: INTERCHANGING ACTORS

This traceable thread of concepts generates a cloud of plenty and the broadband discussion inevitably penetrates in many areas. I will try to discuss the "brought thing," specifically object and sound, within its relationship to the mobility and memory. Starting with sound, Yavuz (2018) points out to two tendencies in the evaluation of the displaced. First, Yavuz labels the "production of the migrant groups as the misinterpretation of the traditional." In this case awareness of the authentic is obsolete. As the two sub-concepts of stranger-guest (i.e. "stranger" and "guest") augment one another, there is a dichotomy in this point of view. The host, on the one hand is interested in the *strangerness, guestness,* and the *distanceness* of the "other," corresponding to the guest's ephemerality, invisibility, and temporality. This interest is not solely driven by fascination for the ambiguous unknown but at the same time by fear of it. The unknown on the other hand, arrives with authenticity that does not resemble the host. From the moment of its arrival onwards, the guest that only exists as such by a "strangeness" attached to it manifests its power through this authenticity. However, in reality this imported or attached authenticity may only be a mutated one. The personal belongings of the stranger-guest resemble unattended items waiting to be removed by the socio-political mechanisms of the host. Likewise, following its arrival, the stranger-guest is the most powerful and perseverant generator of noise in the harmonious sonorous milieu. It faces two possibilities: being silenced by host-made noise or suppressed and reformed so that it could be interwoven as a part of the milieu. The second tendency set forth by Yavuz is that "the status of being a migrant that belongs to a certain moment, and the physical and mental crossing between two centers [that] are passed to the next generation like a heritage," leading to a vicious circle, which soon itself becomes a tool of suppression:

the migrant status is presented as a method of sustaining the otherness of the stranger-guest. Yavuz also introduces the concept of *niche* and its overarching connotations in ecology, sociology, and economy. This would be important to understand the reflexive starting point of self-legitimization. The space in which the stranger-guest dwells and the place of projection of the self, carving a niche in to the place of the host. If we briefly recall Attali to the complex relationship of the roots and different paths of jazz, for example, with musicians carrying the music with them as they moved on. In this case, jazz music confronted the host and transformed into hybrid forms. The mobility within space or place is confined not only to imagination but also to memory and therefore, cannot operate as in the case of music. This is one of the reasons why the adventure of the stranger-guest is laden with an *in situ* re-erection of memory.

If we continue with the case of the object as "brought thing," Subasi (2011) offers creative input to the discourse by introducing the term invisibility. Her product-based rendering of migration is similar to what Yavuz mentioned in her dissertation: what does the "stranger-guest" bring with? What role can objects of use play in means of mobilizing memory? Invisibility enters the scene as a consequence and undeniable outcome of cosmopolitanism. Whether it comes from the cosmopolitan or suburban, the metropolitan must confront intrusion. In both cases a double-fold confrontation arises: the brought sound or objects belong to the "other," whereas they are only variations of a common essence, nested under the overarching concept of *phílos*. The "other" will always be a pseudo-invented since through all encounters (orientalist but also *occidentalist* intrusions) the host is already accustomed to the other. However, the most powerful impact is experienced when the "other" transforms itself into the "invented" stranger-guest. It is this *inventedness,* recalling Deleuze (2009), that interrupts a pleasant flow of being and time, preparing the grounds for "the breaking of an implicit contract," and like an intellectually distant yet temporally recent utopian thought, deforming the existent. Serres (2017) draws attention to the fact that "the supreme poverty of the system of harmony becomes known to us not only by the nature of things but also by collective establishments." This deformation, on the one hand, is the extension of the existent and, on the other, is a haunting reflection of the non-existent: unseen, but long awaited. An invention is the noise of its time. The impact of an invention lies within the dislocation and relocation of the other: the reduction of distance, which is augmented through the reality that the space of the host has to be shared and the host and stranger-guest claim the same rights. In order to understand how architecture confronts the multi-layered and not fully predictable evolution and alteration within time we only have to look in Akcan's complex analysis of the transformation of Kreuzberg, Berlin. (Akcan, 2018)

Theoretically the host and stranger-guest are on the same level, or equal. As they both exit the front door every day, it is clear that no matter if they have equal powers when claiming space, the claim for place is only reserved for the host. The host's claim, closely linked to an ill-constructed notion of temporality, and significantly with the concept of lateness cannot be taken for granted. It is true that the stranger-guest has no other option than to be late, but time within the concept of friendship is anachronistic and the claimed values are transcendental. The will of existence starts from home or the created niche, a space that is "place" per se. This legitimization is accompanied with a wide range of dislocated objects: furniture, relevant or irrelevant decorations, culinary artifacts, gifts (regardless of usage), musical instruments, and many more.

We arrive at the link between consumption and production, in which consumption mobilizes production to legitimize existence. de Certeau

(2002) names "practices of consumption" as the "ghosts of society." The stranger-guest's quest is to abandon its invisibility and become visible again. "Heterogeneity," set by Subasi as an important input within the world of objects and behavioral issues produces invisibility. For this discussion's premises, the importance of invisibility lies within its relation to different modes of existing: legitimization through which she discusses the invisibility of codification leads to a visual state of non-classifiable, hybrid and simultaneous existences. The basics here would not be other than stimulation through simulating the known. The known or, in a way, "claimed" in an *a priori* sense would become the first tool for the projection of place onto space; the primary surface for this projection would be none other than the shelter, in other words a space with a non-detachable "placeness": home. As this primary space-place is saturated with projections of the habitual, the stranger-guest having claimed its "bastion" steps into the world of the other into the heterotopic world of the invented host.

The city or, as de Certeau names it, the "operational concept," depends on a tripartite structure, which finally is declared as decaying due to shifts of modes of production and a mis-setting of priorities:

> The production of its own space: rational organization must thus repress all the physical, mental and political pollutions that would compromise it
>
> The substitution of a nowhen, or of a synchronic system, for the indeterminable and stubborn resistances offered by traditions, univocal scientific strategies, made possible by the flattening out of all the data in a plane projection, must replace the tactics of users who take advantage of "opportunities" and who, through these trap-events, these lapses in visibility, reproduce the opacities of history everywhere.
>
> Finally, the creation of a universal and anonymous subject which is the city itself: it gradually becomes possible to attribute to it, as to its political model, Hobbes' State, all the functions and predicates that were previously scattered and assigned to many different real subjects—groups, associations, or individuals.

As this concept decays, 'microbe-like, singular and plural practices," manage to outlive the process. These are likened to "noise," as Attali and Serres would have named them, which the metropole "was supposed to administer and suppress," favoring a silence or harmonious music over noise and cacophony. In fact, it is no surprise as the system as a whole is parasitical in which decay only forms one aspect of operational strategies.

3. NOISE

> "Organization, life, and intelligent thought live between order and noise, between disorder and perfect harmony…Noise destroys and horrifies…, [and] it nourishes a new order by injecting a new chance." - Serres

Serres (2007) asks of the country and the city rats enjoying their "royal feast" of leftovers if it was only a noise or also a message, "a bit of information producing panic: an interruption, a corruption, a rupture of information," which frightened them. It is static in a flawless dialogue or, with de Certaud's terminology, a friction in a frictionless system. Noise is an open proposal that is not asked for and, once received, neither the existent nor the other can remain unaltered. In this sense, the French word for noise "bruit," also the title of Attali's book, means "vascular murmur," as the consequence of an obstruction of blood flow at an abnormally high rate. At the same time, in French it corresponds to rumor. Russolo in his *Art of Noise* (1913) claims that the world prior to the nineteenth century was all but silent and muted, and only because of the industrial revolution ne can speak of the reign of noise or *rumori*. Purity resolves into an "amalgam,

[and] assonance into dissonance." The once uncompromising rigidity now reconciles with randomness and porosity. Thus, Russolo sets forth that the world at the beginning of twentieth century is heading towards "noise-sound." Music in the post-industrial age enters the realm of factory, labor, every day, and the world created by them. Just as the concept of friend cannot be separated from that of the stranger-guest, music cannot be detached from noise. Music triggers power and subversion and noise gives birth to both order and disorder. Music, or "any organization of sounds," thus becomes a tool for the "creation or consolidation of a community..." and it could be seen as an "attribute of power in all its forms," linking "power center[s]" to its subjects. (Attali, 1985)

4. RECONCILIATION: VALUES TO DWELL IN

Referring to Serres's assumption that the city and noise create each other respectively, the contemporary urban context cannot be disassociated from the power of the individual. Both feed from the same rear-domain. Every functioning system—ecological, economic, or political—dwells on power struggle and has only one aim: to survive and develop adaptive strategies for sustaining hegemony. The individual starts its claim to existence from the smallest possible denominator. This is the creation of "home," or, in other words, of niches of survival with minimum available sources. This already complicated process gains further complication, ambiguity, and unpredictability as an existing system confronts an "other" from across the border. This "other's" existence was known, its content was discovered, but it had always been kept at the distance of sight. This is the information age's watchtower, the panopticon of recorded vision or, in other words, the server-as-panopticon. In this time of surveillance, the stranger-guest creates the minimum space or niche for survival. This niche is subjective, and this subjectivity has to be sustained. Having entered the city, the stranger-guest now gains an ambiguous dual status comprising properties of the host and stranger but still lacking the power to claim a place in an existing space. Thus, it is destined to be late and it is this lateness that allows the stranger-guest to outlive the decaying conceptual structure. Through this attribution the stranger-guest –with its self-generated noise–is threaded into the symbiotic micro-structure.

Architecture, being located at the crossroads of this plenty has powers that could and should not be underestimated. Architecture has a humanist or posthumanist—whichever the majority is satisfied with—, "civic role" of "satisfying the unspoken wishes of strangers." (Farrell and McNamara, 2020) Pushing the boundaries further in the realm of the ideal rather than in the tangible could lead to the humility of tangible form, being content with a concept of unpolished and imperfect beauty yet not compromising elegance. A sustainable built environment that dwells on values (e.g. democracy, equality), instead on extravagant artifacts; and with an awareness of the different layers of citizenship (Farrell and McNamara), and proposes "overlapping" experiences without need for hierarchies like "stranger-guest," "host," and "lateness," declares a solid validity. An architectonic, theoretical, and ground-up approach has more chances to succeed by forcing itself towards openness and vulnerability and thus becoming a subject of togetherness.

PAPER #8.03

DECONSTRUCTION IN ARCHITECTURE; A HISTORY OF COMPLETE MISUNDERSTANDING

José Manuel Barrera Puigdollers[a]
[a] Universitat Politècnica de València, Valencia, Spain

ABSTRACT

In 2016, David Bestué, the sculptor interested in architecture wrote an article called "The deconstruction in architecture. History of a misunderstanding", regarding the publication by Ginette Michaud and Joana Masó in *Editions of the Difference*, "Les arts de l'espace. Écrits et interventions sur l'architecture". It contains some notes that support the apparent "misunderstandings". However, in different previous writings I have defended the repeated amassing of errors in the reading and interpretation of the theories of Jacques Derrida, which I consider have led not to errors but to complete alienation in his theories on his architectural interpretation. Mistaken in its commitment, interference in its architectural transliteration, lack of rigor on behalf of the institutions, false use of personalism, commercialization, object of worship, simulation in its understanding, etc. Last October 9th, we remember the fifteen years of his death, an appropriate time for an assessment. In a distant architectural context, less polarized and not so significant in these allusions, it seems appropriate to make a critical review, put things in their place and give an honest account to the depth of his work. As he quoted in his farewell to Levinas, the *droiture*, "honesty" or "righteousness," requires us to specify what is "stronger than death."

KEYWORDS

Des-construction; transliteration; constructivism; alienation; simulation.

INTRODUCTION

Few are the direct contacts that the philosopher Jacques Derrida has maintained with the members of architecture, but not with the discipline, from which he always expressed an interest in learning -as he himself indicates- for his resistance (Derrida 1993); *"the resistance to philosophical authority can be produced within a core experience of specializing, of space"*. For the author the resistance to logocentrism has a better chance of appearing in this type of art. In an agitated social and political environment, with an air of emancipation and a certain gentrification of the emerging classes, after 1968 hippie, beat, rebellious and pacifist Marxist-based counterculture arose, with an interest between scholar and transgressor to meet the protagonists of the "criticism of criticism" (Cusset 2005). Initially championed in America by the Yale Quartet - Paul de Man, Harold Bloom, Geoffrey Hartman and J. Hillis Miller. In the period of conceptual coincidence between Eisenman and Derrida –between 1973 and 1984–, the American magazine "Oppositions" became the framework for architectural revision. In it, many intellectual positions were embodied, but especially the silhouettes of the two more powerful lines that emerged at the time and due to their impact on contemporary architecture were outlined; deconstruction and postmodernism. The first one supports the space-time binomial revising it towards temporality and the second one does not support it, but transgresses it until it is nullified. It is surprising that still today there are some that maintain that they are one in the same. And it is in the scope of "Oppositions" where the relationship between Derrida and

the architects is forged, like the refusal of his contributions, forging the negation of the post-metaphysical current.

1. THE APPEARANCE DERRIDA IN THE ARCHITECTURAL CONTEXT

Derrida appears in the panorama of American thought and architecture in the Conference given at the John Hopkins in 1966, called "Structure, sign and play in the discourse of the Human Sciences", where he states -among others- the term *deconstruction*. A term with an extraordinary influence and relevance in architecture from the 80s, due to its ability to contaminate this discipline, for various reasons that were later misrepresented. The body of that germinal Derrida lecture —contrary to the fascination that deconstruction proposes— dealt with the structuralist impossibility of ruling over the ultimate context of meaning; that lateral look —ultimately to the social context— to assure the acceptance of oneself and recognition of the environment. It was also about the inappropriateness of binding certain signifiers with their traditional meanings, as Foucault has already stated in his *heterotopias* or his "archeology of knowledge"; or the impossibility of *centering knowledge* and knowledge derived from the sign (as it was traditionally understood), composed of a meaning and a signifier as a closed and sealed binomial. Also addressed is the open terrain of the referential *game,* —consciously or unconsciously—, derived from the changing context and the psychological state of the subject in constant transformation, which allow differentiated and successive comprehensive, receptive, self-questioning states that open up to other additions.

And for this, Derrida enunciated the terms *dissemination, grafting, aporia, footprint, marks* all of them from the *difference*, a product of the inherent *hiatus* of thinking, or of remembering and the evanescence of the envelope with which present "the here and the now", the memory of concepts; in whose interstices there is room for other things, other memories, other connections, that not only allow contamination by the Other, but even place the other in a position of reference, transforming what we consider to be true or real. These two questions, which in their reiteration allow Derrida to affirm that nothing founded is fixed, there is no origin, no translation, no introduction, no presentation, no strict, closed and unidirectional communication. In short, universals and foundations do not fit, and therefore metaphysics cannot occur naturally in the subject due to its own impossibility, unless it is an imposition (own or foreign) of code, rule or strict external framework, introduced as act of domination or authority. Even against oneself. In short, what Derrida expresses in his lecture goes beyond the term deconstruction; he announced the rules of post-metaphysics and with it the *radical open work* beyond what was formulated by Umberto Eco in 1961, as an open work in progress (Eco 2017), compared to the closed work typical of idealism included in modernity. Another matter is that it be understood in all its terms, or that the architects eager to borrow a way out at the end of modernity, only approached its obvious part. This is what D. Bestué highlights in the text by Ginette Michaud and Joana Masó (2015): "haste and symbolization destroyed the author's memory".

2. THE WOUNDS OF EISENMAN TO DERRIDA

Peter Eisenman emerges in 1968-69 when he submits two model projects in a joint exhibition at the Arthur Drexler in 1967, with two articles (Eisenman 1975) In his articles he testifies what the design process has been throughout history, which he synthesizes as an equation of the "closed project" made up of (Form + Function + Meaning), from which

all the preceding history has been derived. After listening to the Derrida Conference, he will challenge this in his projects and advance in his philosophical studies (from an aspect of positivism). In short, a parallelism to what is said in that conference on the structure of the sign, composed of significance and signifier, which —according to him— are not inevitably linked, nor do they lead to the same according to context, interlocutor, culture, experience or psyche. However, if we question this equation, we enter the void. We question it either because form and function do not go hand in hand as an indissoluble symbolic unit, or because form is free of function and its meaning (coincidence with the prevalence of the signifier against the signified and its autonomy), or because there is no functional restriction that is limited to established forms, or because the meaning does not only depend on these factors, nor is it deduced unidirectional from them. It is then that we find the *abyss* of open work.

Abysmal architecture, as Scholem quotes in relation to Benjamin regarding the language which is inaugurated (Mendoza 2013, 155-176; Benjamin, 1916), is an architecture without limits, without restrictions, without impairment, without prejudice, modesty or complex, except that inescapably it must serve society, it must be livable and used according to the end for which it is intended; undeniable concepts of service, experience and utility which are neither closed, nor constant in time, nor fixed, so that the inherent adaptability of works already determines by itself the sign of its evolution, but also the sign of its statement. And for this reason, this description establishes the basis of the maximum autonomy that architecture can achieve without abandoning its irreducible principles of social service. Therefore, radical open work is a necessary condition of autonomy, although as we shall see it is not a satisfactory condition.

We have seen from the start how Eisenman tried to put Derrida's revisionist theory into practice (especially in its opening), and it was assumed from the beginning as an *attitude of design* that will essentially play and important role in the architect's professional career. In the 1980s, after Eisenman's studies of philosophy, a personal contact was made between the two in 1985 when Derrida was proposing a text on the *Khora* (place) subsequently published in 1993. In this text he addresses the extensive and complex meaning —while "space"— that Plato gives to this term in his work the *Timaeus,* the philosopher offering his reading to the architect, to debate on the very scope of his discipline, —the space—, a debate which carried on for three years. This reflection 'between the two' focused on the revision of the *"metaphysics of presence"*, a matter of concern and interest for Eisenman, or Libeskind, who was then circulating in relation to other concepts; to the "false determinant consciousness", of W. Benjamin, or the installation of images in memory that once presented are repeated; or by pre-constituted languages, a process in which by imitating, reproducing or simulating, the reasons of origin that are founded in it are blurred and therefore automatically transform into simulations of themselves. Eisenman will give shape to such reflections with the publication —on his own— of "Chora L Works", stating that they were made together with Derrida (published late in 1997), although they had not spoken since 1990. Eisenman had offended Derrida; for appropriation and because he did not understand the issue of *presence* as he himself pointed out, understood through Deleuze (2002). Ignasi de Solà-Morales (1995) tells it in an intelligent way and assigns the term *untimely* to architecture, a term taken from Nietzsche. This declaration can be seen in the presentation of Solà-Morales´ text which was reedited in 2004, where he not even once cites Derrida, he justifies his own architecture, as if it were a personal invention.

This link between the two was created with the invitation of Bernard Tschumi (French Swiss architect) to jointly participate in

the Parc de la Villette of Paris competition —of which Tschumi was the director for having won it in 1982—, whose transversal experience motivates both authors as Derrida shows (1988), and thus their relationship and dialogue continues until 1989. Tschumi was 'knowledgeable' of Derrida's theoretical work from his first approach in this project de la Villete, that of the 1986 Tokyo Opera, and others. He was the promoter and curator of the MoMA architecture exhibition, together with Mark Wigley and Philip Johnson, in 1988 on *deconstructivist architecture* (not to be confused with deconstruction) whose impact on the discipline was as relevant as it was false; because they symbolized something untrue. Tschumi had no scruples, knowing the theoretical depth of the Derridian deconstruction, in accepting the imposture of the term "de-constructivist". Manfredo Tafuri criticized these approaches because he did not trust this post-structuralism since he saw it as a bourgeois product without a truly transformative political intention. By then Eisenman had already become the theoretical reference for deconstruction within the field of architecture. In that time of agreement, both convincingly approach deconstruction as "attitude", alluding to previous examples such as Le Corbusier's position regarding tradition and history, Derrida expressing that:

> Those values of habitability and utility are not those who ultimately dominate the work or design. It is also about freeing architecture from certain aesthetic values. In the end, it is not harmony or beauty that control this work. This does not mean that the product must be ugly, but that, ultimately, its goal is not aesthetic.

Herein lies a criticism that his architects "friends" failed to understand: the liberation from the aesthetic yoke (as external imposition of pre-established norms) does not include two inherent aspects; avoiding the public dimension and service to the society of architecture, which many of these architectures show.

So what is the purpose of architecture? Derrida replies that:

> In a certain way, there is no such purpose. There is a game. It is about placing architecture in its specific place, that is, in a space that is not subordinated to values, for example, utilitarian, aesthetic or even metaphysical or religious.[…]. Tschumi and Eisenman try to free architecture from all those goals that are not, in fact, architectural, which does not mean, therefore (and this is the difficult part), that they try to restore a kind of purity of architecture. At the same time, they place the architectural "strictly speaking" with respect to other arts, to other languages: in Tschumi, with what a cinematographic narration can mean; and in Eisenman, there is a constant exchange with the literary text. We continually find a kind of reciprocal provocation between his "so-called architectural" projects and other spaces of invention, let's just say, of creation.

As we can see, Derrida clearly indicates to them the need to dismantle the anthropomorphic values that have adhered to architectural praxis, but in no case do they lead them to its replacement or alteration, which is ultimately what they provide. (This section takes on more chronological interest, when we read Marc Wigley's text on the Russian avant-garde, in the Catalog of the exhibition months before, justifying the reference to constructivism, with a "name" so similar).

Eisenman had developed his personal career from that assertion, of the "open project", according to his perspective. From an approach based on structuralism, such as the axonometric proposals for variations of the elements of their houses, I, II, III... 11th of Palo Alto, 1978- where he not only tests the semantic capacity of alterations and variations introduced, but also -and with it- an open graphic narrative compared to the closed conventional one (Eisenman 1971).

Such a *game-like* attitude seeks not only to influence the receiver, but also to require him to position himself, to participate, as already stated in the epic theater of Tretyakov, Bertolt Brecht, and included in the aesthetic statements by W. Benjamin, as Eisenman himself collected in "A Adolf Loos & Bertolt Brecht" from 1974. To this game strategy that opens up to the significant participation of the receiver, he referred to as *bleaching,* described as distancing, absence of the author subject, unfamiliarity, and inquiry into the alienation of the architectural form to escape the secular gag. Such a process, refers in its succession to fragmentation, the dissolution of the pre-established form of origin, (the cube), the significant dissemination, and the blotting out or blurring of the traditional form where the trinomial form + function + meaning resides. This could contain certain reminiscences of the deconstructive emergence, even if it is to follow an equivalent process of voiding the traditional unity between significance and signifier in sign formation.

His later strategies of inquiry are determined around scaling (mixing scales) and *overlapping* (process of overlapping planes) in proposals such as those of Cannariego in Venice 1978, Verona in 1985, Long Beach 1986, or La Villette in 1987; conceptualized strategies already researched by Tschumi and, who gives theoretical thought in various articles and texts (Barja 2014; Eisenman 1993; 1992; 1988; 1987; 1986; 1985; 1984; 1984; 1983). But outlining some differences with respect to Tschumi leaning towards Derrida; differentiating the result that came from the montage (Benjaminian concept taken from Brecht), with respect to *scaling*, in the first generates superimposition as well as the second superposition. A nuance that marks the difference between the unit and the unitary, the one and the multiple, the same as the traditional –but more complex or flexible–, compared to the pluri-significant and interpretable. And that is summarized in the difference between closed and open project.

A field of research in which he immersed himself in search for a post-metaphysical architecture, from the acceptance of the open work but also from the *negativity of emptiness and lack of it.* This aspect —of the open work— , that here can no longer go unnoticed.

Although Derrida does not mention the open work in any text (but of the *opening of the text*) as such (but Umberto Eco does (2017) in twelve specific references of his own on Derrida), this reference will simplify the reflection of this text, bringing it closer to the design exercise of architects. One of the derivatives of this relationship that we follow and between the two poles of contemporary architecture, the link that connects Identity and Autonomy but that allows their distance, is precisely the distinction and separation between open and closed work. We understand from Benjamin the idea of closed - when everything that must be said is said and everything that must be understood is in sight, therefore, the understanding of the entire work is feasible and it is about knowing how to see, knowing how to recognize, knowing how to identify on behalf of the receiver. That is, to follow and detect everything said there. In the open work these questions are not fixed; they are posed in such a way that, in the normal interaction between the work and the receiving subject, it must contribute part of its experience, culture, memory, that is, it is not complete and is capable of being completed with the other, an action that produces corruption, the spread or the graft that Derrida spoke of, to be understood. Because its spatio-temporal capacity to integrate into sociopolitical-economic, cultural and bond-generating contexts and settings, beyond its generation limit (authorship that Derrida calls signature), is key in the open work. What in literary terms would distinguish Italo Calvino from Umberto Eco; and in architectural terms what distinguishes Libeskind from Eisenman, both from pseudo-deconstruction.

But how does this break-up between Derrida and Eisenman take place, after such a

close relationship and what are the wounds that cause it? Luis Fernández-Galiano (2004a;2004b) talks about their relationship. Derrida replies: "But, furthermore, I cannot hide that, as far as architecture is concerned today, I feel less competent and inspired than ever." In other words, Derrida's disappointment with Eisenman —who is not able to catch sight of Fernández-Galiano— was not to make him understand the scope of the radical opening of the work compared to the closed or half-open one, and Eisenman's relief when moving away from the deconstruction was the calm assumption of identity in the face of autonomy, which he could not achieve. What is also surprising is that Fernández-Galiano in his posthumous article on the philosopher, beyond explaining that 'he knew him personally', points to third-order questions as justification, when relevant was much more evident. Already in April 1990, the philosopher granted an interview to Brunette and Wills, on the subject of "The Arts of Space", where he responds in parallel to the *Assamblages letters* (Derrida 1990; Eisenman 1990), that caused the divide between philosopher and architects to those who posed as followers, not listening to anything. What Derrida basically highlights and that separates him from Eisenman, –his wound– is the fact that the open nature of the project (as text) is *a necessary but not an adequate condition*. It is necessary since it allows the participation of the receiver, the introduction of other signifiers by the receivers who, in such action, become authors and thus change the work, beginning the circularity of the signifier that allows its comfort over time, with time and giving time. But it is not enough if the themes are restricted, therefore thematized or there is a minimum mediation bias of the first author subject; that is, if the signature persists, the "bad identity" acts. And it is at this point that Derrida is frustrated by not making the architect Eisenman see such scope, wrapped in a communicative environment - in which Fernández- Galiano is a participant - that guides architecture towards the star system. Because the work —Derrida will say— "is welcomed, they simply ARRIVE, it does not contain a signature and it does not choose; it's just sheet music. "Eisenman's mistake was to understand that the opening of the work should be oriented towards *nothingness,* towards *emptiness* (which implies for him a *negativity*), subtracting in such cases what the author himself is, his own Jewish condition, and his own teleology. And so Derrida writes to him in a letter in 1990:

> He formulates a discourse on negativity too easily; he talks about the architecture of absence, of the architecture of nothing (like Libeskind). His works are too inclined to speak of emptiness, negativity, and absence, in a sometimes teleological, even Jewish-theological tone. No architecture can be called Jewish… but his is based on a type of Jewish discourse.

And so he synthesizes such a *necessary and sufficient*, pointed out in other texts (Barrera 2019): "If there is a work, it means that the analysis of all circumstances only served to make room in an absolutely indeterminate place (the OTHER to arrive), to something that is at the same time useless, supplementary and irreducible, finally, to those conditions". Because the exaggeration of the autonomy in a creation empty of meaning end up as a narcissistic identity, as he indicates:

> If there is that kind of practice (personal, narcissistic, self-indulgent) then you don't stand a chance. Its future lies precisely in that the practice is transformed, disfigured… subjected to a normalized or identifiable formula… would have been born dead… it has opportunities since it moves and manages to transform itself, so that it is not instantly recognized… and that it appears as something forbibben…

This is the first wound that Eisenman inflicts on Derrida; he is not able to understand the project as a music score, that allows what has resulted from the forbidden, that is just a call, an "arrival"' that welcomes the receiver. In Eisenman's work, Eisenman himself always emerges cryptically hidden. The second wound comes from the temporary dimension present in the previous process and in the *differance;* because the 'arrival' is a postponement. Differance-*différance,* understood as defer and deferral, which requires spacing where time meets. It indicates, "the effect of the signature cannot be reduced to the effect of authorship... the signature exists as long as a given work is not limited to its semantic content". Later clarifying:

> A signature will appear every time an event occurs, every time there is a production of work, whose occurrence is not limited to what can be analyzed semantically. This is its *significance*; it has its place, its non-present existence, that of the work as a print, as permanence (*restance*). That means that one can repeat it, review it, identify it, walk around it... even if it doesn't mean anything, it is there as an addition to all that. And that excess obviously provokes an *endless* speech; and in this consists the critical discourse... the signature is the occurrence of the work itself.

Therefore, contamination or grafting, if possible, arises in the deferral, in time. This is the basis of temporary *turn*, the wait. At the insistence of Eisenman and Libeskind importing other texts to the work (that become the hypertext of borrowed) and Tschumi's search for transgressions with cinema, for wanting to cryptically connect all the contents and underlying the work, thinking that the cause is well hidden, Derrida clarifies that this is not the way, showing you the reception process:

> The confirmatory act that consists of people arriving and deciding that there is something interesting there..., It all starts with the *contresignataire*, the receiver. The origin of the work resides, ultimately, in the recipient... the temporality of the signature is always this perfect future that instinctively politicizes the work, which delivers it to the other, society, the institution, the possibility, ... It is necessary to say "politics" and "institution", and not simply "someone else", ... this takes us from private to public. A work can only be public.

This being the case, the poignant polyphony of multiple dismembered objects under the sign of what is called deconstruction seems misaligned with what Derrida presents. What would be the tone in which the work should be presented?

> The tone, writing in many tones, does not allow me to reduce myself to a single person or moment. The question of tone is not a pragmatic analysis, of determining the meaning, the thesis, the theme, or the theorem of a text... it is knowing who it is for and to produce what effect... suddenly the person changes, the voice changes and everything acquires spatiality, ... because spatial works that should even produce this effect still give the impression of some sort of order.

For this reason, the deferral time is given a condition where it is possible to omit the established order. In this way, he emphasizes that the seed of his proposal is temporary in nature, since once the work has been left to the world, someone, perhaps, will understand it and assign some signifiers that integrate one other, the other, with the Other. And this is not irreconcilable with the beauty that is intended in the work; for those who advocate voluptuous rupture, incomprehensible formal anarchy, because beauty is a *vibration* related to *time*:

> In no case (inside and outside art) can it be separated from the experience of the body; and therefore from the experience of desire...

> a libidinal nature... inseparable from the relationships with the desire of the Other, ... through the voice, through something that has to do with tonal differences... through of the voice as something that intensifies desire to the maximum, precisely because it separates it from the body. There is an effect of *discontinuation*, of *interruption*, (making love in silence or with the voice only); the voice *separates*, ... then it is about what is in the voice that causes desire; it is a *differential vibration* that at the *same time interrupts*. That is what beauty is, the great beyond, a transcendence, which is inaccessible... and therefore I cannot consume it. That defines a work of art, not being able to consume it; beauty is something that arouses my desire by saying precisely, "you will not consume me.

As E. Miralles points out, you cannot consume what lasts over time, because it is restored sequentially in it. For this reason, Zabalbeascoa (2013) calls Architecture of time -that of Miralles- and deepen in time as subject of the project. In this way, autonomy, radically open work, *différance*, the temporary nature that another, my other self, the Other can germinate the work, are the misunderstandings that led Derrida to distance himself from architects, not architecture. None of this architecture is deconstructive, but only a simulation of deconstruction. The theory of arrival, gift and forgiveness is of inexhaustible patience.

3. THE WOUNDS OF MARK WIGLEY AND PHILIP JOHNSON

Curators of the modern architecture exhibition in 1988, under the title 'de-constructivist', a similar but different word from 'deconstruction'. In this paradoxical similarity, transference occurred: such concepts were understood as those early architects and critics said when approaching these ideas (Libeskind, Gehry, Hadid and critics like Stuart Wrede with the same curators). Primarily like destruction, like rupture, explosion, fragmentation, like disassembly, with reference to other things (constructivism). But that was never the basis for Derrida's ideas that appealed to *dismantle* and *evoke*. That exhibition was a way of representing an avant-garde opportunity, absorbing the wake of a philosophical theory that became a motivation to copy. This representation was signaled by the heterogeneous but repetitive selection in disruptive and hatched codes by Philip Johnson and Marc Wigley at the 1988 MoMA exhibition. A collective error in representation without understanding the scope of these nuances. It is possible to overcome modernity without breaking its deliberative course, although it is necessarily incorporating other cultural parameters. Derrida's sustainable and ecological feminist or gender reading, with absolute adaptability in certain proposals, show that the framework of values can be "re-established", without necessarily maintaining the status quo. But this does not justify the impersonation of its name that leads to the denotation of his theory due to the false transferred balance.

But what did its curators want at that architectural meeting? Philip Johnson (Nieto and Sobejano 1987) unabashed stated the following: (1) "architecture is a decorative art". A demonstration that automatically excludes you from the debate that we are following. (2) He refers to architecture as a frame, dressed in glass, in reference to the Toronto-Dominion Center building, as de-constructivist, although its appearance is Miesian (purely metaphysical). This already indicates that the curator was involved in other different things – transforming a booming post-metaphysical current into a metaphysical impersonation; (3) when asked about the difference between the deconstructive philosophical framework and its de-constructivist name, he points to his reference in Russian constructivism, "it is constructivism in its origin"; (4) when asked about what he found interesting he answers with several notes: Aaron Betsky's book,

Violated Perfection and Giovanini's reference in Coop Himmelblau's work to Malevich, about the decomposition of forms, its paradoxical sensuality and imperfection contrary to classical perfection. Such references are a ploy to distract. The apparent similarity or similarity of lines, designs, angulations, "diagonal, structures, ... designing with that freedom is very exciting", it does not belong to the philosophical register we are talking about. The invention of "de-constructivist architecture", symbolized, with historical foundations, inserted in the institutions, presented with godparents, was the construction of a conspiracy against deconstruction. It sought to make metaphysical the current stream of architectural reflection of underlying layer post-metaphysical more widespread. It was a *firewall*.

If we read the contributions about the exhibition "Deconstructivist Architecture" (Johnson and Wigley 1988) within the architecture program Gerald D. Hines architecture program -Interests in MoMA in NY-, we do not find any parallels with the deconstruction. The preamble to Johnson's text speaks of the coming together of "similar approaches." To confirm this, he refers to the photographs in Nevada of a spring shed, by Michael Heizer; for being "disturbing, dislocated, mysterious... the contrast (with the bearing of machinist architecture from 1932), is between perfection and violated perfection". Years later Derrida would not let the opportunity pass him by to contribute from the deconstruction of Heizer's work, "double negative" in "the double session" and "GLAS" that reveals these insignificant approaches. Like his reference to violence as a fold, different from the one confirmed by them (Derrida 1971a, 48; 1997b; 1994; 1997a); "the fold holds the secret, it is a closed book, and folded onto itself, virginity that keeps the secret of its violation".

Wigley's text does clarify; "It is not that they derive from the contemporary philosophical modality called *deconstruction* (forget the "s" that Derrida adds when deriving the term from Heidegger)... they emerge from architecture and exhibit certain deconstructive qualities"; (really none, except the intention to break its anthropomorphic foundations) "because they deal with dismantling" he will say, borrowing the meaning from Derrida, but referring to different things, changing the meaning; "it identifies the symptoms of a repressed impurity, showing its duality between soft conviction and violent torture, so that the form questioned. This is common but in reality it is a simulation. Therefore, the title is a trick: like the one that Derrida himself highlights months after the exposition in the interview we saw. But Wigley returns to pre-revolutionary constructivism such as the Tatlin's Tower Monument to the Third International of 1919 that inaugurates *the radical line*: "with pure forms, conflicting sets were composed", "stability formalizes instability"; "there is no axis, but a nest of axes"; "it was social, but it was based on function"; "the drawings became reliefs, and from them to three-dimensionality"; "the pure forms are trapped in a twisted frame, then penetrated from within and finally dissolved". A textual link that, turned the base into pure ornament by excluding those tensions between its antinomies, transforming its dynamism into stability, losing the strange part of its designs, its sculptural vision, ending up as a stylistic twist. What Wigley does is formalize a working scheme, some design bases, and some patterns, which in Derrida (1997a) dismantles. The exhibition explores the relationship between the instability of the first Russian avant-garde and the stability of the late-modern period. This is a temporary leap that invites parataxis, the accumulation and not the circulation of time, an object of deconstruction. That was the staging of an *assault,* which Mark Wigley tries to take back when he meets Derrida in 1991 at the University of Columbia, motivated by Derrida: "is there a different between architecture and hospitality? A speech repeated at the Round

Table in Madrid in 1997, where he focuses his answer on the talent and in forgiveness.

Why that attack? The text "Delirio y estuco" ("Delirium and stucco") (Fernández 1996) analyzes the socioeconomic structure in relation to the monopolies of power that fosters the emergence of the two postmodern positions; classicism (*stucco*) and abysmal (*delirium*). Solà-Morales in the same publication states that it was the division between the theory of imitation and the theory of invention, after the debate between innovation and necessity, which later concurred with *experience* (Derrida 1993), in the desire. It reproduced the scenario of the "anti-war" bourgeois imposture of 68, as "anti economic power" in the 70s, a scenario of *control and surveillance* is woven in the 80s at the hand of the epigones of those doctrines. In order to distract the restless people, they propose to transform the radical emerging positions into pragmatism, where the new sorcerer recovers the lost center with the appearance of mass culture. Those upheavals generated difficulties and social demands, while the economic structures had lost growth and relevance. It was necessary to regain control by intensifying violence. From the propaganda empty of content, the operation, a "bloodless fascination for the non-existent as something real" was proposed, with the epigones taking on the role of "fifth column of architecture". Once the material, military and economic power is brought together, a priestly aura is installed, taking a quote from Lippman; "when times get out of control, some attack the barricades and others take refuge in convents".

The origin of delirium founded contextualism, metaphor, analogies and typological invention, generating the "epigonism of epigones", explaining the beyond modernity as "*an illusion-allusion*", through disorder, obliqueness, the evasion and elision common to architects faithful to the representative tradition, even if it is a different self-referential representation. But such an origin led to the generation of works of empty or absent of meaning. A question that did not fit into the dynamics of "the late monopolies that demanded an eloquent code for their envelope, that is, to make it possible for these decorations to have the effect of a *moral rectification* in the face of decadence", which these works showed of the previous system. This supported a genuine *formal riot*, leading to "a re-mastering operation of the *managers*, an updated specularity." Where Philip Johnson played the role of sorcerer, a demiurge of symbolic apologetics. Thus an *ideology of consolation* is presented through architectural images, against those that undermined the structure of the mercantile-industrial bourgeoisie. The figurative recovery led to the iconic, speculative recovery, which alternated the production of images by the most redundant methods and means, in the direction of an altering reality. A "happy context" is therefore created, by having the signifiers tied together, where the effectiveness of *surveillance* led to the dialectic of "surplus value", building "the space where to ritualize the exchange ceremonies". Because "everything is made to be sold, without wasting a second", the circulation in magazines fully entering here. Where the subliminal mechanisms that distilled these spaces were aimed at drawing attention accepting therefore the premise of desire. Generating desire represents "a perspective of new life, facing the insufferable of that reified present (eternal present) and the demand for a more acceptable society", which Eisenman or Koolhaas refer to the new human form of the world; the apocalyptic-sublime. The scene turned towards *animus projects* with which to mitigate the stark interests of affluent society. Because the rise of conceptual art was taken advantage of, the generator of new concepts where the work is exhausted in ideation, so that the need mutates from desire to irrepressible desire, or alienating ecstasy. An area of full autonomy in research that excludes theoretical interference of another nature that

challenges the hegemonic powers. Later on, *architecture of meaning* will emerge from here, that which presents virtuality in substitution of the imagined reality, another step forward of the now digital economic power.

CONCLUSION

Why refer to architecture as *de-constructivism,* in a historical moment where the concept *deconstruction* is declared, in whose shadow some authors said they were working on? Its appropriation: its representation taking advantage of the inertia of such a term: "The word deconstruction, like any other, has no more value than that which gives it its register in a chain of possible situations...
"The context", a question that does not concur in this impersonation. Why do architectures and architects obsessed with deconstruction mix with unrelated people who work in the simple search for their personal reference? For masking appropriation under a pile of comparable signs under the bias of equality, similarity, likeness, resemblance, reasonable, etc. Derrida speaks of an attitude that leads to evocation. Why is a constructivist discourse built around a set of architectures, when its reflective underlying layer is metaphysical, about something that wants to be seen knowing that it is post-metaphysical? To impersonate it and build a firewall that blurs its expansion. And this is exactly what happened.

PAPER #8.04

PUBLIC PARTICIPATION AND CITIZEN PARTICIPATION IN CURRENT VALENCIAN URBANISM

Asenet Sosa Espinosa[a], María Emilia Casar Furió[a]
[a]Universitat Politècnica de València, València, Spain

ABSTRACT

To talk about participation in urban planning is to discuss not only its concept, but also its relationship with the models of Democracy, the meanings of Governance and the governance of the territory. From the analysis of the Law of Territorial Planning, and Urbanism and Landscape (LOTUP, 2014) of the Valencian Community, Spain, and its modifications of 2019, two types of participation, public participation and citizen participation are derived. These are different processes and levels of participation in urban planning and planning, since they have different ends, dimensions and participating agents. In addition, the hierarchical position that the Law establishes between them is significant, subordinating the second one to the results of the first one. This separation and hierarchy invites us to reflect on the concepts of Democracy and Governance that are applied in the development of municipal urban planning instruments. Citizen participation remains one of the workhorses.

KEYWORDS

Public participation; citizen participation; democracy; governance; urban planning law; Valencian Community.

PREVIOUS POINTS

Public participation and citizen participation are terms that seem to be used without making a difference between them in the context of urban planning. Can we talk indistinctly of both? Can they be differentiated from political or democratic theory and especially in the dispositions and processes that the laws in urban planning gather?

In its generic sense, participating means *being part of…*, which leads us towards socio-political and legal conceptions of the forms of government, Constitutional and Representative State, where the dimension and sense of participation evolves within the opposite discourse between liberal democracy and participatory democracy, models that respond to different institutional designs .

Following the teachings of Almagro (2016, 179-182), which synthesizes much of socio-political thought from the middle of the s. XX, the force ideas that underpin the reasoning basic of both types of democracy, regarding the participation of citizens, are the following:

• *Representative liberal democracy.* Citizen participation is limited to electoral participation, to the election of its representatives, or is its preferred instrument. This is the only effective political management medium leadership at the complexity and size of societies today, and respect for property, security and natural rights:

a) The otherwise -direct participatory democracy- will overflow the political system because of the continuous social demands that would lead to bankruptcy (the scale).

b) Citizens are unable to understand the technical complexity of decision-making, solution of political problems and take responsibility for the management of public affairs (Almagro 2016, 181).

The citizen is a managed, their role is passive. The relationship between Government, Administration and citizenship is vertical.

• *Participatory democracy.* Understands participation as a right and value that legitimizes democracy, so freedom in democracy is conceived as a space without domination. Popular sovereignty is not transferable. It implies the expansion and strengthening of the channels of "direct and semi- direct participation", as well as civil association, public hearings and forums. Participation must be influential in decision-making processes and their results respected, so citizens are considered active subjects:

a) They have knowledge of the reality that affects them and the ability to decide.

b) Its effectiveness in solving problems may be equal to or greater than that of specialist technicians. Sociologically it leads to increasing public awareness, social cooperation and democratic involvement with institutions and their procedures, as well as reducing the power of the ruling elites on the democratic path. It has three approaches: deliberative, direct and radical. (Almagro 2016, 181-182).

The citizen is an active part. The relationship between Government, Administration and citizenship is horizontal.

Participation, through this last democratic model, takes a new meaning directed towards collective construction of life and the future. In this sense, Villasante (2009, 14)[1] synthesizes the idea in a praxis aimed at "reflecting collectively, building participatively, based on our own reflexivity, to be more operational and transformative".

Both models seem to be combined in the *New Public Management*, based on the *new governance*, a concept developed and analyzed by multiple authors from public and private framework. Public governance can be defined as a process of self-government and self-coordination, with the participation of a varied network of performers: government, public and private companies, civil society organizations and citizens, in which the direction of society is decided, objectives of coexistence are defined —their sense and direction— as well as the way to coordinate and organize to achieve it (Aguilar 2006, 90 and 2010, 30).

This new direction, therefore, forces states to change laws, transform its institutions and make settings in its bureaucratic apparatus. It surpasses governance - the ability to lead linked to a political performer and the yields of its policy - and it gets installed in a process of constant negotiation among all those who make up the network (Vallés and Martí 2015, 426). Cooperation is in its foundations, also "freedom and unlimited flow of information, innovation and agreements based on commitments and mutual understanding (…) means an equitable distribution and redistribution of power and resources" (González, Gascó and Llopis 2012, 32).

It involves incorporating the citizen as the subject of the process of management and decision making on the collective, recovering, in words of Pindado (2008, 25), both the "political character of citizenship" and the "citizen character of politics."

Therefore, we can talk about a new way to manage social conflict and work consensus.

The citizen participation contained in public participation remains in that network of performers.

	Dimension		Relationes	Citizen role
Liberal Democracy	Limited	Electoral	Vertical	Passive
Participatory Democracy	Multiple Multidimensional	Direct Deliberative	Horizontal	Active

1. URBAN PLANNING. GOVERNANCE AND PARTICIPATION

Fundamentals and processes of governance, commented in previous lines, are related to the participatory democracy, which is a new redistribution of power in making decisions that affect the physical and social space, the territory and the city. It introduces a way to abandon the bureaucratic hierarchy, the "technocratic elitism" (Villasante 2017, 169).

To incorporate this new public management of our cities, the new administrative legislation in urban planning fit participation, cooperation and collaboration of civil society as a different bureaucratic model, by overlapping or curling it sometimes in their administrative traditions.

The Aarhus Convention of 1998 and the European Landscape Convention of 2000 about Environment are the starting point of the European framework in relation to Public Participation. The United Nations Economic Commission for Europe assumed in Aarhus (Denmark, 1998), the Convention about access to information, public participation in decision-making and access to justice in environmental matters. In general terms, it's upheld that "participation must be guaranteed in the authorization procedure for certain specific activities

For its side, European Landscape Convention (Florence, 2000), urges the "development of landscape policies at different political-administrative levels, to establish procedures for public participation, to identify and qualify our landscapes (Zoido, 2012, 13).

Subsequently, in transposition of Directives 2003/4 / CE and 2003/35 / CE)[2], European regulations on environmental information and participation, culminates in Spain in Law 27/2006, of July 18, which regulates the rights access to information, public participation and access to justice in environmental matters. Participation in which Spanish Constitution of 1978 advocates must guarantee democratic functioning of society and introduce greater transparency in the management of public affairs.

Thus, article 16 of the 2006 Law promotes "real, complete and effective participation in preparation, modification and review of plans, programs and dispositions, of general nature, related to the environment, by the Administration"; Furthermore, it is fundamentally established that "public has the right to express observations and opinions when all possibilities are open, before decisions are made on the plan, program or disposition" (regulations expressly include citizen participation)

In the Spanish urban area, citizen participation is subsequently included in the Land Law of 2008[3], which in its art. 3.2 c) establishes "The right to information for citizens and entities representing the interests affected by urban planning processes, as well as citizen participation in urban planning and management"; likewise, in its art. 4 by providing for the rights of the citizen and, after pointing to public information (letter e), which indicates the effective participation "in procedures of preparation and approval of any instruments of management of the territory or urban planning and execution and of their environmental evaluation by formulating allegations, observations, proposals, claims and complaints, and obtaining a reasoned response from the Administration, in accordance with the legislation regulating legal regime of said Administration and the procedure in question ". Nowadays, all of this is regulated in Royal Legislative Decree 7/2015, of October 30, which approves the revised text of Land and Urban Rehabilitation Law, art. 5.e), within basic statute of the citizen, and in relation to the citizen's rights.

In summary, transparency, openness and citizen participation are the three

[2] Directives on public access to environmental information and by which Directive 90/313 / EEC, of the Council, and Directive 2003/35 / EC, of the European Parliament and of the Council, of May 26, 2003 is repealed, which establishes measures for participation of public in certain plans and programs related to the environment and which modifies, with regard to public participation and access to justice, Directives 85/337 / CEE and 96/61 / CE, by reference in Fernando Manero, M., "La participación ciudadana en la ordenación del territorio: posibilidades y limitaciones", Geographical Notebooks, 47, 2010-2, pp. 47-71, at p. 57.

[3] By Real Decreto Legislativo 2/2008, de 20 de junio. Texto Refundido de la Ley del Suelo.

axles on which governments and public administrations must design public policies and specify their forms of implementation and evaluation.

The countries of European environment (France, Germany, United Kingdom as well as Spain), coincide in pointing to the binomial citizen participation and administrative efficiency attending to new forms of relationship and involvement that rebound on management; legislative reforms are therefore necessary involving new instruments where participation is more extensive, more relevant in decision-making, and, in addition, it must be aimed at both organized and non-organized citizens (Ganuza, 2004).

To observe the status of citizen participation in urban planning in Spain, we will analyze the Valencian case through the relevant Legislation in urban planning. We refer to *Law 5/2014, of July 25, on Territorial Planning, Urban Planning and Landscape* and its modifications of 2019 (LAW 1/2019, of February 5, of the Generalitat, of modification of Law 5/2014, of July 25, of land management, urban planning and landscape of the Valencian Community).

In this analysis we will try to answer questions like: in the relevant legislation on Valencian urban planning, does a liberal conception of democracy predominate?; What's the position and role of the participants?; Is there a hierarchical separation between the participation of government public entities and the participation of citizens? Does this legislation include consultation of the population and establish a system of binding decision-making?

We will start from a brief reference of the national legal framework, to focus later on the specific reference law.

1.1. Legal framework: transparency and citizen participation

In the Spanish state, through the Constitution, the obligatory nature of the public powers is collected to "promote the conditions so that the freedom and equality of the individual and of the groups in which it is integrated are real and effective; remove obstacles that prevent or hinder its fullness and facilitate participation of all citizens in political, economic, cultural and social life" (art. 9.2).

The right to information and freedom of expression is included in the same constitutional text (art. 20); and, art. 20.1.a, the right "to freely express and disseminate thoughts, ideas and opinions through word, writing or any other means of reproduction". On the other hand, according to article 23.1 of Constitution:

> Citizens have the right to participate in public affairs, directly or through representatives, freely elected in periodic elections by universal suffrage.

More specifically, all people have the right to access public information, in accordance with art. 105.b), regardless of format or support, which is in the hands of any of the subjects included in the scope of Title I of the Act state 19/2013 of 9 December transparency, access to public information and good governance, and that have been prepared or acquired in the exercise of their functions (art. 12 and 13), as well as art. 13.d) of Law 39/2015, of October 1, of the Common Administrative Procedure of Public Administrations.

Likewise, Law 7/1985, of April 2, regulating Bases of Local Regime, comes to consecrate public-citizen participation in a framework of information transparency. With enhanced role of the municipality as "basic entity of the territorial organization of the State", the councils are equated with "immediate channels of citizen participation in public affairs, to institutionalize and manage independently their own interests of the relevant authorities" as well,

> Will provide the most extensive information about their activity and the participation of all citizens in local life. Article 69.1.

Recapitulating, to participation is a democratic principle enshrined in the Spanish Constitution as a fundamental right (art. 23.1) that must be regulated by law (art. 105), establishing forms of participation. As a fundamental right it affects all areas of political action, which includes urban planning, land planning and landscape. The Spanish territorial division, collected in it, recognizes autonomy of the autonomous communities to manage their interests (art. 137), recognizing among its powers the management of the territory, urbanism and housing (art. 148.3rd).
The Autonomous Communities have been legislating in this area for several decades. Currently, the Valencian Community manages and regulates this area through *Law 5/2014, of July 25, on Land Management, Urban Planning and Landscape* (LOTUP) and its 2019 modifications (LAW 1/2019, of 5 of February, of the Generalitat, of modification of Law 5/2014, of July 25, on land use planning, urban planning and landscape of the Valencian Community).

1.2. Legal regime of citizen participation in Valencian regulations

We will start from the consideration of transparency, openness (open access) and citizen participation, such as the three axes on which governments and public administrations are designing public policies and specifying their forms of implementation and evaluation, as thus follows from the preamble of Law 2/2015, of April 2, the Generalitat, of Transparency, Good Governance and Citizen Participation of Comunitat Valenciana. Chapter I, establishes the general principles that should govern actions related to citizen participation, both individually and collectively. The participation instruments are determined in Chapter II and will be indispensable tools for citizen use that will make collaboration between administration and citizens more effective. Participation processes in elaboration of norms, the right to propose normative initiatives and the regime of the Citizen Participation Council are regulated. Under such a postulate, a new model is advocated, which regulates, on the one hand, the obligation to inform and publicize public action, and, on the other hand, the right of access to public information. More specifically, Title V regulates aspects related to citizen participation; consequently, "the active participation of citizens in public affairs" (art. 43., on development and promotion of citizen participation is encouraged —strengthening the associative fabric; citizen involvement; furtherance of communication, meeting and work spaces, etc.—; and, article 44, measures for citizen participation; with reference to the regulatory route).
Translated into the Valencian urban environment, the legal regime of public participation is set up by Law 5/2014, of July 25, on Land Management, Urban Planning and Landscape, of the Valencian Community, which has been modified by Law 1 / 2019, from February 5. This Law advocates transparency that is guaranteed by public participation, from the beginning and in all phases of formulation, approval and monitoring, in the terms required by strategic territorial evaluation.

> All agents with ability to operate in the territory will know from the beginning the environmental and territorial criteria, and the functional requirements that must be taken into account in the development of urban, territorial and sectoral plans (Section I of the Grounds Exhibition of the Law 2014).

In turn, the modifications made by Law 1/2019 insist on the need to guarantee proper citizen participation:

- In the new section 5th in art. 6, in relation to landscape instruments, on the need to submit them to the process of public participation and consultation with the affected administrations.
- In definition of public interested in the processing of the strategic environmental

and territorial evaluation of plans and programs (art. 48. f).

- On regulation of public participation in the processing of planning instruments (art. 49.1b).
- In the new art. 49. bis, in relation to actions prior to the drafting of the planning instrument.
- Equally, public participation plan which refers to the new paragraph 4.c) of the art. 51, which allows "telematic participation from a forum or space enabled where the document is open to citizens and in which contributions are allowed".
- In article 53.1 which includes obligation of the promoter body to submit the strategic environmental and territorial study, as well as the rest of sector documents, to citizen participation: "with people, associations, platforms or groups", which "is have made or provided suggestions in the phases prior to the drafting of plan or program or information in the scope document", etc.

2. ANALYSIS OF THE TREATMENT DISPENSED TO PUBLIC / CITIZEN PARTICIPATION, IN THE VALENCIAN URBAN REGULATION

From all of the above, several fundamental questions can be dealt with from the normative point of view: if the law differentiates public participation and citizen participation, moreover, if it is a separate process clarified in the law in a taxative and/or decisive way.
Attending to the procedure of preparation and processing of the planning, in accordance with the provisions of art. 48 of the Land Planning, Urban Planning and Landscape Law 2014 (LOTUP), the persons and institutions participating in the strategic environmental and territorial evaluation of plans and programs are established, mainly targeting legal persons, public institutions competent in the matter, such as the "promoter body, substantive body, territorial environmental body, as well as the Administrations affected". At this point (phase 0 of beginning) we can affirm that it is attended to the public participation , but far from the citizen participation understood as really involved in the starting point of the elaboration and processing of the planning, with really contributions of what is It will start and what is being done. Citizens would enter to participate, effectively, at a later stage (Phase 1) when there is already a Draft Plan (BP) and a Strategic Initial Document (DIE). The "technocratic elitism" and the hierarchy of specialization, marks the beginning and territorial strategy, so that the results of citizen participation are limited and conditioned since their incorporation into the process. The citizen is an administrator, his role is semi-passive. The relationship between Government, Administration and citizenship remains vertical.
With the modification of the LOTUP in 2019 (of the new article 49bis), in attempt to promote public participation, make citizen participation proactive and more effective, it is noted that before draft plan is prepared, a website of the promoter body will be enabled in order to have a first rapprochement with the public, for 20 days, in relation to a document that briefly indicates problems that are intended to be solved, the objectives of the Plan and the possible alternative solutions (art. 49bis 1.), so that it can serve as a starting point.

> (…) Prior public consultation will have internal administrative effects, preparatory to the drafting of the plan, and will give rise to the obligation to prepare a joint response report to the contributions received. The result of the consultation must be included in the file, indicating the number of participants, number of opinions issued and the response report (Article 49bis, 2., Starting document, preparatory work, before the start phase 0).

For the first time the Valencian legislator makes a public consultation before drawing up the Draft Plan (BP), but without elaboration

of an earlier participated diagnosis, ie, again from a diagnosis and proposals processing tea art, without horizontal and collaborative relational model, supported by the basic principle of Governance. On how active advertising is carried out, the volume and diversity of participants will depend, since it is known that the participation of factual powers stands out through the web. Even so, it constitutes an advance in proactive listening and towards a collaborative model. It implies a strengthening of the direct and semi- direct participation channels and is supposed to influence the decision-making processes and their respected results. The path towards the incorporation of Governance in the new management of public goes with small steps, even with verticality between the technical and institutional proposal and the citizen.

In the same way and with the same order of importance is included in the new art. 48 e) —modification LOTUP 2019— as persons and institutions participating in the "interested public", who for purposes of this law may be a natural or legal person in accordance with the law of the common administrative procedure, Law 39/2015; giving non-profit legal entities entry to the platforms or groups represented, with consolidated grouping, or with specific creation as such for that plan or program in question, with compliance with the requirements that the regulations themselves stipulate in this same article that provides it.

The article 51 comes to collect public participation again through citizen participation in its drafting in 2019, since in the following, Phase 1, "the draft plan or program and the initial document strategy", will take part for pronunciation and contribution:

> (…) To how many people, associations, platforms or groups that have made suggestions or provided suggestions in the previous phase (indicated in article 49bis.1) to the drafting of the plan or program, for a minimum period of 30 business days (article 51.1).

The elaboration of the document of scope of the strategic environmental and territorial study will gather the answers received to the consultations made (...)", in the ordinary procedure (art. 51.2 a); and, also, where appropriate, resolution of strategic environmental and territorial report, in the simplified procedure (art. 51.2 b).

On the other hand, the scope document will contain the public participation plan in which:

	LOTUP 2014	LOTUP 2019	
Previous actions	----	Brief Previous Technical Document	Public Consultation, open. Web

	LOTUP 2014 y LOTUP 2019	
Phase 0. Start	Participants: — Promoter organ — Substantive organ	Result: DIE and BP
Technical control.	Participants: — Environmental Organ	Result: — DIE + BP inadmissibility or — Admisión DIE + BP = goes to Phase 1
Phase 1.	Participants: — Public administrations affected — Citizenship	Result: Scope Document Strategic Environmental and Territorial Evaluation (DA EATE)

Table 2. Public and citizen participation in the beginning of urban planning, LOTUP 2014 and 2019. Source: made from LOTUP 2014 and modification 2019

> (…) The public interested in the plan or program is identified and the modalities or breadth of information and consultation (article 51.4.c) LOTUP 2019

As well as possible ways of participation and the possibilities that these must incorporate:

> (…) Telematic participation from an authorized forum or space where the document is open to citizens and in which contributions are allowed" (article 51.4.c) LOTUP 2019.

CONCLUSION

Relevant regulations regarding transparency and citizen participation, both in Spanish state level and within the framework of the Valencian Community, establish the need for proactive participation of citizens in elaboration of plans and programs. In urban and land planning matters, the Law 5/2014, of 25 July, Ordination of the Territory, Urbanism and Landscape of Valencia, has some openness to this type of participation, still marked by self technocratic elitism of Liberal Democracy, the citizen is an administrator who participates from an already elaborated strategy, decided from the governmental apparatus, his role is semi - passive from the administrative procedure established by said law. The relationship between Government, Administration and citizenship remains vertical in the development and approval of urban plans in the Valencian Community.

The partial modification, which this Law undergoes, with new text in force since 2019, provides a new beginning in participatory process in development of urban plans, opening a process of prior consultations based on a synthetic of what is technically thought of what happens and how it is fixed. Even marked by a certain attitude prone to preferences that depart from a democracy of initiative from citizens, from the people, this modification of the Law can constitute a step forward in strengthening the channels of direct and semi- direct participation, prior to the decision making that affects the community, walking shyly towards a collaborative model of relationship between technical and institutional proposal and citizen. Now we just have to wait for the practical experience of its application.

From the analysis of the 2014 LOTUP and its modification of 2019, two types of participation emerge, from public entities and citizens. These constitute different processes and levels of participation in urban planning and land planning, with differentiated purposes, spaces and times, with nonexistent or little collaborative relationship between them in the conception of the present and the joint construction of the future of the city. Thus, the hierarchical position established by the Law between them is made significant, subjecting the second —the citizen— to the results of the first —highly specialized public entities—. A concept of Liberal Democracy thus begins, against the currents of current Participatory Democracy, very sensitive to the application of the principles of Governance for a new management of the public.

PAPER #8.05

SOCIAL PARTICIPATION THROUGH EXPERIENCES IN PUBLIC SPACES IN THE CITY OF GUADALAJARA, MEXICO

Isamar Anicia Herrera Piñuelas[a], Adolfo Vigil de Insausti[b], Alfred Esteller Agustí[c]
[a]Escuela Superior de Arquitectura, Guadalajara, Mexico
[b]Universitat Politècnica de València, Valencia, Spain
[c]Instituto Tecnológico y de Estudios Superiores de Occidente, Guadalajara, Mexico

ABSTRACT

The public space in Mexico is mostly disused spaces and generating conditions of insecurity and unhealthiest. The generation of methodologies through social participation begins to be key to the reactivation of spaces, also encouraging an experimentation of the place from a community constructivist perspective.
With the exposure and analysis of seven public interventions the objective is to compile a range of possible actuations in public space linked to their results in order to improve social, environmental and economical processes in a city. The methodologies used in the analyzed interventions are based on tactical urbanism whose core is strengthened through citizen participation and feedback, being a collective urban design commitment for emerging cities, in recovery or with critical urban problems.

KEYWORDS

Social participation; public space; collaboration; intervention; community.

INTRODUCTION

Seven interventions in different geographical areas of the city and with different goals for the use of public space allow us to identify differences in social behaviour, find strengths in the methodologies, impact and perception of the activities carried out. Although understanding public space is a complex science since behavioural patterns tend to have many variables in themselves, it is possible to determine interventions that have been able to generate a long-term impact based on methodological contrasts.
The objective of documenting the seven interventions considers establishing a chronology of interventions in the city of Guadalajara, Jalisco, since it is becoming one of the cities in Mexico with most improvement from an urban and citizen perspective. On one hand with investigators who contribute to the analysis of the transformation of the historic center as well as understanding of the historic urban landscape, on the other hand, groups that contribute towards mobility prioritizing collective and pedestrian rights, as well as government instruments such as the Secretariat for Substantive Equality between men and women. women and the Secretary of Planning and Citizen Participation; specifically through a new determined program called "Culture of Peace", all these efforts make up what in the state of Jalisco on the public and private level is gestating in the search to improve the conditions of the state, since the last 5 years it rises and falls in the scales of states with greater violence. Although, it is well analyzed since violence not only occurs in public spaces, it does contribute to a significant percentage of its incidence.

1. DESCRIPTION OF THE CASE STUDIES

The research is mainly located at the down town of Guadalajara, Jalisco in Mexico in

order to facilitate the tools of knowledge of the behaviour of citizens through social participation through experiences, these, catalogued as "activations", that is, experiences that they come to transform the patterns of use of public space. During the period 2015 - 2019, a series of exercises were developed in the public space that are described below, In the first part, a summary is placed to facilitate the location of the names of the interventions with respect to the numbering and topic that each one. After that, each intervention has the information about location and date, context and expected result, this to contextualize the reader regarding the place and specific goal of each intervention.

Summary

1.1. Te regalamos una mascota (We give you a pet)

LOCATION AND DATE: The activation takes place in Guadalajara, Jalisco, in the Mezquitán Country neighbourhood during the first quarter of 2014. The activity is focused on specifically reactivating a small park located on Jaime Nunó street between Guanajuato and Del Istmo, this park selected for having the peculiarity of being located just in front of a kindergarten, Hiawatha
CONTEXT: A colony with approximately 10 small vegetated parks, although not specifically in a situation of degradation if in a state of abandonment by neighbours when not using them regularly.
EXPECTED RESULT: That children and parents can be much more frequent and active users of the park that is right in front of the school they attend. The public space may become a detonator in the beginning associated with the acquired vegetation by potential users of the park, but becoming in the long term an acquired habit for the use of the public space.

1.2. ¿A dónde va chofer? (Where are you going, driver?)

LOCATION AND DATE: During Spring and Summer 2014, the initiative arises for the Guadalajara Metropolitan Area, comprising 8 municipalities: Guadalajara, San Pedro Tlaquepaque, Tonalá, Zapopan, Tlajomulco de Zúñiga, El Salto, Juanacatlán and Ixtlahuacán de los Membrillos, however, due to the activities carried out during the first stage, which are detailed below, the municipality in which the activities were manifested and, therefore, impact, were in the municipalities of Guadalajara and Tlajomulco.
CONTEXT: The Collective Transportation System in Jalisco as in many other states is characterized by being a system held by private concessions, the Mobility Secretariat and the General Directorate of Public Transportation does not operate as a regulatory body, causing dealerships not to be forced to comply with a regulated organization, bringing this an endless number of problems associated with routes, paths and stops, these three aspects sharing the same problem: The lack of information.
EXPECTED RESULT: A collective network for signalling bus stops, which is fed between those who have the information and those who do not, but which, in turn, as the collective knowledge increases, those who did not know the information before can be part of the signalling devices

1.3. Hazte paso (Make your way)

LOCATION AND DATE: On the occasion of the car-free day, a specific campaign takes place

on September 22nd, 2015 in the downtown area of Guadalajara.

CONTEXT: The little or non-existent respect for pedestrians is a problem that concerns many Mexico cities as well as many other countries in the world, however, in Mexico, pedestrian victims of run-over are around the figure of 20 thousand annually (INEGI 2020). Although, fortunately, this quantity is decreasing with the last count of 12,884 abuses, it is still an alarming figure for Mexicans, also because it is a gender problem, with women being the most affected, which also represents a public health problem, already declared by the World Health Organization (WHO 2017).
EXPECTED RESULT: Directly respecting the areas for pedestrians marked in the street, and in the short and medium term promoting greater tolerance for the parties involved in mainly motorized mobility in the city.

1.4. Extra-público (Extra public)

LOCATION AND DATE: Held from September 25 to October 5, 2014 (Extra Public 2014) as a workshop to be held in the building called Kukuruchos, located in the municipality of Zapopan, Av. Adolfo López Mateos Sur 2040, Colonia Chapalita Sur. And later to carrying out an intervention in an ejido land located in San Lucas Evangelista, in the municipality of Tlajomulco de Zúñiga, Jalisco.
CONTEXT: A public space not used and abandoned by the administration, with the potential to be a functional area due to its location right on the side of a soccer field.
EXPECTED RESULT: Create awareness of the importance of active public space, using the minimum resources with maximum impact. (Peña 2014)

1.5. Un día para la ciudad (One day for the city)

LOCATION AND DATE: This activation has already been carried out on 3 occasions by the Urban Orthopaedics Office, the first edition was held on February 7th, 2015.
CONTEXT: This place we call Andador is the area located next to the Pilgrim Park, behind the Alameda shopping center, this space was located in the first Workshop: "Proposals for the city", as a key to start rescuing the Tepatitlan River. (Gomez 2016)
EXPECTED RESULT: Understanding how a poorly perceived place can become a cultural tour for pedestrians. (Gomez 2016)

1.6. Espacios humanos (Human spaces)

LOCATION AND DATE: During the year of 2017, a series of recoveries of public space were carried out in the north-eastern periphery of Guadalajara.
CONTEXT: Public spaces in abandonment generating problems of insecurity, meeting point of gangs and unhealthiness.
EXPECTED RESULT: Reactivation and appropriation of public space, generating a citizen commitment for the care and maintenance of place implementations, with a tendency in the medium and long term to improve the quality of life of neighbours and influence the reduction of violence and public insecurity.

1.7. La esquina (The corner)

LOCATION AND DATE: April 29 and 30, 2016, property located in the Santa Teresita neighbourhood, Guadalajara Jalisco on the corner of Juan Cumplido y Reforma.
CONTEXT: A space, which, although belonging to private use, is ceded by its owner in order to carry out activities that benefit the community, providing safe friendly and dignified public space for the neighbours.
EXPECTED RESULT: Creating a space that in design is better planned to respond to demanded and useful activities for neighbours.

2. METHODOLOGY

The methodology encompasses as a critical analysis of the interventions carried out, is based on the plasticity of the systematization of data particularized for each experience of the public space, in which, citizen participation becomes the axis of observation, diagnosis and synthesis of the implementation in each of them. The methodologies adopted by each intervention are described below as a narration of actions:

2.1. Te regalamos una mascota (We give you a pet)

The activity is carried out by the architecture firm Aion Plan; led by Isamar Herrera and Alfred Esteller based on finding the interaction mainly of children and adjacently, parents who visit the school mentioned above from Monday to Friday. Parents and children are invited through small leaflets with information, which are delivered prior to access to the institute to be part of an activity in the park in which they will be given a pet, this, using a pun on the phrase so that be more attractive and increase the curiosity of the receivers. The exercise has 3 phases:

1st Phase. In a space enabled for a small workshop, the activity starts with the infants showing them a series of photographs of public spaces, one of them with vegetation, thus begins the sensitization process through the opinion of children. Later they are explained that adopting a pet is a responsability, which really refers to adopting a small plant for their care in this activity.

2nd. Phase. It is done in a collaborative way, facilitators, parents and children work to do the sowing of the seeds inside small glasses or boxes of reused sources, showing a brief explanation of the components that are involved in the germination process.

3rd. Phase. There is a direct interaction, again between facilitator, parents and child in which a commitment is made, in order that after their seed has hatched and a couple of leaves have sprouted, they must come back to that park to plant that plant and every day after school, go on to check its status and need of water when it's necessary.

2.2. ¿A dónde va chofer? (Where are you going, driver?)

The architecture office, directed by Alfred Esteller and Isamar Herrera, are the ones leading this activity, which is purely shaped by an informative process of using the tool. The citizen initiative "Where are you going, driver?" is a collective information tool that operates through a Facebook group page (https://www.facebook.com/adondevachofer) with the same name, in which some images are preloaded with the truck routes of the Guadalajara and Tlajomulco area, and a description and videos explaining the activity. The intention of these images is that they are downloaded and trimmed as indicated, in the same image, so that they can be used as stencils, which can be used by any citizen to mark the floor of the area where, by individual or collective knowledge, there is a space in which boarding and stops are made by drivers, despite the absence of a formal or built bus stop.

2.3. Hazte paso (Make your way)

This is a signalling crosswalks intervention, in this case, partly undertaken by Alfred Esteller, Isamar Herrera and his team of collaborators; Brando Soto, Vania Ayala and Juan Carlos Barajas. Carried out during the night-early morning, due to Chapultepec area is a high traffic area during most of the day, in the beamed crossing of Avenida La Paz and Chapultepec, on its west side. The activity considered the participation of more than 100 people, who were assigned to different crossings of the city, with the freedom to propose design and painting methodology.

Prior to the day of the activity, in the eve of worldwide pedestrian's day, the entire "Make your way" movement carried out an awareness campaign through social networks.

2.4. Extra-público (Extra public)

Intervention in an ejido land located in San Lucas Evangelista, in the municipality of Tlajomulco de Zúñiga, Jalisco. Conceived as a self-management initiative, the proposal seeks to reactivate the area by providing it with a public space that fosters social dynamics. The intervention is designed by the Madrid office Zuloarq, Bittertank, from New York and the JAPI Guadalajara office, in this context, Aion Plan; Isamar Herrera and Alfred Esteller, join as collaborators for monitoring project impact through an analysis methodology.
The operation is divided into two phases. The first is a series of meetings where the objects that will intervene in the site will be analysed and resolved. The second will focus on the manufacture of objects in the land of San Lucas (Peña 2014), with the participation of the neighbours.

2.5. Un día para la ciudad (One day for the city)

This is a whole day with different activities with some things in common: they are cultural, open to the public and seek to improve the city. In order to a better understanding they can be divided into 3 blocks:
Cultural exchange = Bazaar of crafts, design, food and art
Teaching of the city = Workshops of Mural, Crops and Body Expression
Public Art = An urban installation and outdoor concert. (Gomez 2016)
In this intervention, collaboration was carried out with Urban Orthopaedics, to perform the energy analysis of an urban intervention carried out in Tepatitlán, Jalisco. In order to be able to obtain energy and cost data that were invested to carry out this intervention and thus be able to know the impact at the environmental and economic level.

2.6. Espacios humanos (Human spaces)

This project is created for the recovery, creation and activation of public spaces through citizen participation and the inclusion of the different actors involved in the development of society (government, private initiative, civil society, etc.) with the advice of a technical and social team to guarantee the quality of the space, optimization of both human and economic resources, as well as the generation of communication platforms and processes of social transformation, for the empowerment and appropriation of communities with respect to these spaces, led by Francisco Javier Vázquez Romero, Bladimir Rodríguez López and Lucy Sarahi Estrada Ledesma as part of Collective 1.618, they generated a program called Human Spaces, in which they developed 22 projects to improve public space, under a methodology designed by themselves taking conceptual consideration of the Desing Thinking methodology. Its design, implementation and monitoring process is described by the creators, as follows:
1. Research of the study area, 2. Selection and study of the application area, 3. Community exploration, 4. Contact with community leaders, 5. Informative neighbourhood meetings, 6. Technical research; (this being based on an exhaustive mapping method through observation in which architects, urban planners, designers, sociologists and psychologists participate) to find patterns of use in time and function, 7 Participatory Diagnostic Workshop, 8. Participatory Design Workshop, 9. Development / validation of the architectural project with the community, 10. Preliminary construction, 11. Participatory construction, 12. Activation workshops, 13. Inauguration, 14. Follow-up. The collaboration by the authors of this article was associated in the selection of the materials to be used as

part of a series of recommendations in the line of sustainability and construction of low environmental impact.

2.7. La esquina (The corner)

In that property, activities related to art and sports were already being carried out, but it was sought to establish a type of furniture that, although in its itinerant quality could lead to more activities, as well as integrating a small ramp for skateboards. Alfred Esteller and Isamar Herrera are involved as workshops for the realization of the participatory design of the space, involving the surrounding community.
The design method of the space is conformed with a participatory process through workshops considers a first introductory stage as a neighbourhood board, subsequent design workshop between the team of architects, sociologists and designers to subsequently submit it to a second neighbourhood board for implementation through resources and collective labour.

3. DISCUSSION

The exposure of results allows a comparative contrast to be made, although the methodological application yields diverse results it is possible to make a critical analysis of the observed patterns. In that sense and looking for the opposite of generalization, the results are explained according to the specific goals sought in each intervention, recalling the main axis of all that lies in citizen participation.

3.1. Te regalamos una mascota (We give you a pet)

Once the school's departure time has arrived, of 50 leaflets delivered for 3 days, only 8 families approach the meeting point (see Fig. 1) to learn a little more about the information provided, and of those 8 only one In the next 30 days he will be following the activity.

Figure 1. Workshop at the park with kids. Source: (Esteller 2014)

3.2. ¿A dónde va, chofer? (Where are you going, driver?)

Through the follow-up in the intervention after approximately 6 months, comments are received from two concessionaires who take action to signal official stops with their route information, one of them physically signs, routes 51 being, 101, 604 and 629, the other does not get to know about its actual implementation.

Figure 2. Stencil signalling. Source: (Esteller 2014)

3.3. Hazte paso (Make your way)

The pedestrian crossings were visible for the next two years or so until the paint was completely erased, during this time, Chapultepec promenade being one of the busiest pedestrian roads; mostly during the weekends, it was easy to hear comments in which reference was made not only to the need to keep the area well signposted for the benefit of pedestrians but also positive comments regarding the design implemented. Unfortunately, this initiative did not continue, although it was the 3rd edition.

Figure 3. Painting crosswalk. Source: (Esteller 2015)

3.4. Extra-público (Extra public)

The analysis in this case was focused on the environmental impact specifically tabulated by the use of means of transport used before and during the intervention, found that the use of the car that although if shared was not carried out at its maximum capacity, which magnifies the amount of Energy and waste generated. In this case, citizen participation had a sectorized impact on those who were in the previous process and who were participants during and after the intervention. Of the 3 elements built during the intervention, 1 of them failed to remain in good condition the next day, this also impacting from the energy perspective of the use of materials.

3.5. Un día para la ciudad (One day for the city)

The activity developed satisfactory results regarding the previous mobility and during the workshop from a more comprehensive perspective that led to the use of collective transport and shared car, also, the use of materials was positively impacted by performing everything digitally during the previous workshops and, during the activities on the site, the implementation of waste management by the main team and the citizens, as well as the low use of disposables when having food by the neighbours, was also notable.

3.6. Espacios humanos (Human spaces)

The exercise under the methodology was applied in all the intervened parks, the use of low impact materials was important from the perspective of low environmental impact, but also economically more affordable and with a greater citizen involvement,

Group	Element	People	Kind	Cuantity	Kwh		Days	
Transport	To kukuruchos	15	Car	5	6	30.00	7	210
	To the lot	12	Car	5	15	75.00	4	300
	About carry materials	3	Car	3	18	54.00	1	54
								564
							Total	270
							Easily saved	97

Table 1. Transportation analysis. Source: (Esteller 2015)

Group	Element	People	Kind	Quantity	Kwh		Days	
Transport	To the lot	7	Car	2	6	12.00	3	36
		15	Bus	1	200/60	3.33	3	9.99
							Total	45.99

Table 2. Transportation analysis. Source: (Esteller 2015)

therefore, neighbours that perhaps by time or effort could not be active hands during the interventions, they were in charge of obtaining low-cost materials that were very feasible for their possibilities. Of the intervened parks in which the Aion Plan team was present, none of them generated rejection or apathy on the part of the communities, on the contrary, the team and citizens themselves sought that in their neighbourhood meetings could clarify issues that could be cause doubts to any neighbour.

Figure 4. Children sowing at park. Source: (Herrera 2015)

3.7. La esquina (The corner)

The intervention was not carried out, as there was no collective involvement by the community, it is believed that the private nature of the lot could generate some uncertainty or distrust in order to be more actively involved.

CONCLUSION

Taking into account that the medullar methodology rests on the axis of social participation as a basis for improving conditions, the difference focuses on improving the use of public space in different areas; In that sense, the seven interventions can be classified in order to understand their impact in 3 types: 1: Improvement of public space conditions as a recreation space: 3.4, 3.5 and 3.7, 2: Restructuring of public space as a recreation space , generation of safety and improvement in environmental quality: 3.1 and 3.6. and 3: Improvement of the citizen experience in mobility: 3.2 and 3.3.

The interventions that gave the monitoring and long-term results and considered that had the greatest impact were 3.2, 3.4, 3.5 and 3.6. Being those that, although belonging to different category of use or goal of public space, developed particular methodologies that achieved to integrate greater amount of citizen participation. Being in the first of them, almost massive, and with the potential to generate a greater lobby of pressure for its implementation and monitoring, concluding that it is the community networks that manage to generate a collective force with the greatest impact.

On the other hand, the ones with the lowest impact, 3.1 and 3.7, since they were in a more sectorized organization, in addition to having a much more specific or limited goal, it is likely that they should have used other types of citizen methodologies for smaller groups and where the follow-up was much more accompanied or hand in hand with these citizen groups.

The intervention 3.3 although as an intervention has not continued, other types of campaigns and team groups that come to advocate for the same reason have emerged from the individuals involved in this project, what is considered as a seed in pedestrian participation in Guadalajara. At the same time, other similar interventions in the state and in the country have appeared, showing the data and the concern is firm, although it remains a public health problem and Mexico one of the countries in the top 10 of death due to run-over, are figures that have been decreasing, as a punctual intervention lasted what the quality of materials and goals of the same allowed but not as a long-term intervention.

With this, we can conclude that the methodologies applied are not marked to the greatest success by the issue that is addressed but by the steps that determine each of them according to the audience to which they are addressed.

PAPER #8.06

THE CITIZEN-ARCHITECT: EVALUATING AN INTERACTIVE GAME FOR COLLABORATIVE URBAN SOLUTIONS AND GREEN INFRASTRUCTURE SUCCESS

Courtney Crosson[a], Sandra Bernal[a]
[a] University of Arizona, Tucson, Arizona

ABSTRACT

This paper uses recent citizen-scientist literature to frame a new 'citizen-architect' model where urban actors claim agency in the design and long-term performance of decentralized infrastructure nodes. Municipalities are increasingly identifying renewable, decentralized sources of energy and water (e.g. rainwater harvesting, photovoltaics) as opportunities to add resilience to their cities. Green Infrastructure (GI) is a growing trend where stormwater is managed by expanding pervious areas of natural vegetation throughout a city. However, current implementations largely rely on untrained citizens adjacent to a GI site to provide the necessary upkeep to ensure design performance. Numerous studies have pointed to long-term maintenance as a problematic unknown for the success of decentralized infrastructure. This paper provides a replicable case study for academia to join with local government to fill this current gap. In the case study, twelve Bachelors of Architecture and Master of Architecture students led by one professor collaborated with Pima County Regional Flood Control to develop an interactive, didactic card game. Through this innovative game, high school and university students are engaged in understanding the design and performance of GI projects recently installed by the City in their communities. The game has students build their own decentralized infrastructure networks with the competitive goal of mitigating the most flooding by accruing the greatest number of high performing sites. This study evaluated the motivation and agency of twenty-five high school and university students to actively implement learning outcomes in their communities through pre and post surveys. The paper concludes that by educating young, citizen-architects about new paradigms of infrastructure, they can advocate for the implementation and performance of decentralized solutions within their community. Young non-architects can be trained as citizen-architects to promote and sustain new designs for decentralized infrastructures in our cities.

KEYWORDS

Citizen-Architect; green infrastructure; decentralized infrastructure; community engagement; community maintenance.

INTRODUCTION

Municipalities are increasingly identifying renewable, decentralized sources of energy and water (e.g. rainwater harvesting, photovoltaics) as opportunities to add resilience to their cities. Green Infrastructure (GI) is a growing urban trend where stormwater is managed by expanding pervious areas of natural vegetation throughout a city. The Environmental Protection Agency defines GI as "an approach to water management that protects, restores, or mimics the natural water cycle and one which is effective, economical, and enhances community safety and quality of life (EPA 2020)." However, current implementations largely rely on untrained citizens adjacent to a GI site to provide the necessary upkeep to ensure design performance. Numerous studies

have pointed to long-term maintenance as a problematic unknown for the success of decentralized infrastructure (Chini et al. 2017). This paper provides a replicable case study for architecture academia to join with local government to fill this current gap within GI by engaging young, citizen-architects throughout the community.

Through an upper-level architecture studio course, twelve Bachelors of Architecture and Masters of Architecture students led by one professor collaborated with Pima County Regional Flood Control District to develop an interactive, didactic card game called Monsoon. Through this innovative game, high school and university students without an architecture background in Tucson, Arizona are trained on the performance of GI projects recently installed by neighborhoods and the City in their communities. The game has students build their own decentralized infrastructure networks with the competitive goal of mitigating the most flooding by accruing the greatest number of high performing sites.

The paper begins with a review of the recent literature on citizen-scientist engagement and GI techniques. Links are made between these literatures and the development of the Monsoon game. Next, methods are outlined. Twenty-five high school and university students were engaged to play Monsoon in two separate sessions. The impact of the experience was evaluated through pre-activity and post-activity surveys. Results from the surveys are discussed in terms of change in student understanding, perceived effectiveness of GI, and agency to actively implement learning outcomes in their communities. The paper concludes that the game was successful in increasing student understanding of GI and perceived agency over flooding through GI in their communities. By presenting innovative communication methods (a game) to educate young, citizen-architects about new paradigms of infrastructure, they can advocate for implementation and performance of GI solutions within their community.

1. LITERATURE REVIEW

1.1. The Growth of Green Infrastructure and the Need for Sustained Maintenance

In the last several decades, the use of Green Infrastructure has increased in cities across the United States as a way to address flooding, reduce combined sewer overflows, and promote secondary benefits like heat island mitigation. This paper employs the EPA definition of GI and refers to stormwater mitigation through the use of vegetation, bioswales, basins of various sizes, permeable pavement, cisterns, and channeling devises (such as culverts or curb cuts) (EPA 2020). The goal of using GI in Tucson is to reduce areas of localized flooding and nonpoint source pollution throughout the city. GI has been shown to be more cost effective than grey stormwater infrastructure (Jaffe 2011) and have multiple benefits beyond flood reduction (Tzoulas et al. 2007). Past literature has shown, however, that citizens adjacent to GI sites do not readily understand these multiple benefits (Barnhill and Smardon 2012). To expand citizen understanding, various outreach programs (e.g. Chicago, Portland, Cleveland) have sought to improve GI education upon implementation and encourage the integration of GI into private property.

Despite recent growing adoption of GI across United States cities, several persistent barriers to GI integration have been identified in the literature: lack of knowledge of what GI is and its benefits, deficient data demonstrating benefits and performance, insufficient technical knowledge and experience, and lack of design standards and best management practices, and the need for maintenance and evaluation components of a GI installation (CWAA 2011; Chini et al. 2017). The Monsoon

game sought to fill in the public perception gaps identified Keeley et al. (2013, p 1103) of "making the connection between unmanaged stormwater and environmental degradation; appreciating the role of the individual citizen or neighborhood-level actions in ameliorating this problem; and becoming familiar with and accepting GI within the community." This paper focuses on the barriers of educating community members on GI, its benefits, and best management practices for maintenance.

2.2. The Need for Citizen-Architects within a Sustainable and Resilient City

The use of citizen science (also called participatory or community-based monitoring) has gain popularity in the last several decades. Literature defines a citizen-scientist as a member of the public who collects and analyzes data relating to the natural world, typically as part of a collaborative project with professional scientists (Roy et al. 2012). Extending from this definition, this paper defines a new citizen-architect as urban actors who claim agency in the design and long-term performance of built solutions in their community, typically as part of a collaborative project with professional architects. When applied to GI, there citizen-architects advocate for and maintain decentralized infrastructure modes in their communities.

Despite the growth of citizen science, literature has consistently raised concerns with the accuracy of data collected (Law et al. 2017). Other studies raise concerns about the lack of evaluation of participant learning outcomes. One recent study found that through pre and post survey analysis that the learning outcomes for citizen-scientists were not being achieved despite the collection of data (Druschke and Seltzer, 2012). These critiques of citizen science hit at the foundational objectives to conduct research while changing the public perception of the value of science. Extending these lessons to the formulation of a citizen architecture, this study sought to evaluate learning outcomes and the change in the participant's agency to impact the environment around them. Citizen architecture can expand the public's knowledge of the built environment around them and increase the perceived value of design.

2. METHOD

2.1. Study Area

The Sonoran Desert City of Tucson, Arizona is the area of study for this paper. Tucson faces two pressing and seemingly opposed challenges: (1) a projected shortage in local potable water supplies in the coming decades and (2) a seasonal excess of damaging floods from heavy monsoon rains. Tucson currently imports over a third of its water from the Colorado River 336 miles away, yet concurrently has the highest yearly extreme storm count across Western US Metropolitan Statistical Areas (MSAs) (Bakkensen and Johnson 2017). These urban water extremes affect citizens directly and disproportionately. Tucson averages $9.5 million in property losses each year from flooding in the city center where stormwater infrastructure was historically not installed, mainly in lower income areas (Bakkensen and Johnson 2017). Tucson has a unique stormwater management history. The majority of the urban center of Tucson does not currently have storm water piping. Streets were designed to carry the heavy rain flows that occur during the winter and monsoon seasons to washes throughout the city. Over time, the city grew and greatly shifted its majority pervious land cover to impervious. This currently results in annual flooding in parts of the city leading to chronic property damage and loss in transportation accessibility. To address these issues, the County and City are working to collaboratively develop and optimize a network of sites that will address current flooding issues and retrofit Tucson with a new, softer, GI.

2.2. The Creation of the Monsoon Game

Twelve Bachelors of Architecture and Master of Architecture students led by one professor worked together during a Fall 2018 upper-level architecture studio to develop an interactive, didactive card game called Monsoon. The twelve students used the sites and prototypical GI interventions they were designing throughout Tucson for their studio course as the starting point for the cards game. The overall flood mitigation numbers computed by the County through base hydrological modeling were used to generate a scoring system that communicated the relative impact of each type of site and each system of prototypical pieces. During the semester, the studio shared three version of the game with the director of the K-12 education organization, Project Wet, and the community outreach director of Pima County Regional Flood Control District to gain critical feedback. The game evolved from a highly quantitative, competitive game to one that was collaborative with mission cards and simplified numbers to signify the relative impact of mitigating flooding at each site.

2.3. The Rules of the Monsoon Game

The Monsoon game (Figure 1)contains: Prototype Cards (68 total, each featuring a component of a flood mitigation system), Mission Cards (36 total, each describing a location in Tucson and a mission statement specific to the site), tokens (40 total, used for marking each site location based on the success of the mission), a map (the base of game, used as reference for mission card locations), and a timer (1 total, sand hourglass used for timing each round). In the game, players collaboratively construct water harvesting systems to mitigate flooding and address other urban challenges (e.g. heat island impact or habitatforurbanwildlife)forrealsitesinTucson. Eachsitetheplayerswinismarkedonamap. Together the winning sites form a network of decentralized infrastructure for an aggregate impact on the city. The rules of the game are as follows:

STARTING THE GAME

1. Thoroughly shuffle the two decks.
2. Deal prototype cards to each player as directed: 2 players/10 cards, 3 players/7 cards, 4 players/5 cards, 5 players/4 cards, 6 players/3 cards

PLAYING THE GAME

3. Start the 30 second timer by flipping it over and begin reading the mission card.
4. Players must work together to find three prototype cards that satisfy the needs of the mission card.
5. Prototype cards must match the mission card in order to be counted.

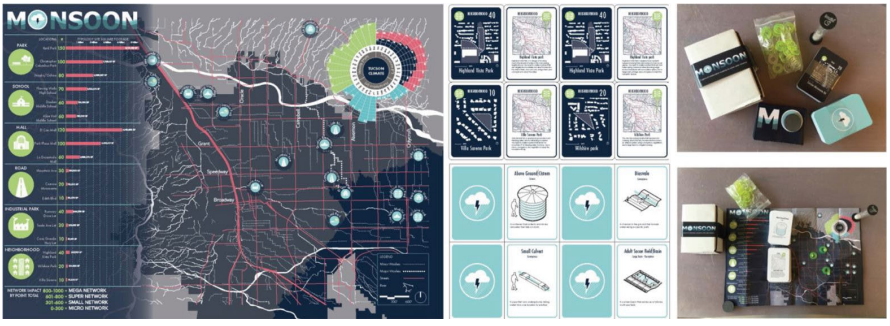

Figure 1. Pieces of the Monsoon Game. Source: (Author 2019 and ARC451b fall studio students 2018)

6. When the timer runs out or the mission card is satisfied, the round is over.
7. If the mission was accomplished in the allotted time, place a green token on the designated site on the map. If the mission was not accomplished, place a white token on the designated site on the map.
8. Replenish used prototype cards to make sure all players maintain 4 cards.
9. All played prototype cards are to be discarded into a used pile to be re-shuffled when the prototype deck is exhausted.
10. Repeat this process until all sites have been played. In the event that another mission card is pulled for an already played site, discard that mission to the bottom of the deck.
WINNING THE GAME
11. Once all mission sites have been played, count the total number of green tokens on the map.
12. Based on the number of green tokens, the title breakdown is as follows: 0-299 Micro Network, 300- 499 Small Network, 500-799 Super Network, 800-1000 Mega Network.

2.4. Engaging Citizen-Architects: High School and University Students

Two groups of students were engaged to play Monsoon: (1) seven freshmen high school students from a local school and (2) eighteen upper-level (non-architecture) university students from University of Arizona. The number in each class was determined by enrollment and student attendance on the day of the scheduled activity and survey. The high school students were engaged through their art class that was learning about urban development and sustainability. The Monsoon game was used by the teacher to teach students about water harvesting concepts and the potential impact they, as citizens, can have on the local landscape and water conservation goals. The university students had limited exposure to architecture, engineering, or design coursework. The Monsoon game was played in the middle of the semester in a general studies course, after students had learned general concepts about urban sustainability. The students had not yet learned about water management, conservation, or GI. For both student groups, the Monsoon game was their first introduction through coursework to GI concepts.

2.5. Evaluating the Impact of Monsoon: Pre-Activity and Post-Activity Surveys

To evaluate the impact of playing Monsoon, all students were given a pre-activity and post-activity survey. The surveys were administered through an online survey interface run through the Qualtrics software. This software anonymized the responses from the participants and created a uniform survey experience. Students took the survey in the classroom either with their smartphone or laptop computer. The pre- activity survey had nine questions and established the student's awareness and locations of a flooding problem in Tucson, understanding of the term GI and the many components of GI (e.g. basin, curb cut, bioswale, culvert, etc.), co-benefits of GI, perceived effectiveness of GI, and total agency as a citizen to make an impact in reducing flooding. The post-activity survey had eleven questions. These eleven questions repeated the nine questions from the pre-activity survey and introduced two new question asking the student to rate the overall impact that Monsoon had on their perceived ability to reduce flooding.

3. RESULTS

Results from the pre and post survey were analyzed to determine the impact that playing the Monsoon game had on the high school and university students (the potential citizen-architects). Survey comparison sought to assess the students' change in understanding, change in perception of the effectiveness of

GI, and change in perceived personal agency to impact their built environment as citizen-architects.

3.1. Understanding

Overall, students showed a marked increase in their awareness that Tucson had flooding issues, understanding of the term GI, and knowledge of the component pieces of a GI design after playing Monsoon (Figure 2 and Table 1). Most significant was the change in student understanding of the term GI and the components of a GI design. Although many students claimed to "know a little bit" about GI before playing Monsoon, after playing the game the 72% reported to be "somewhat knowledgeable" to "very knowledgeable" (as compared to 44% in the pre-activity survey). The number of responses to the prompt "please select the terms on which you have knowledge" significantly increased from the pre- activity survey, from 148 to 226 responses.

The concepts that were significantly better or newly understood by the participates were: Round about basin that went from 3 to 8, edible vegetation from 14 to 20, site inlet berm from 1 to 7, street berm from 4 to 10, micro basin from 5 to 15 and large basin from 5 to 17. However, all the concepts increased for at least one participant.

3.2. Perceived Effectiveness of Green Infrastructure

Students showed a marked change in their perception of the ability of GI to help address flooding problems in Tucson after playing Monsoon. Student selection of "can make a big difference" and "can solve all flooding in the city" shifted from 52% to 84% in the post-activity survey (Figure 3). These results show that the game may even contribute to an exaggerated understanding of the capacity of GI to influence flooding issues as GI is not capable of completely addressing very large

volumes of flooding. The number of responses on the question "which community urban issue can GI impact in addition to flooding?" increased from 111 in the pre-activity survey to 128 in the post-activity (Figure 3). Although this participation is a marked increase, students indicated a general awareness of the ability of GI to have multiple benefits for a community before playing the game.

3.3. Perceived Agency

Finally, students showed a marked change in their own perceived agency after playing Monsoon. Selection of "can make a difference" and "can make a big difference" shifted from 32% in the pre-activity survey to 48% in the post-activity survey (Figure 4). On the question (only on the post-activity survey) that directly asked students to rate the impact Monsoon had on their change in perceived agency, 88% reported that it some type of "difference" (Figure 4).

4. DISCUSSION

4.1. Understanding Green Infrastructure: Educating the Citizen-Architect

The Monsoon game was effective at changing the level of understanding by students of GI, its components, and its effectiveness at addressing flooding and providing other co-benefits. There was a surprising level of prior comprehension of GI in the pre-activity survey. Similar to Baptiste et al. (2015), most citizens

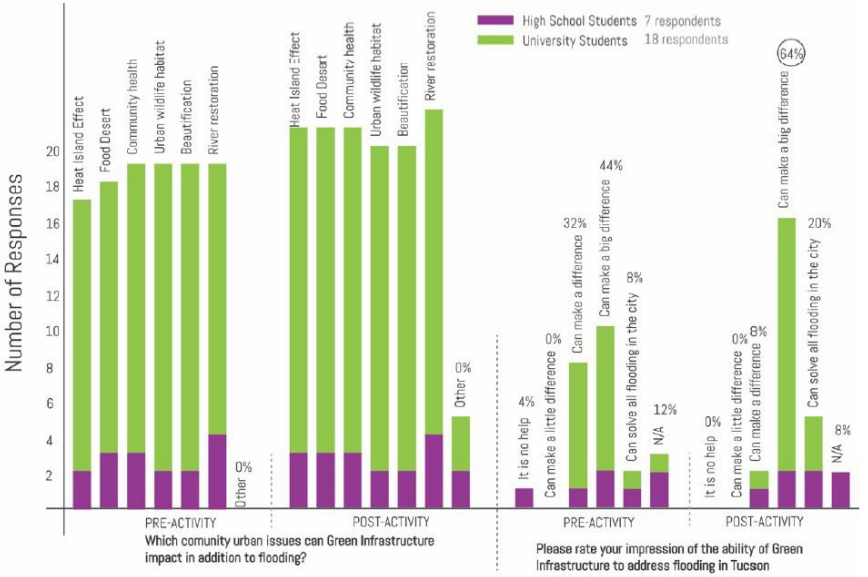

Figure 3. Responses on Perceived Effectiveness of Green Infrastructure. Source: (Author 2020)

had previously heard of the term. Thus, the challenge of the Monsoon game (and other future citizen-architect engagements) is to fill in the public perception gaps identified in the GI literature. Keeley et al. (2013, p 1103) underline a gap identified by their research on GI outreach of "making the connection between unmanaged stormwater and environmental degradation; appreciating the role of the individual citizen or neighborhood-level actions in ameliorating this problem; and becoming familiar with and accepting GI within the community." Among the university students, the substantial change in understanding of the components and functioning of a GI system was a promising result where students went beyond basic understanding to acquire a greater mastery of GI system components to be in a better place to plan, design, and maintain such systems. Finally, the game also supported student comprehension of the effectiveness of GI installations. This marked change in perceived effectiveness (from 52% in pre-activity to 84% in post-activity survey) is critical to bridging the gap between knowledge of GI and motivation to advocate for and maintain installations within a community.

4.2. Instilling Agency: The Responsibility of Professional and Academic Architecture to Train Citizen-Architects

Overall, 88% of the students responded that the Monsoon Game made some difference in their sense of agency to reduce flooding in their community. Professional and academic architects are called upon to broaden architecture and include community members in sustaining the long term performance of realized designs. GI installations are challenged by lack of design standards and best management practices for maintenance (CWAA 2011). Citizen-architects can help

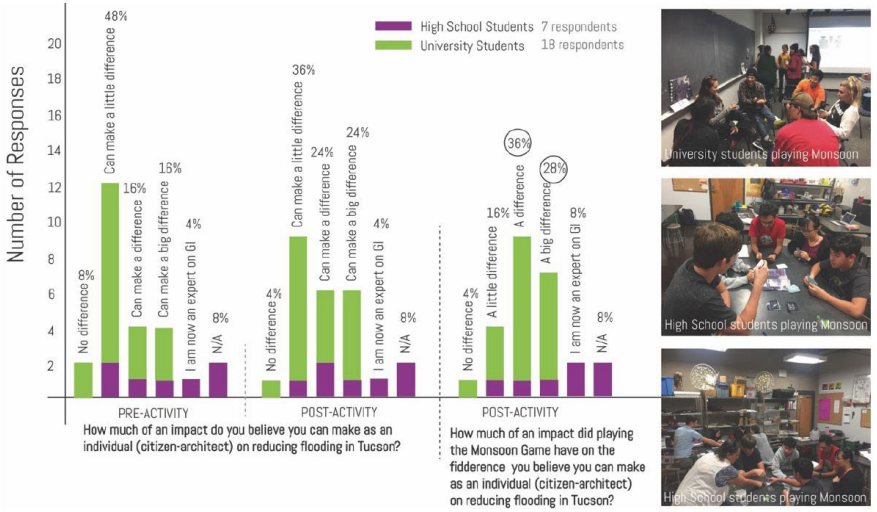

Figure 4. Perceived Agency. Source: (Author 2020)

the municipality maintain GI installations in their community to sustained designed performance and create more tailored and specific standards through this experience. Further, citizen-architects can help address the challenge of dispersed infrastructure. As they are the ones regularly seeing the installations, they can provide the municipality with important feedback and monitoring.

The Monsoon Game can be improved in several ways. As a tool the game depends of a strategic plan for educating throughout communities where GI has been recently installed. The students included in this study were helpful for understanding the effectiveness of the game, but dissemination of the game through a holistic community education strategy needs to be tested. Further, the success of this educational strategy can also be assessed through longitudinal observations of the GI installations in the communities with trained citizen-architects. Continuous education and training every several years is needed to ensure that new community members are provided information and formerly trained members retain knowledge and agency.

CONCLUSION

The purpose of this study was to engage high school and university students without an architecture background in the conceptualization and maintenance of decentralized GI systems. A game called Monsoon was designed and used for the engagement of these young citizens. The strategy followed a citizen-science paradigm where non-scientists are engaged in science-based goals. Similarly, the game sought to connect non-architects with urban design and sustainability objectives.

Results show that the game was successful at increasing student understanding of the purpose of GI, the system components, the target performance, and expanding perceived agency over flooding issues in

their communities. The paper concludes that the Monsoon game can educate young, citizen-architects about new paradigms of infrastructure to advocate for the implementation and performance of decentralized solutions within their community. Young citizen-architects can be trained and empowered by professional and academic architects to promote and sustain new designs for decentralized infrastructures in their comunities.

PAPER #8.07

SPACES OF DIFFERENCE AND ASSOCIATION: ISLAMIST POLITICS AND URBAN ENCOUNTERS AMONG HETERODOX MINORITIES IN TURKEY

Bülent Batuman[a]
[a] Bilkent University, Ankara, Turkey

ABSTRACT

Alevis –a large religious minority of 10-15 million in Turkey– have historically suffered marginalization due to the state's strict endorsement of Sunni Islam. The Alevi demands have become vocal since the 1990s in what has been called Alevi renaissance: the Alevis insist on their difference from Sunni Islam and demand the recognition of their rituals and practices, yet the Turkish state persists that Alevism is a branch of Islam. Within this perspective, the mosque is the sole space of worship in Islam, and Alevi shrines (*cemevi*) cannot officially be accepted as temples.

The last two decades under the Islamist Justice and Development Party (AKP) led to two significant phenomena which made Alevism a challenge to the Turkish establishment. The first is the expanding role played by Sunni Islam in the definition of the national identity. Alevis increasingly feel that they are denied recognition and forced to abide by Sunni practices. The second phenomenon is the gradual urbanization of Alevism due to rural-to-urban migration. These two dynamics brought about an unforeseen outcome: the urban environment became the site of encounter for various strands of Alevis facing the growing dominance of Islamism.

This paper discusses the predicaments of this encounter through the case of Adana in southern Turkey. Being a major industrial city and the center of an agricultural hinterland, it has received migrant (Turkish and Kurdish) Alevis from Eastern Anatolia; it has also been home to nomadic Alevi tribes of the Taurus Mountains and the local Arab Alawites. All these groups call themselves Alevi and the venues built by their NGOs facilitate interaction among them. I will analyze this new phenomenon through a number of recently built buildings and the architectural dialogue they display through spatial and iconographic analyses of the buildings and the interviews conducted with architects and NGO representatives.

KEYWORDS

Alevism; islamism; heterodox Islam; *cemevi.*

INTRODUCTION

The relationship between Islamism and the built environment has been under scholarly scrutiny for the past few years due to the increasing political influence of Islam (AlSayyad and Massoumi 2010, Desplat and Schulz 2012, Deeb and Harb 2013, Batuman 2018). While politicization of Islam (and religions in general) is considered in relation to secularism (as a normative condition of non-religiosity), it is also curious to consider the political responses of minority faith groups. In this respect, this paper focuses on the politicization of heterodox Islamic groups who are threatened by the rise of Islamism in Turkey. The case in point here is the Alevis –a large religious minority of 10-15 million. The last two decades under the Islamist Justice and Development Party (AKP) led to two significant phenomena which made Alevism a challenge to the Turkish establishment. The

first is the increasing role played by Sunni Islam in the definition of Turkish nationalism and the national identity. Alevis increasingly feel that they are denied recognition and forced to abide by Sunni practices. The second phenomenon is the gradual urbanization of Alevism due to rural-to-urban migration. This process has brought about an unforeseen outcome: the urban environment became the site of encounter for various strands of Alevism cutting across ethnic divisions in Turkey. Particularly the increasing influence of Islamism is forcing the Alevis to reconsider their identities with respect to the changing definition of what constitutes the "national."

I will discuss the predicaments of this encounter through the case of Adana in southern Turkey. Being a major industrial city and the center of an agricultural hinterland, Adana has received migrant (Turkish) Alevis from Eastern Anatolia, Kurdish Alevis from the same region and shelters nomadic Alevi tribes of the Taurus Mountains (called Tahtacı) and the local Arab Alawites (Nusayri). All these groups call themselves Alevi and the increasing number of venues built by their NGOs challenge the dichotomy of Islamism versus secularism. I will analyze this new phenomenon through a number of recently built buildings and the architectural dialogue among them, after discussing Islamist attempts at controlling the production of Alevi spaces. My analysis is based on fieldwork conducted in late 2019 which included site visits to the buildings under discussion as well as interviews with their architects and the representatives of Alevi NGOs.[1]

1. ALEVISM: A BRİEF HISTORY

Alevism is the second largest faith after Sunni Islam in Turkey. It combines elements from Shiism and Sufism as well as local rituals and traditions in Eastern Anatolia (Dressler 2013). The Alevi ritual is called "*cem*" and their shrines are called *cemevi* (house of *cem*). Alevis had historically suffered from the centralization of the Ottoman Empire beginning from the sixteenth century. Their suppression took the form of systematic Islamization and Turkification in the 19th century (Lord 2017, 55-6). This trend was also followed in republican nation-building despite relief from persecution. Sunni Islam would be a major component of the national identity and the Directorate of Religious Affairs (DRA), which was established in 1923 to control religious activities in the country, would not accept Alevism as a separate belief system. The DRA persists that Alevism is a branch of Islam and denies official status to the *cemevi*. Moreover, due to the oppression Alevis faced for centuries, *cemevi* does not display a specific architectural typology; in the villages the houses of the clerics -called *dede*- had been used for *cem* gatherings.

As a result of the continuous exclusion, Alevism maintained its rural character up until the second half of the 20th century. Similar to other parts of the developing world, Turkish metropolises experienced massive rural to urban migration after the 1950s. Major cities were quickly surrounded with squatter settlements built illegally on public land. The squatter neighborhoods were seen as a threat to the urban order especially with the rise of social movements across the country (Batuman 2006). In this context, Alevi neighborhoods in the squatter areas were marked by left wing politics ranging from left-of-center Republican People's Party to clandestine socialist organizations in the 1970s.

The 1980s witnessed a shift in urbanization policies in Turkey: building amnesties allowed the replacement of single-story squatter homes into 4-5 story apartment buildings

[1] The interviews are numbered to maintain anonymity of the interviewees from the NGOs. Interview 1: representative from Hacı Bektaş Veli Anadolu Kültür Vakfı (26.10.2019), Interview 2: user of Şakirpaşa Cemevi (26.10.2019), Interview 3: representatives from Alevi Kültür Dernekleri (25.10.2019), Interview 4: Nusayri representative from the Alevi Platform (25.10.2019); Interview 5: architect Serhat Nisanoğlu (26.10.2019).

(Işık and Pınarcıoğlu 2001, 161-65). This process also transformed the old squatters into an urban petty bourgeoisie demanding recognition. The majority of this new class would provide the initial base of Islamism in the 1990s (Batuman 2018, 64-66). In a similar way, Alevis also began to raise demands for recognition of their rituals and practices, insisting on their difference from Sunni Islam. This process in which new Alevi organizations were founded and new debates on Alevi identity flourished has been labelled as "Alevi renaissance" (White and Jongerden 2003, Part IV).

The architecture of *cemevi* has also become a topic of investigation in the 1990s, parallel to attempts at promoting modern designs addressing contemporary needs (Andersen 2015). This was an urgent need on the one hand due to the increasing prominence of identity politics (not unlike the contemporaneous expansion of intellectual debates among Islamists). But it was also due to the urbanization of Alevism, which, for centuries maintained a rural character. Within this context, *cemevi* assumed the function of representing Alevi identity beyond faith, encompassing educational and cultural activities attended by even non-practicing Alevis (Akın 1996; Aslan 2015).

2. ISLAMIST GOVERNMENT AND ALEVISM: AN ARCHITECTURAL ATTEMPT AT ASSIMILATION

The early years of the AKP in power was a fierce struggle against the secularist establishment led by the military. In its quest for power, the AKP allied with different political actors ranging from liberals to nationalists depending on the immediate needs of the conjuncture. Thus, the AKP was attentive to Alevi demands in the early years of its rule and a series of workshops were organized toward an "Alevi opening" in 2009-2010 (Alemdar and Çorbacıoğlu 2012). The workshops did not achieve any result and they were dropped from the agenda after the elections in 2011, which marked the clear victory of the Islamist government over the secularist establishment. A new initiative emerged in 2013, spearheaded by the Gülen movement, the largest among Turkish Islamist groups with international network and influences. The Gülen movement saw itself an equal partner of the AKP since it provided well-educated cadres which were vital to take over the bureaucracy (Turam, 2007; Hendrick, 2013). The cooperation between the two parties later turned into a deadly clash and led to a failed military coup in 2016, in which Gülenist officers played an important role. The new initiative towards Alevis involved mosque-*cemevi* complexes, with the claim to serve the association of beliefs. The first of these was begun construction in Tuzluçayır, a low-income Alevi quarter in Ankara, in September 2013. However, the project was perceived as an attempt to force the Alevis to attend the mosque and was met with opposition from some Alevi organizations, although some others endorsed it (Mutluer 2014: 155-6).

The mosque-*cemevi* complex proposed for Tuzluçayır comprises three main components: mosque, *cemevi* and *aşevi* (soup kitchen) organized around a courtyard.[2] While the former two spaces are for religious performance, the *aşevi* is a traditional part of Alevi culture. Yet, within the current conditions of Turkish urbanization, the emphasis put on *aşevi* as a connector between mosque and *cemevi,* rather than an extension of the latter, dislocates it and places within the context of charity activities of the Islamist municipalities. The architecture of the complex embodies references to the Mevlana Shrine in Konya, the center of the Sufi order, where its patron saint Celaleddin Rumi lived in the thirteenth century. Embodying his tomb as well, the shrine enjoyed imperial patronage in the sixteenth century due to the order's pro-

[2] The analysis of the building I am presenting here has previously been published in Author (2018, 49-50).

establishment stance. The choice of Mevlana for inspiration is not a coincidence since he is today recognized as an advocate of humanism and tolerance.

The Mevlana shrine, especially its sixteenth century extension comprises a prismatic mass with two main halls (a prayer hall and a *semahane* for the order's trademark whirling ceremony), covered by identical domes with octagonal drums. There is a minaret attached to the western wall, which was later confined within the building with later extensions. The mosque-*cemevi* complex interestingly seems to emulate this juxtaposition within a shared courtyard, if not the same building. Nevertheless, it is hard to say that the two spaces of worship are treated equally in this scheme. The architectural form of dome is allocated only to the mosque and it is taller than the polygonal hipped roof of the *cemevi*. While the *cemevi* is accessed only through the courtyard, there is a direct entrance to the mosque from the street. Thus, the Sunni worshippers do not need to use the common courtyard. The courtyard is a characteristic feature of the traditional Turkish mosques and when they exist, they contain the main gate to the prayer hall. That is, the courtyard always has visual access to the interior through the gate as well as windows. Yet, here, the mosque space, although it has a lesser door to the courtyard, is cut off from this unifying open space with the walls of the staircase to the minaret. The minaret, unconventionally, yet resembling the current condition of the one in Mevlana shrine, is within the mosque massing, towering over the courtyard.

Figure 1. The abandoned condition of the mosque-cemevi complex

While protests continued in Tuzluçayır, the government pushed the construction, which was only possible with constant police presence (Yürekli 2016, 284). Although the government was eager to finish the building despite protests from the locals, the clash that escalated between the AKP and the Gülen movement suddenly rendered the project obsolete. Construction was stopped and the building was sealed (Figure 1). The municipality decided to demolish the complex finally responding to the locals' legal applications calling for the cancellation of the project. Nevertheless, the violent attempt to implement the mosque-cemevi complexes led to convergence among various Alevi groups and organizations.

3. ENCOUNTER OF ALEVISMS

3.1. The urban context of Adana

Here, I shall move on to the context of my inquiry, which is the city of Adana. Adana was an important settlement in the historical region of Cilica. The city is the center of the fertile Çukurova plain and currently has a population of 1.7 million. The expansion of large farms and the emergence of cotton-based industry triggered social conflict in the late 19th century, which resulted in massacres of the Armenians in 1909. While the Armenian population diminished especially after 1915, the local population comprised Turks and Arabs; the latter was identified as Nusayri-Alawites. The belief system of the Nusayri is closer to Shiism and shares very little with both Sunni Islam and the heterodoxy of Alevism (Winter 2016). Approximately 300,000 Nuysaris are settled in the southern Turkish provinces of Adana, Mersin and Hatay.

In Adana, much of the community is located in the southern fringes of the city, where their major religious spaces are single-roomed, mudbrick shrines (*ziyaret*) that are built and named to mark the burial places of important religious figures.

Adana also experienced massive rural-to-urban migration in the postwar period. The influx of migrants from Eastern Anatolian villages included Turkish and Kurdish Alevis. Moreover, the massacres in smaller Anatolian towns against Alevis also resulted in middle-class Alevi migration into Adana. Finally, with the escalation of armed conflict between the Kurdish insurgents and the Turkish military in the 1990s triggered a new wave of -this time forced- migration, in which Adana was one of the major destinations.

Within this context, the 1990s was a scene for significant urban transformations leading to interactions among these minority groups. The arrival of impoverished Kurdish immigrants triggered ethnic tensions between the Kurdish and Arab minorities as the former arrived in the southern districts where the latter were historically settled. Meanwhile, middle-class Nusayri began to move to the modern districts of the city in the north (Keser 2008, 123-40). Alevi identity, which had historically been concealed in the public sphere, served as a mediator for the Kurdish Alevi in the face of anti-Kurdish hostility.

As I have mentioned earlier, all ethnic and religious groups were affected by identity politics and demanded some level of recognition in the 1990s. The most striking aspect of this was the architecture of the shrines, which were denied official status whether it be the *cemevi* of the Alevi or the *ziyaret* of the Nusayri. Below, I will discuss the architectures of these shrines and the growing interaction among them through four projects in Adana: two *cemevi* designed in different periods, one recent Nusayri *ziyaret*, and a cultural center under construction to be collectively used by all Alevi groups in the city.

3.2. From shrines to spaces of encounter

Since they are denied official status as religious shrines, the *cemevi* are officially built as cultural centers since the 1990s. The design of the *cemevi* embodies a prevailing tension: on the one hand it is supposed to represent the Alevi identity in the absence of a historical typology. On the other hand, it is required to embody modern architectural solutions to various rituals in addition to *cem* gatherings (such as soup kitchens and funeral facilities) while also acting as a communal space of gathering to attract the non-practicing Alevis. Within this context, the denial of religious status to the *cemevi* turns these buildings into venues with ambiguous -and at times ambitious- architectural programs including libraries, study rooms, exhibition spaces and conference halls as well as butcheries added to kitchens and morgues integrated to funerary spaces. The expanding programs force the *cemevi* to turn into urban community centers rather than religious shrines to the dismay of older generations. The lack of historical precedence opens room for experimentation with architectural idioms, which is effectively pursued with the growing number of architectural competitions.

However, this was not the case in the 1990s. One of the earliest attempts to build a *cemevi* in Adana began with the purchase of a peripheral lot by the Haci Bektas Veli Anadolu Kultur Vakfı in the mid-1990s. The project was designed by an architect based in Ankara towards the end of the decade. The ambitious program of the 6000 m2 building included a *cem* hall on the top floor, a conference hall, a multi-purpose hall equipped for wedding ceremonies, a dining hall with a kitchen, a library, classrooms, exhibition spaces and a morgue. The backyard has a canopy for funerals. While the extent of the program resulted in delays in construction which was finished only in 2014, there is also a stark contrast between the ambitious architectural program and the building's overall image

(Figure 2). From the outside, the building resembles a public building, a school perhaps, with its cubic mass and the hidden skylight of the *cem* hall.

Figure 2. Yüzüncü Yıl Cemevi in Adana

The design dated back to the 1990s illustrates the ambitions regarding the expansion of functions, but it also symptomatically refrains from displaying its identity. It contains liturgic references such as the numbers 3 and 12, which are "visible yet hidden." Nevertheless, the two decades between the conception of the building and its opening witnessed significant transformations that also led to changes in its use. Currently, the large courtyard in front of the building is used for mass gatherings of 15-20 thousand such as *Ashura*, where the cooking as well as distributing the ashure dish takes place. The courtyard also has a raised platform used as a concert stage. The officials in charge of the *cemevi* take pride in the building's use by various groups ranging from Tahtacı Alevis spending winters in the city and summers in their mountain villages to the Sunni Muslims attending the events with curiosity (Interview 1). They emphasize that the *cemevi* is used by various ethnic and religious groups not only for cultural activities such as the popular chess tournaments but even for funerals. Yet, they would not allow for the use of Arabic -which they perceive as an instrument of Sunni oppression- unless the dead is of Arabic origin. The same goes for Kurdish: the language is reduced to mother tongue, where Turkish, Kurdish and Arabic are treated equally.

The second example is a *cemevi* located in a mixed neighborhood with Nusayri landowners and (mostly Kurdish) Alevi migrants. It was designed and built by the municipality in 2018. The three-floor building has 1280 square meters of floor area, and has a dining hall on the first floor, classrooms on the second floor and the *cem* hall on top. Although the conical skylight is also not visible from the outside, the *cem* hall is indicated within the façade organization (Figure 3). The building represents a negotiation between the Alevi and the Nusayri, since it was an undertaking of the Nusayri mayor, who convinced Nusayri landowners for the construction of the *cemevi* here. He was also successful in raising funds among middle-class (mostly Turkish) Alevis to build the *cemevi* in this predominantly Kurdish neighborhood. The members of the community report on their growing integration with the Nusayri neighbors through the example of inter-group marriages which they previously disapproved (Interview 2).

The 1990s also witnessed the emergence of Nusayri NGOs and the transformation of their shrines (Keser 2008, 182-97). The old ones were mudbrick huts with single spaces, sometimes including a grave. The major

Figure 3. Şakirpaşa Cemevi in Adana

ones were frequently visited by pilgrims from the region (Procházka- Eisl and Procházka 2010; Prager 2013). The religious rituals of the Nusayri were generally organized in the courtyards of the houses but larger *ziyarets* were also used. The rituals involve cooking of a special dish (*hrisi*) made with sacrificial meat and its distribution to the community. Another important ritual is condolences, which would take place at the funeral home. In the 1990s, additions were made to *ziyarets*, which sometimes overshadowed the shrines. They embodied architectural programs incorporating practices of communal worship that previously took place in the private spaces of the home. Similar to the transformation of the *cemevi* into urban communal spaces, the Nusayri shrines also expanded in functions with spaces for prayer (which is performed in seated position, unlike *cem*, where it is required to touch the ground), rooms for condolence, dining halls and kitchens with butcheries (Figure 4).

Figure 4. The transformation of Sheikh Ahmed Garib ziyaret in Adana from late 1990s to 2019

These buildings displayed no architectural significance and did not contain cultural facilities such as libraries, conference rooms, etc. like the new *cemevi*. One reason for this was that the Nusayri neighborhoods have always been exclusive and such facilities already exist within the neighborhood. Another reason was that the shrines were destinations of a region-wide pilgrimage network which did not require a recognizable architectural image.

Figure 5. Nebi Nuh ziyaret in Adana

Nevertheless, the new *ziyaret* built at the site of Nebi Nuh (Noah) shrine in 2018, which was the first one designed by a professional architect, is in stark contrast with earlier examples and displays a clear attempt to prioritize its architectural image (Figure 5). The functions in the building are expressed with the differentiation of volumes. While the butchery, the kitchen and the condolence hall are on the ground floor, the main prayer hall on the upper floor is expanded outwards and tilted in both axes. The bold choice to emphasize the prayer hall is further pursued with references to mosque architecture. In addition to the minaret-like unfunctional tower, the prayer hall is sky-lit with a sliced dome. In this way, the religious symbolism of the dome is appropriated yet detached from its Sunni connotations through its

deconstruction. Moreover, the architect has presented her project in a professional journal as *"cemevi"*, which is never used for the Nusayri shrines (Baykam 2019). This is a clear attempt to derive legitimization from the public recognition of the *cemevi.*

The last example represents the materialization of the alliance among Alevi groups in Adana. An Alevi Platform was established in the city in 2014 bringing together twenty organizations including major Alevi associations and the Nusayri NGOs. The Platform has been successful in raising a unified voice in political issues. They also managed to improve collaboration in the organization of religious rituals. For the past few years the Ashura has been organized by the Platform instead of the individual organizations (Interview 4). As a result of the growing alliance the platform applied to the municipality demanding a center that they will use collectively, which would function both as a public venue as well as a site for religious rituals. The main functions which have been common in all the examples I have discussed are also present in this proposal. The building, which was designed in 2018 and is still under construction, is organized around a courtyard (Figure 6). The basement houses both the kitchen and the funerary preparation spaces including a morgue. The ground floor contains a dining hall, a condolence room and workshops. The first floor contains spaces for each of the organizations and a conference hall. The cem hall rises as a solid box covered with timber motifs derived from the octagonal Seljuk star. Finally, the front façade of the courtyard is composed of a portico imitating the entrance of the Haci Bektas Veli tomb, a major Alevi pilgrimage site. The architect, who incidentally is of Nusayri origin, has reported on the discussions he had with the representatives of the organizations (Interview 5). According to him, there is a clear tension between the older generation's desire to identify the building as cemevi, primarily a religious building, and those who wish to see it as a public space of gathering. He emphasized that the architectural elements he added are compromises resulting from the negotiations between various parties including different Alevi groups, the architect and the municipality.

Figure 6. Hanedan Cultural Center in Adana

All four of these recently built buildings are ambiguous as institutions. They are officially cultural centers, which makes it possible to negotiate their architectural programs as well as their images. This ambiguity also opens room for negotiating their public perception swinging between religious shrines and inclusive community centers. The interaction among the Alevi groups is best expressed in the gradual unification of the architectural programs of the *cemevi* and the *ziyaret.* Interestingly, even the rituals began to affect each other. The traditional Ashura of the Alevi is increasingly attended by the Nusayri and its emblematic ashure dish is occasionally adopted by the latter, who have increasingly preferred labeling themselves Arab Alevis. In return, the main Nusayri event *Ghadir Hum* (celebrated as Eid al-Ghadir by the Shiites across the Middle East but not by the Alevis in Turkey) is being recognized by the Alevis, who attend the Nusayri celebrations.

CONCLUSION

The interaction among Alevi groups in Adana is initially a response to the current urban political condition in Turkey. All these groups believe that they are "undesirables" under the Islamist AKP and feel the need to collaborate. The insecurity of the minority groups has further escalated with the Syrian civil war, which triggered anxiety among the Alevi and especially the Nusayri who are associated with the Syrian regime by the Islamists. News reports on the use of refugee camps by Jihadist militants are particularly terrifying for them.

The contemporary Turkish metropolis is marked by the increased potential of political dissent latent in the public space despite the authoritarian measures implemented in the wake of the unsuccessful coup. Under these conditions, the specificity of Adana sheltering various minority groups created conditions for an unexpected alliance cutting through ethnicities. The more the government defines Turkish nationalism with reference to Sunni Islam, the more the minority groups turn to Alevism as a unifying identity which is currently displacing centuries-old architectural traditions. The ambiguous status of their shrines, whether it is the *cemevi* or the *ziyaret,* in this context, turns into spaces of association among the hitherto withdrawn minorities of heterodox Islamic beliefs.

PAPER #8.08

HORIZONTAL EXCHANGES AS A DESIGN METHOD. AFRICA URBANISATION AS A CASE STUDY

Rossella Gugliotta[a]
[a]Politecnico di Torino, Turin, Italy

ABSTRACT

Within a globalised world, it is easy to find community problems, especially outside our boundaries, in countries that are growing up quickly. Therefore, there is the tendency, not only for architects, to direct their efforts for the benefit of society; from it, the participatory approach became a tool in the design process. There are different ways to understand participation in the design process, and each of them can lead to different results: in terms of effects on the building and its grade of acceptance. All of it is directed by the mutual exchange of competences and information between the actors inside the process. In all of these dynamics, the architect is playing a role. Moreover, what happens when the community is one of the main actors inside the urbanisation of a country should be the point to address this research. Through the observation of the urbanisation of sub-Saharan countries and the study of European based studio projects inside the continent, is possible to explain how the participatory approach is not just a manner of design but a process ruled by different interactions. The question is not how to involve the community inside the process but who is driving it out, which role the architect is playing. The core issue is localising in which stage of the process the community is taken into consideration. Meanwhile, the bottom-up method is going to be overlaid by a horizontal exchange became essential to question the reason why this kind of method can be useful inside the process of design. Is it the community approach led just by willingness or it is the result of a complex process of interaction? The main issue remains how much this kind of participation may contribute to a useful involvement for the community inside the project. It can be an opportunity for the community to recognise its identity inside the building, or instead can slip into a mere way to publicise an elusive ethic approach.

KEYWORDS

Design process; sub-saharan Africa; exchange; architect role; design method.

INTRODUCTION

Inside the process of urbanisation of Sub-Saharan Africa that is spreading out in the last ten years, the strong involvement of the community is still one of the main bulwarks inside the process of building and construction of the new face of the continent. Considering it as a unique vehicle for a good design inside the region is still a mistake that this research is trying to avoid. Moreover, foreign architectural studios, many of which are European based one, lead most of the projects developed to increase the services inside the continent (Lepik, 2013). For this reason, the comparison of cases study of built educational facilities in Sub-Saharan Africa made by European based studio gives a general overview of the facts and the typical dynamics that are easily employed inside the process of urbanisation of small urban and rural centres. The number of projects carried out from local architect is inconsistent compared with the European. Each of them,

in different ways, address how the architect is actually playing a different role inside the urbanisation of the country and how straight, or sometimes indirect, communication with client and community leads to a different level of involvement and approach to participation processes.
Architect, client and community are the three main actors taken into consideration during the analysis. Each of them shapes the process of design in a different way; moreover, the mutual interactions characterise the results of each project. All the main actors are placed at the same level to understand the transformation inside the continent. The multiple configurations of the relationship that spreads out give to the reader different point of view of the project that, on the surface, have the same purpose: community interest in the first place.
Starting from an overview of the continent and the brand new directions of the participatory process inside marginalised realities the research lead to unlocking a debate about the urbanisation of the continent from a different point of view; not only economy but also from the operative way of doing architecture.

1. COMMUNITY APPROACH

Inside the books of theory of architecture or design, usually, there is no direct relationship between the architect and the community as a user of the project or deterministic actor of design choices. On the contrary, the community is associated with the terms of society. This word was one of the main issue addressed by the prevailing attitude spreading out in the fifty. The collective vision and the political conception of architecture have given rise to a reaction of internal opposition to the entire system of values that are still rediscovered today by social practice (Biraghi, 2019). In "The architecture of reality", Antonio Monestiroli (1999) even defines the function of the architect as the detector of collective reason. Still, Giancarlo de Carlo was one of the promoters, in Italy, of the participation of the community inside the process of design. Not only as an informed person, moreover, as an active actor inside the design; someone that is taking place inside the process and is shaping it (De Carlo, 2013).
In recent years, the theory shifted from a purely participatory approach to overcoming it. Within a globalised world, it is easy to encounter societal problems, especially outside one's borders, in developing countries. Hence the tendency, not only for architects and designers, to direct their efforts for the benefit of society (Tromp, Hekkert, 2019). A significant number of organisations devote their work on communitarian projects implementing and using the community to archive the goals (Abuom, 2005). Numerous critical issues related to a transcultural approach to architecture undoubtedly accompany this vision (Hernandez, 2012). Especially when the debate is moved to an extra-continental environment, the role of the architect inside the process of transition of different culture became essential. The task of the architect became very complicated, especially in the post-colonial context, as Sub-Saharan Africa can be. There is an essential need for mediation inside the design process. Mediation between two cultures (one of the architects and the one of the community) with the purpose, at the same time, to archive adequate spaces and satisfy the need of the society (Hernandez, 2012). In this environment, the participation of the community to the design process can allow the architect to archive goals that he could not reach by himself. Upstream of all, according to reflective practice, the designer is finding himself again, trying to solve a problem that a previous project has done (Tromp, Hekkert, 2019). According to the definition of Tromp and Hekker, social design based its roots on an effect driven design in which the social effect that the designer would like to obtain depends on the analysis of the behaviour of

the community. The context and its analysis are the ones that are shaping the behaviour thought the final artefact. Between these two levels (social effect of the artefact and behaviour around it) is placed the mediation as a definition of common objectives to arrive, through an approach that takes into account the architect and the community, to a final product that meets the vicissitudes required and in which the community can be recognised (Tromp, Hekkert, 2019). Again the world mediation inside the process of design is coming out to underline how deep can be the relation between the process to obtain a specific artefact and the tangible results. Once again, facing a paradigm of being inside the system but against it (Biraghi, 2019), the architect places himself in a central position of mediation and interaction between the parties. The architect remains the subject that deals with the design, understood as a purely technical and disciplinary fact (Armando, Durbiano, 2017). However, the community is taken as an essential element with which to activate relations and cognitive and interpretative dialogues that lead to a conscious design that reflects shared social values. The architect thus aims at a general involvement able to produce changes starting from small projects of activism within the community system that transforms itself from a static actor concerning which to assume a set of values, to a dynamic subject that generates effects on the design system (Lepik, 2010).

2. RESEARCH APPROACH AFRICA

The African continent was, for a long time, a sort of heterotrophy for occidental designers. Especially in the context of architecture after 2000 began to emerge the tendency of "not-for-profit aid-architecture" (Albrecht, 2014). The prevalence of foreign architects building in Africa is connected with a particular situation of architectural education. The range of architectural school is way lower than the European average, and the number of architects cannot supply the needs of the country (Lepik, 2013). Often European studios to validate the project inside a marginalised reality use this kind of sharing processes between the designer and the community. It is often publicised as a method of integration of the artefact inside the cultural environment, using local materials and employing the villagers as shapers of the project. However, this is not still enough to design and build a good architecture that will supply the need of the community. Numerous are the projects made that are not working. Above all, because of the lack of sense of belonging of the artefact to the community. Static buildings that are not keeping the essence of practical use (Di Campo, 2018). Going deeper into the field is possible to understand how many different points of view can be generated by this kind of approach. Sometimes it is just promotion of intention, but in other cases, internal dynamics can lead to a co-shaped result.

Sub-Saharian Africa, as a case study, leads to understanding the dynamic of cooperation project and the participation of the users inside the project. The research is structured in two different part: the identification of a body of knowledge about African projects and the comparison of five cases study. The first part is based on interactions of different parameters that, through the attention on the role of the architect inside the design project, are going to understand how different relations are giving new interpretations of a participatory approach. Moreover, the primary assumption is asking how the relationship between architect and client are shaping the relation that design has with the local community. Projects in the sub-Saharan country give us the condition to study a phenomenon where the community is still one of the major actors inside the processes of the continent. To have a comparable analysis sample is necessary to fix some

specific characteristic that each architecture should observe. The localisation of the intervention and the year of construction is limited to have a general historical frame that can be comparable inside the sub-Saharan continent. Each case study is focused on instruction building realised from 2000 to 2019 (form when the not-for-profit project by Europe begins till nowadays). For instance, other parameters are taken into consideration to amplify the richness of the sample. That information became essential to define the general assessment inside the panorama of the interventions "not for profit" that are spreading out inside the continent. That will not give a detailed analysis but a general frame to define a common tendency and the most common process of design laded by European based architects.

Moreover, it should be clear how the community could be an influencer inside the urbanisation of the continent. In fact, with a variety of approach, the European architect is searching to emphasise a communitarian sense, local tradition and construction typology. The common element is that most of them would like to involve the community inside the process of design and construction of the building. This approach aims to create conventional narratives that will help the community to recognise deserves inside the building. The architecture in this way will be the vehicle of new practices and social engagement, nonetheless a matter of importance for the interpretation of the tradition. The building in itself is a representation of the community that can shape and reframe social asset and dynamics all around (Africa Architecture Culture Identity, 2015). Case of White Elephants is spreading inside the continent. This kind of project is often characterised of a lack of reality inside the socio-economical condition of the environment (Africa Architecture Culture Identity, 2015). The community became an essential subject helping the architect to take some choice and face with the real problem that should be taken into consideration during the design process.

Among the tasks that European architects aim to develop through projects in Africa is to initiate a new aspiration towards the use of effective techniques. The level of engagement of the community assumes particular importance within the production process, not only concerning the development of an identity feeling that allows the recognition of the community within the building but also to open a sort of reflection and re-evaluation of local experiences (Marschall, 1998). All these practices that are defined as participatory are nothing more, for African culture than common practices of discussion within rural villages (Albrecht, 2014). For years, the self-regulating practices of African rural communities without any administrative system have been studied with fascination (Carbone, 2005). Everyone in the community also has a specific role when it comes to design and which the architect must take into account if he wants to establish a constructive dialogue within the community.

3. AFRICAN PROJECTS

The second part of the research is more focused on the direct observation of chosen case studies. Through a compositive analysis and the interview with the architect, it was possible to frame a critic scenario of the Sub-Saharan continent and the European designer in it.

Many projects inside the continent are experimenting process of participation of the local community. The most crucial difference is the level of participation of the citizen in it. The level of involvement and how architects are dealing with the community is different. To have a general framework, are taken into consideration five case studies: Gando Primary school by Françis Kéré, the communitarian school of N'tyani by Caravatti, Gaugorouboru Primary school by LEVS, the

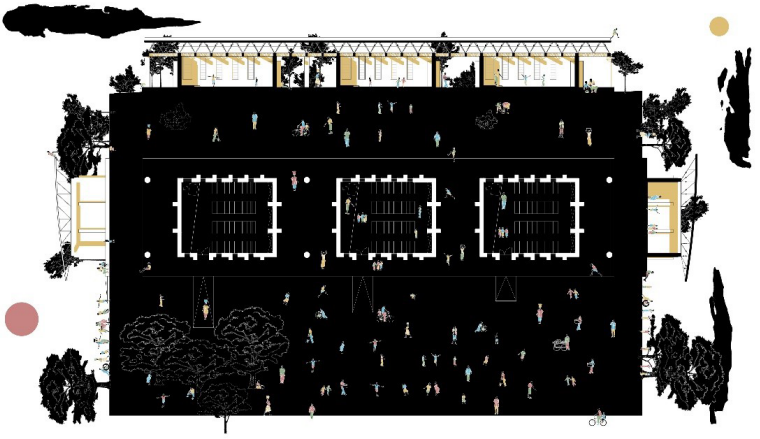

Figure 1. Gando Primary School by Françis Kéré. Source: (Gugliotta R. 2019)

library of Muyinga by BC and 5 Kindergartens by ColectivoMEL. The choice of these cases is led by the willingness of having a brother panorama to understand how different studio, by size and experience in the continent, can have different outcomes on the project. All the studios are European based but apart from the control case (Kéré architect), have not cultural relation with the continent, and some of them were even neophytes in Africa.

As the first case, Françis Kéré reflects the voice outside the chorus against which other designers can be compared. In addition to being widely familiar within the continent, his experience as a citizen of Burkina Faso and designer in the same area, allows him to have a broader general vision and to possess much more in-depth specific skills. With his project of the Gando primary school (Fig. 1), he tried to go deeper inside the process of participation of the community inside the process of design. He knew precisely the need of the community because he was part of it during its life. The same, he was also conscious about the difficulty of getting the community involved in a project coming from outside. The vehiculation of new construction systems, coming from the tradition of the place, were spread out from a long interaction and communication process with the locals. Projet LOCOMAT instructed the men, an agency of the Ministry of Transport promoting the use of local materials and traditional techniques, for making bricks, the children helped transport the stones, and the women supplied water. Each of the members of the community was included to develop belonging and ownership of the building gradually.

Caravatti, a studio in Monza, with projects in Mali since before the early 2000s, presents two types of projects: those carried out for an association of missionaries to which they have been linked for a long time, and those carried out through their own NGO. The Africabougou organisation, which deals with development projects in Malian territory and raising funds for interventions, is recognised in the figure of Emilio and Matteo Caravatti. The association is assimilated directly to designers rather than the studio. Inside the project of the communitarian school of N'tyani, the local community was involved in the design through meetings (an essential method to exchange information) to agree

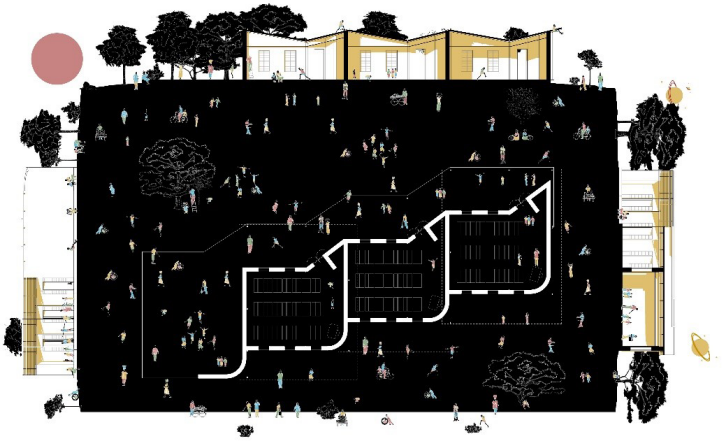

Figure 2. Communitarian School by Caravatti. Source: (Gugliotta R. 2019)

in which times, materials and technologies used. The school was built in raw bricks made by the local population. The interaction that the architect developed inside the community of N'tyani, not only with the primary school (Fig. 2), allows facing a horizontal exchange in which the design is just a small step inside all process of life of the building. They start to develop their project in a territorial grid to have a system of intervention and not just a white mosquito. The building and the community are free to develop by themselves after the intervention.

LEVS, a studio based in Amsterdam and initiated projects in Mali by the figure of Joop van Stigt, as Caravatti holds an NGO, Partners Pays-Dogon, which deals with projects in Mali with a rather significant position concerning the territorial management of interventions. The association plays both the role (client and financial promoter) for which the question remains about the involvement and relevance of the designer in the process that seems, at first glance, to remain marginal, just confined in the design of the object. Besides, where is the community here? Long-lasting relation of architect and community, in this case, is leading the studio to be part also of the community knowing needs and traditions. The same history for Caravatti; instead, they have a different approach when it comes to talking about design and involvement of the community inside the process of development of a new project inside the villages. The Gangouroubouro Primary School (Fig. 3) is mainly composed of a single block with three classrooms and local services. The architect used a "typical Malian" model to build the classroom joint with particular attention on the details of the buildings. In it, the design process leads to an overtaking of the constant dialogue with the community assuming their knowledge built with years inside the continent as detailed enough.

BC architects, a studio directed by two young Belgian designers, have only recently approached the sub-Saharan panorama, boasting numerous workshops and projects in Morocco. Unlike the other two studios, it does not rely on any particular association but is called to design on behalf of ODEDIM NGO, but sees within the process the alternation of many other associations including SATIMO (Belgian NGO) which is

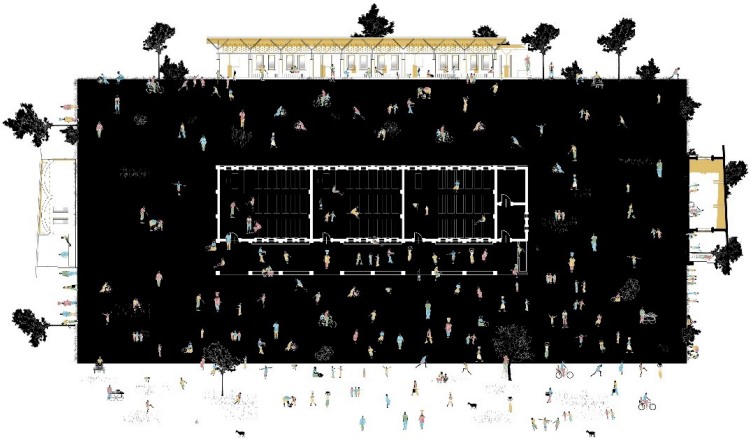

Figure 3. Gangouroubouro Primary School by LEVS. Source: (Gugliotta R. 2019)

responsible for raising funds. Their approach to the project is therefore different, according to an architect-client exchange much more similar to traditional dynamics. The process of engaging the community and the client together became essential to understand how to approach in a first time a different reality. Moreover, workshop and involvement of students inside the processes led to a continuous exchange of knowledge to build the Library of Muyinga (Fig. 4).

The last case study, a project of the Portuguese studio Colectivo MEL in the African continent is examined. They, like BC architects, are not supported by its NGO but they were contacted by a Portuguese organisation operating for

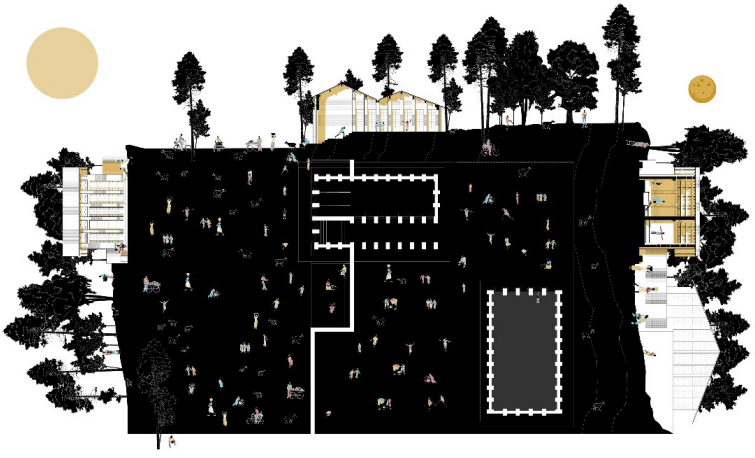

Figure 4. Library of Muyinga by BC architects. Source: (Gugliotta R. 2019)

Figure 5. Kindergartens by Colectivo MEL. Source: (Gugliotta R. 2019)

years in the territory of Guinea-Bissau. In this case, funds raised by the association come from the European Union and the relevance of the client inside the design process is substantial. They became the first interface and the filter between the community and the architect that had no direct relation. For this reason, the project of 5 Kindergartens (Fig. 5), at the end of the construction, does not take all the designed items. The main construction was made by concrete as suggested by the NGO, and at the same time, the community changed the roof cover in straw after the construction with a metal sheet. The traditional in this case was not fitting with the willing of the local.

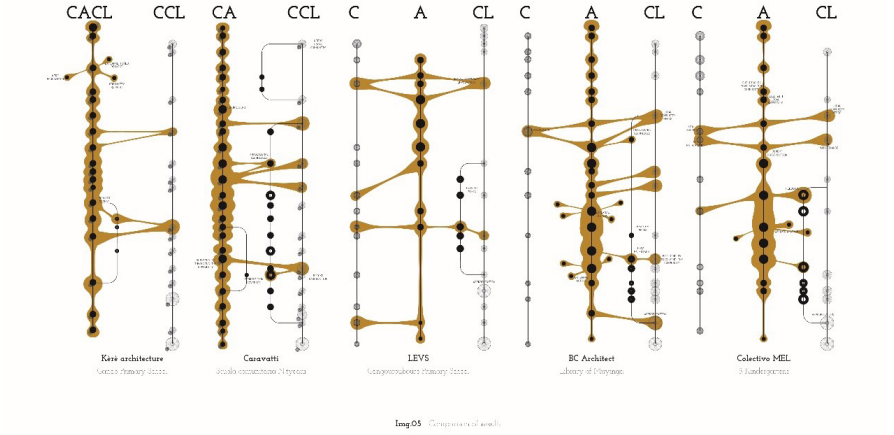

Figure 6. Process comparison. Source: (Gugliotta R. 2019)

Inside the diagram processes (Fig. 6) each relation are showed to understand the approach of the architect inside the design. Each architect has different synergies with the community and the client. Some times they have more than one role: architect, client and member of the community itself. Each studio kept with its strategy a different level of engagement. Sometimes the architect is more present inside the process to deal with the community (Caravatti, Kéré and BC studio) and some others have the client, most of the time NGO, as the most relevant factor inside the process (LEVS and Colectivo MEL). As much as they can share a common characteristic, each studio is approaching differently to the design inside extra-continental reality and the involvement of the community with it.

4. HORIZONTAL EXCHANGE

Each of the studios involved in the inquiry has different approach inside the dynamics with the local community. Sometimes this change of method is leaded from a different involvement of the client inside the process of decision. The customer is often one of the main actors inside the design process of the building. In some case is the one that knows more about the community, it is the one with money, and that is commissioning the intervention.

A particular differentiation occurs in the first instance between architects with a long tradition on the continent and newcomers who approach projects for the first time. The narrative of the reality with which they had to deal is also different. The dynamics of emerging studies are much simpler and easily assimilated to the European context. BC and Colectivo MEL that were analysed in the previous paragraph have a relatively similar relation with the client. Both are depending on it to talk with the community. The difference is henced in dealing with this relation and the stage of involvement of the community. Besides both were approaching for the first time a challenge in the sub-Saharan country, BC architects decide to involve the community from the beginning and keep this relation in different stages of the process: from design to construction. However, Colectivo MEL led heavily from the power of the client, used the community just to keep some knowledge. It was not directly involved inside the consistent part of the process.

The client is a subject with high power but not always definable. Certainly, the obviousness of considering the local community as a client does not provide any change of position concerning the European situation. Instead, the dynamics scattered out by Françis Kéré and Caravatti gives a different point of view on the process of participation inside the continent. The main issue became to develop a sense of identity of the community inside the entire process. Not only explaining them the reason but make them understand the entire mechanism behind the design of the building without losing their volunteer as an architect. The designer, inside the processes, remains the bearer of a value shared by both (client and local community), becoming mediator among the subjects. Through this, any top-down or bottom-up process is eliminated in order to establish dialogue and linear exchange between subjects. The architect becomes an interpreter and translator. Within mediation brings values and contributions to projects that take into account the needs of a client, even if latent, but which at the same time are respectful of the local community. It is not so much a question of community participation in the projects as the involvement of the community itself to enable it to become an active part. The main problem of welfare projects in sub-Saharan Africa derives from the excessive power of the client and the use of the term "local community involvement" as a valid element of the project.

On the contrary, a shared and functional approach by the architect can contribute

to a different degree of awareness than urbanisation projects. The architect as a mediator is therefore not alienated from his own ability to transmit values within the project, on the contrary, he uses his preferred perspective point to observe and identify the strategy of action that allows him to carry out the work through the involvement of community and client. A mediation that turns into a communicative practice between the subjects were meetings, and discussions aim to transport the architect's knowledge of the project within the process.

CONCLUSION

The participatory approach in these cases is not a method directly employed by the architect in a canonical way. Therefore, it is a process of continuous dialogue that allows the community to be part of the project maintaining the designer as a reference point. The community is taken into consideration as an actor that shape the general scheme, and that will have a future impact on it. Reaching horizontal participation inside the process and balancing the weight of each actor results more important than promoting participation and a bottom-up method. In this way, the community is not forced inside the design and construction processes but accompanied in developing a sense of identity toward architecture. In it, practice does not allow to talk about a simple method that can be systematised but moreover of a practice that can be shared and absorbed in the design process in foreign countries. This permits opening a debate on practice and role of architects outside their cultural frame of knowledge and experience.

ABSTRACT

Sociological distinction explains how certain subjects (individuals and groups) gain an advantage using their *social, economic, cultural,* and *symbolic* capitals according to Bourdieu. In the same way, elements in urban areas use their *qualities* to distinguish themselves in an analogous competition within both the physical and social space.
The clearest of these qualities is *centrality,* which describes the benefits of location and precisely creates the classic distinction between core and outskirts (nowadays measured in time as well).
Urban elements (buildings, for instance) also possess *material quality* – related to their technical properties such as size, habitability, or performance – which gives them advantages in material competition. In the same way, they have *cultural-symbolic quality* – referring to the interpretation of their elements such as social appreciation, value, or coherence – which makes them stand out in representative aspects. These two qualities of distinction are used as axes to develop a two-dimensional space to study the elements' positions.
This scheme is applied to housing developments in Porto's urban area (Portugal) in order to analyse their *qualities* (and inequalities). Each ensemble of residential buildings is characterised separately by its *centrality* (in distance and time) and by its material and *cultural-symbolic quality*. The cases of low *centrality, material,* and *cultural-symbolic* quality do not necessarily coincide and then the different types of peripheries do not necessarily overlap.
As explained and exemplified, urban elements have a certain *centrality, material,* and *cultural-symbolic quality*, which are properties related to respective *social, economic,* and *cultural/ symbolic* capitals of their users. This scheme enables discussion of the constructions' and residents' problems at the same time. Thus, research can theoretically circumscribe three types of inequalities: segregation, (energy) poverty, and marginalisation.

KEYWORDS

Bourdieu's distinction; peripheries; *inequalities*; architectural quality; Porto (Portugal).

INTRODUCTION

Inequality is defined by the Cambridge Dictionary as an unfair situation in society created by a difference in social status, wealth, or opportunity. In contrast, *quality* is in singular a high standard, whilst *qualities* (in plural) are the characteristics or features of someone or something. These concepts have a different etymological evolution, but a related origin (from 'in-aequalis' and 'qualis'). Thus, their relationship enables research to understand *inequality* as a process when some *qualities* are missing, or when a certain lack of *quality* exists, in the case of the built environment, *architectural quality*.

This approach is also relevant to understand peripheries in a broad sense, not only as a location separated from the centre, but a territory with a lack of certain qualities, for instance, centrality in the case of geographical peripheries. Similarly, the economic peripheries could be defined by their lack of economic assets and the social peripheries by their integration problems. For these reasons, the characteristics and features of the elements emerge as a critical factor to understand inequalities, especially in territories defined by their differences, like peripheries.

To study these complex and unequal situations, this research takes advantage of a methodological framework based on the differences: Bourdieu's sociological distinction. Firstly, this paper explains Bourdieu's theory and its relevance to architecture. Secondly, a theoretical adaptation is developed to analyse the qualities of social distinction in architecture. Thirdly, this framework is applied to housing developments in Porto's urban area, discussing the empirical results. Finally, this paper analyses the general implications of this approach and explains its main conclusions and lines of research.

1.BOURDIEU'S SOCIOLOGICAL DISTINCTION AND ADAPTATION TO ARCHITECTURE

Sociological distinction explains how certain subjects (individuals and groups) gain an advantage using their *economic, cultural, symbolic,* and *social capitals,* which constitute the interdependent axes of distinction (Bourdieu 1979). The capitals employed in the social struggle are materialised in several objects of distinction: possessions – among them buildings -, activities, education, etc. This objects act on one or several of the abovementioned axes, creating differences in society.

According to Bourdieu, social differences are not only structured by a one-dimensional linear scale, but rather occur in a social space mainly structured by two composed axes (Fig. 1). Firstly, there is the *total volume of capital,* the amount of economic and cultural capital that an agent possesses. Secondly, there is the *composition of capital,* which takes into account the differences between them, mainly in terms of economic and cultural capital. In addition, social and symbolic capitals also act in the same social scheme. Social capital is not just the number of people that a person knows, but rather the sum of these people's capitals, which constitutes the network to which a person has access and can eventually mobilise. Similarly, the symbolic capital requires some other capitals and a certain position to exert its influence, namely in terms of social recognition. The positions in the social space thus defined are also affected by the length of their permanence in the same place and by the trajectory of the subjects (and their ascendants) in the social space.

Thus, Bourdieu's theory overtakes the simplistic approach based on economy, to build a complete system to understand positions in society with their *effets de lieu* (effects of place). Not only do the upper classes (++) have money (*economic capital*): to maintain their hegemonic situation they also have a high cultural level (*cultural capita*l), relationships with other influential people (*social capital*), and the iconic character of their status (*symbolic capital)*. Moreover, they usually get more advantages, acquiring exclusive pieces and patronising professionals of high cultural capitals. In the same way, medium and lower classes are characterised by their total volume of capital, but with important differences according to their capital composition, and also, their habits, tastes, and ideologies (*habitus*). This variation of *habitus* can be illustrated by industrial bourgeoisie (+-) vs. intellectuals (-+) and urban workers vs. peasants, which

was highlighted in several empirical studies in France (Bourdieu 1979).

Lately, this same approach has been used in other countries with relevant results. In Portugal, the populations of Porto's neighbourhoods were characterised by their capitals and built environment, finding a strong correlation between their habits and their economic, cultural, social, and symbolic capitals (Borges Pereira 2018 and 2016). In Spain, Bourdieu's distinction has served to explain how social capital and other characteristics are shared between rural and urban territories (Lamela 2014).

As mentioned, Bourdieu's distinction is a complex and holistic framework to understand reality that is applicable to many approaches: from the sociology of people themselves, to the space they occupy and the elements they use, issues with an intense relationship with architecture and urban studies. Thus, buildings are one of the most significant elements of social distinction. Residences, for instance, are probably the biggest investment that many subjects make in their life (Lizancos 2000). This is why they carefully decide if a building's elements give the appropriate (social) representation of them (Villanova, Leite, and Raposo 1995). As constructions have and use different features for distinction, they also become subjects of these social processes and play the same role, struggling in social space as a representation of their users. This is very interesting because then, research can describe buildings by their characteristics, emphasising high *qualities* and also claiming against their *inequalities*. In the same way as people do, the constructions in urban areas use their qualities to distinguish themselves in an analogous competition within both the physical and the social space.

This study about built elements changes the terminology to *'quality'* and *'qualities'* because these terms are more appropriate and widely used in the architectural field. This also coincides, as mentioned, with what is known as *quality* in design and, more precisely, *architectural quality*. Bourdieu's distinction uses the term *capital* because it refers to power relationships in society, which would not be exactly the case of buildings (even if sometimes this metaphorical use can be found). In other words, the buildings' *qualities* constitute important *capitals* for their users; there is an evident and strong connexion between them, but *'capital'* remains in the sphere of people and *'quality'* in the field of architecture.

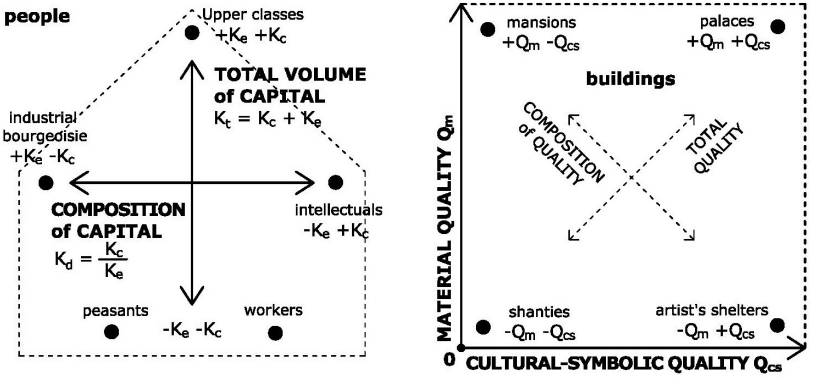

Figure 1, 2. Bourdieu's social space to study people, proposed social space to study buildings. Source: Authors

Quality is an essential discussion in architecture. For instance, it was the topic of the Davos Declaration of 2018 *Towards a high-quality Baukultur for Europe,* adopted by the European ministers of culture (Forte 2019). This topic is especially crucial in peripheries which have a significant lack of architectural values. As Bourdieu's distinction focuses on the differences and relationships, it is particularly suitable to characterise peripheries. Firstly, because they are characterised by their difference from average and central areas and, secondly, due to their particular lack of homogeneity. In these spaces, distinction's theoretical framework can better appreciate and process the variations between elements (for instance, in comparison with a typological approach).

1.1. Proposed social space for buildings

Taking into account the abovementioned Bourdieusian framework and its multiple implications, an analogous analysis matrix has been developed to study buildings in an equivalent social space (Fig. 2). This proposed scheme uses two simple axes, instead of composed ones, for a simpler and more straightforward explanation. Thus, the new scheme is practically a copy of the original one rotated 45º.

The two main axes are the *material quality* - related to users' *economic capital* - and *cultural-symbolic quality* - related to users' *cultural* and *symbolical capital*. These two axes are fully explained in the next section, but they can be respectively presented as related to physical nature (in a materialistic approach, mainly quantitative and geometric) and social interpretation (in a cultural and symbolic approach, mainly qualitative).

This two-dimensional quality space is easy to understand if extreme cases are explained. In housing, they would be: palaces (++), mansions (+-), artists' shelters (-+), and shanties (--) (Fig. 2). The proposed scheme does not make a difference in the lower positions in the composition of quality – which made sense for people -, because no consequences were detected in built results. Precarious constructions are so limited that the composition of quality does not seem to introduce variations.

It is also essential to know that many elements are contributing to both axes at the same time, but in different manners (i.e. a stone wall is a materialistic asset by its durability and thermic performance and, at the same time and for other reasons, it is a cultural-symbolic asset because of its semiology and social appreciation). This two-dimensional scheme about the quality of the built element itself can be completed by a third axis: *centrality*. This geographical quality of the place - related to the *social capital* of users - completes the proposed scheme of quality.

2. QUALITIES OF SOCIAL DISTINCTION IN ARCHITECTURE

This relationship between architecture and social distinction has been previously highlighted in scientific literature. Several studies have shown how returned migrants (once belonging to the lower classes) take into account processes related to Bourdieu's distinction in Northern Portugal (Villanova, Leite, and Raposo 1995) and in Galicia, Spain (Lizancos 2000). The elements, symbols, and composition of these migrants' houses are, apart from obvious cultural and necessity issues, consequence of the *effets de lieu* (effects of place) in social space. The results are affected by the promoters' current social position, as well as their previous one, their path in the social space, and the time spent in each position (Borges Pereira 2018). Other studies use Bourdieu's distinction to explain social influence in architectural design, like the preference for neoclassical design among the upper classes in Brazil (Pulici 2016).

In all these cases, there is a far-reaching discussion about style, taste, and what is

and how to measure *architectural quality*, a controversial issue since nowadays. The fact that the buildings' *quality* is normally measured on an academic one-dimensional scale hides a more complex reality, which this research tries to unveil. To achieve this, some preliminary considerations have to be made. Firstly, the proposed scheme serves to explained erudite academic architecture – the one with *significant material* and *cultural-symbolic quality*. This is a non-especial part of the social space, then comparable to other categories of buildings and, evidently, the one in a privileged position. Secondly, this research is focused on the understanding of general and average *qualities*; in this way, it formulates a basic but sufficient composition of variables for its objectives.

This approach aims to preliminarily explain the main inequalities between constructions. It can still be developed with more variables to better characterise other cases: specimens nearer in the social space, other buildings with other functions apart from housing, or public spaces (which are secondarily taken into account now). Logically, these general and average qualities do not study issues of composition or creativity which are essential in art and the history of art. Similarly, neither do they pay attention to security and structural integrity, which are relevant issues in the analysis of precarious constructions. This formulation has to be understood then in its general purposes, in a compatible coexistence with other approaches and possible specific evolutions. By taking these considerations into account, the different *qualities* can be now characterised to understand how the lack of them creates *inequalities*.

2.1. Centrality

The clearest of these qualities is centrality, which describes the benefits of location and, precisely, creates the classic distinction between core and outskirts. Apart from the geographic approach based on a distance between each point to the centre, centrality should be nowadays measured in time as well, according to the different means of transport available for each itinerary: walking, bicycle, car, public transportation, etc. This property is defined concerning a specified centre: the nearer, the better; but other similar features like general accessibility could be more adequate in the case of polycentric systems.

A deeper analysis of this location's quality should also be complemented with the difficulties and barriers (disabled access, slopes, stairs, lack of frequency, insecurity, etc). It also has to take into account the symbolical effects of the (social) barriers to understand the perceived *centrality*.

2.2. Material quality

Urban elements, residential buildings for instance, also possess *material quality* which is related to their technical properties, which give them advantages in the social competition in materialistic terms. These characteristics are based on the physical nature of the elements and are mainly quantitative and/or dependant on their geometry. This makes them quite objective and stable. The basic approach to housing *quality* in this study is carried out using size, *habitability* and *energetic performance* as variables.

Size refers to the total area of dwellings which includes the usable and constructed area, both with advantages for users. Dwellings with a certain amount of rooms should be compared to equivalent dwellings, but more rooms and auxiliary spaces also normally represent an advantage, as well as higher ceilings. As size analyses part of the *habitability,* the latter variable refers mainly to the shape and functionality of the spaces, their relationship with air, sun, and views at the façade, the dimensions of the exterior adjacent spaces, and their accessibility. Basic assessment of *energetic performance* provides an idea of

its potential to reduce expenses, energy, and carbon emissions.
Some of these three variables which form material quality are mutually contradictory (e.g. size and habitability tend to decrease energetic performance). Thus, a high material quality requires a balance between them and smart strategies. Moreover, for a deeper analysis, components like energy consumption, annual expenses, and carbon emissions should be studied separately and other properties like construction costs, sustainability, thermal comfort, utility, and durability should be taken into account.

2.3. Cultural-symbolic quality

In the same way, buildings have *cultural-symbolic quality* which makes them stand out in representative aspects. These characteristics are based on the social interpretation of their elements and are mainly qualitative and dependant on value judgements. This makes them relative to the society and sometimes partially subjective. *Cultural* and *symbolic* fields are conceptually different (and related to different capitals of their users), though they are difficult to separate from each other. In architecture, they usually act at the same time, which is why this study maintains the double designation of the axis.
The basic approach of this study is carried out using *social appreciation*, *value,* and *coherence* as basic variables to measure *cultural-symbolic quality*. Social appreciation is analysed taking into account elements widely valued by society, which can be qualitatively revealed in opinions, news, and narratives about buildings. *Value* is a theoretical selling price on the market, calculated following the rules of real estate valuation: an average or proportional approximation of a similar property's price in the same area. *Coherence* analyses the symbols, signs, and composition which generate meanings and define (or not) a coherent style.
In a deeper study, social appreciation should be divided into different groups or classes to take into account the respective tastes. In addition, the composition and aesthetics (coherence) should be analysed in comparison to previous and current fashion and trends in design.

2.4. An analogous social space of buildings using Bourdieu's theories

As explained previously, this research proposed a two-dimensional social space (Fig. 2) to study buildings using the explained *material* and *cultural-symbolic qualities* as its main axes, which encapsulate several variables of measurement themselves. The site's *centrality* could be added to form a three-dimensional space to study built *qualities* – which has problems of visualisation -, or analysed at the side for a clearer representation.
In this scheme, each building or group of buildings is represented by a point according to their properties of distinction. The points are placed in more or less privileged areas of the social space. This allows researchers to define and characterise *geographical, economic,* and *social peripheries* according to their lack of a specific property: respectively, *centrality, material,* or *cultural-symbolic quality.*
Moreover, as each case is a point according to these three *qualities*, any improvement (a new infrastructure or service that increases accessibility, a refurbishment of the physical conditions, or an aesthetical renovation) or deterioration produces a displacement of the point, which can be studied as a *vector* of change with a certain *direction* and *intensity.*
This study of the positions through the social space was extensively developed by Bourdieu, as well as the effect of time on each position, which affects the recognition and acceptance of a certain position (Bourdieu 1979). In an analogous application, this effect of time means, for instance, that old landmarks usually have a greater symbolism than new built icons, even in the case of an equivalent

exceptional design, taking advantage then of a greater *cultural-symbolic quality.* In contrast, the same effect of time could be seen in some historically precarious areas which, after a process of requalification with elements theoretically appreciated by society, are still connoted and considered to be of low *cultural-symbolical quality*. The limited space of this paper makes it impossible to deepen these discussions, but some of them are noted at the end as lines of research.

3. APPLICATION IN THE CASE OF PORTO'S URBAN AREA

In order to illustrate and validate this theoretical development to study territories' built (ine)qualities, this scheme is applied to housing developments in Porto's urban area (Portugal). It is important to highlight that this is a preliminary and basic application of Bourdieu's distinction. This study is effective and useful enough to be an introduction to the use of this theoretical framework in built quality assessment, and it is open to further developments. The means are adapted to the main purpose of the research: studying if urban elements' *qualities* and *inequalities* correspond to an old but still canonical one-dimensional centre-periphery distribution; or, on the contrary, the introduction of the other axes improves the understanding of their patterns and nature.

For this exemplification, a small number of case studies (10 housing developments) have been chosen in a sector of the Porto's urban area. The city of Porto is a well-known example because it has been widely studied in its built and social conditions, especially about gentrification (Alves 2016) and social-class structure using Bourdieu's theories (Borges Pereira 2018). This medium-sized city occupies a central position in its urban area, which is highly affected for it, following a natural urban process of growth by rings (naturally modified by geography and pre-existences) like many other cities in Europe.

The case studies belong to different municipalities (Porto, Maia, and Valongo) and they illustrate different urban contexts - the central compact city, the peripheral neighbourhoods, the secondary centres, and the spaces between them. They do not try to be exhaustive of all situations or a representation or summary of the urban area. They only have an illustrative character to apply the methodology, as well as to study if some of them are examples which do not follow a canonical centre-periphery distribution of quality.

Some of the case studies are well-known and deeply studied examples, such as the Bouça neighbourhood by Álvaro Siza (Vale 2018), the Cardosas Square (Alves 2016) and the social neighbourhoods of Amial and Paranhos (Borges Pereira 2016 and 2018). Though all these approaches and information have been taken into account, the aim of this research is the preliminary characterisation according to some basic variables. Thus, information about the housing developments has been homogenised on the rest of cases using open sources: e.g. cartography, press, and advertisements.

As mentioned, the research is focused on general and average qualities. Due to this, quite separate cases in the social space have been chosen to illustrate the methodology. Extreme examples (like luxury houses on the seafront and *ilhas,* precarious working-class settlements inside blocks) are avoided in order to not eclipse the less intense but more interesting inequalities between the examples.

Every ensemble of residential buildings is characterised separately by its c*entrality, material,* and *cultural-symbolic quality,* each of these properties measured in turn by several secondary variables, as previously mentioned. Each case is ranked among the others according to both secondary variables

and main *qualities,* a simple and effective technique, which is sufficient and valid for this introduction. This binary comparison between specimens means a loss of accuracy (which is not needed) but avoids the difficult task of defining exact units and scales in the case of qualitative variables, making the research feasible. Criteria for each property and variable are explained hereafter, as well as the process and the empirical result. Naturally, other criteria could produce different results in the detail, but the general view is maintained if a secondary variable is deleted or changed in a further development, because the variables are quite interdependent (e.g. *centrality* measured in *time* depends on speed and *distance*).

3.1. Centrality

This property only depends on the site's location in comparison to a central point. Porto has a clear centre in terms of symbolism, tourism, and functionality: the area between the guildhall, the cathedral, and the points of maximum accessibility (Trindade e São Bento stations). One of the cases is in the middle of this area. For the others, the distance has been calculated using the tool *Directions of GoogleMaps*, with the option 'walking' and taking the first option. This distance is almost representative to the time by walking and on a bicycle. For the time in a private vehicle and on public transportation, these two options have been chosen in *Directions* on an afternoon on a weekday. Every case is ranked using the three variables (Tab. 1) and centrality (Fig. 4), using decimals to solve parities. Note that, evidently, the cases' positions by walking, on car, or on public transportation have variations.

3.2. Material quality

The technical qualities depend on buildings' spaces and characteristics (Fig. 3). A representative type of dwelling is used to measure size, habitability and energetic performance. The size has been calculated using its footprint area. The relative position in habitability is obtained by a comparison of spaces according to their shape, functionality, air, sun, and views. Finally, buildings are ordered by an indirect analysis of energetic performance: orientation, exposure, form factor, glazing ratio, window quality, and typical insulation. Every case is ranked using the variables (Tab. 2) and the material quality (Fig. 4).

10º	J	10,3	I	30'	H	48'

Table 1. Housing developments in the NW sector of Porto's urban area. Ranked by centrality. Source: Authors

3.3. Cultural-symbolic quality

This property was studied on the available information from visits, the external view (Fig. 3), the news, articles, and advertisements. In a representative type, the research studied social appreciation, value, and significance. The social appreciation has been analysed using public valorisation of the elements (news, articles). Value is a price on the market, according to real estate valuation (adverts). Coherence analyses the symbols, signs, and composition which generate meanings and defined a style. Cases are ranked using the three variables (Tab. 2) and this property (Fig. 4), solving parities by analogy.

3.4. Discussion of the results

The results presented together in the social space (Fig. 4) show the complexity of reality. Cases E/J/F are in the lower positions, cases D/A are in the upper ones, and the rest are on average around the diagonal, except case B, with non-material priorities. Thus, clusters can be found. The majority of cases do not occupy

the same place on the three axes: specimens with high qualities also have regular results in some variables. Specimens with low qualities do not coincide either, neither the different peripheries.

DISCUSSION OF QUALITIES' IMPLICATIONS IN SOCIAL SPACE AND CONCLUSIONS

As explained and exemplified, urban elements have a certain centrality, material, and cultural-symbolic quality, which are related to the capital of their users. Centrality contributes to social capital because it facilitates their users' relationships, especially with powerful people. Material quality of buildings is an economic asset for their users. Cultural-symbolic quality is evidently related to the homonymous capitals as explained before. Thus, constructions' and users' problems can be studied together and buildings' *requalification* (improvement of its qualities) can be linked to people's social ascension (Fig. 5).

This research can then evidently circumscribe three types of theoretical inequalities, such as *segregation,* (energy) *poverty,* and *marginalisation.* Thus, respective solutions appeared: accessibility improvement (infrastructures or services), material requalification (energetic rehabilitation), and cultural-symbolic requalification (symbolic renovation and interpretation). These three dimensions should not be neglected to get a real and holistic improvement. Architects should be aware of their social responsibility and limitations: buildings are major objects of distinction for their users, for good and for bad; but they are not the only one: other social measures must be implemented to reduce inequalities.

In conclusion, this theoretical and empirical research shows the applicability and relevance of Bourdieu's distinction in architecture and urbanism to study inequalities, especially in peripheries. Firstly, it validates this methodology based on buildings' qualities, unveiling social processes in architecture. Secondly it offers a clear representation of the results. Thirdly, it enables the discussion of buildings' and users' inequalities at the same time. And fourthly, it defines their problems - segregation, (energy) poverty, and marginalisation – and solutions - accessibility, material, and cultural-symbolic requalification. Finally, further developments should be made in several lines of research: quantification of the qualities per axis, the use of more variables, a deep analysis of the contradictions and effects of time, a deeper discussion of distinction's implications in architecture, and more case studies in different contexts.

PAPER #8.10

UNIVERSITY-COMMUNITY PARTNERSHIP TO ADDRESS FLOOD RESILIENCE AND COMMUNITY VITALITY

Lisa D. Iulo[a]
[a]Pennslyvania State University, University Park, PA

ABSTRACT

Inland communities are experiencing recurring flooding from rivers, smaller tributaries and stormwater stresses that are negatively impacting economic and community vitality issues. In the past decade, considerable efforts and funding have been devoted to integrated and innovative solutions to flooding in coastal communities. Although funding may be available to inland communities, application of these funds is limited. Efforts are needed to leverage funding opportunities to accomplish community vitality and flood resilience in inland, river communities. To achieve this, meaningful community engagement must inform a comprehensive portfolio of projects and potential design solutions.

The needs of inland communities in flood prone areas are addressed through a pilot study in Pennsylvania. A transdisciplinary team of researchers from architecture, Earth sciences, law, and philosophy has convened at the Pennsylvania State University, USA, and partnered with a local community in Pennsylvania to explore solutions for community resilience appropriate for regional impacts. This paper synthesizes our preliminary understanding of community-based needs and values, challenges, and knowledge necessary to inform meaningful solutions to economic revitalization and flood resilience. The actions presented - informed by community advisors locally, regionally, and statewide - are varied. Initial findings indicate that interconnected thinking about education, planning, and investment that is informed by research and communication may open doors for values-based, design-oriented project implementation that helps meet community needs while informing regional dynamics.

KEYWORDS

Flooding; resilience; pilot-study; actions; values.

INTRODUCTION

Engagement – with clients, owners, operators, representative building users, or larger community groups – is fundamental to architectural practice and education. Emerging concepts for *whole building, integrated or integrative design process* (WBDG, 7group and Reed, B. 2009) and *regenerative development* (Mang et al 2016) emphasize the need for diverse representation of design team members and stakeholders as central to addressing growing complexity in resilient and sustainable design. Indeed, the question of what to design needs to be driven by "dialog between researchers and user groups" through a process that is "collective," "iterative" and informed by place (Staub and Iulo 2011). Related to these concepts, *transdisciplinary research* has been presented as an approach to solve complex, system-based challenges (Max-Neef 2005; Brandt et al 2013; Irwin et al 2018).

> Transdisciplinary Research is defined as research efforts conducted by investigators from different disciplines working jointly to create new conceptional, theoretical, methodological, and translational innovations that integrate and move beyond discipline-

> specific approaches to address a common problem (Harvard, no date).

Transdisciplinary research is driven by specific, compelling problems and involves participation and integration of information across disciplines as well as non-academic 'ways of knowing' (Schneider and Buser 2018). Ideally, there is a mutually beneficial reciprocity for researchers and stakeholders. Most importantly, in the context of environmental change, transdisciplinary research serves a public purpose – solutions that positively impact the triple-bottom-line of sustainability and that are based on inputs of those impacted by the problems *and* the proposed solutions. Transdisciplinary research seeks solutions based on shared goals, individual contribution, interdependence, and common awareness of conditions. Strong partnerships are essential! This paper presents a University-Community partnership to address community vitality and evolving flood risks. A cross-disciplinary team of researchers from design professions (architecture and landscape architecture), Earth and climate sciences (geography, climatology, hydrology), law and policy, and philosophy have convened at the Pennsylvania State University with the support of the Provost's office and aligned with the University's Strategic Plan and commitment to *Stewarding our Planet's Resources.* This group, the Penn State Initiative for Resilient Communities (PSIRC) partnered with a local community – Selinsgrove, Pennsylvania - to explore solutions for community resilience for that community in the interest of regional (watershed-level) impacts.

1. CASE STUDY DESCRIPTION AND BACKGROUND

Flooding is the most frequent and damaging natural disaster for the State of Pennsylvania, USA (ReadyPA.gov). Flood impacts are exacerbated by more frequent and extreme precipitation events due to climate change and increases in development resulting in larger areas of land impervious to stormwater. Finding appropriate solutions to such impacts is difficult, requiring communities to navigate complex tradeoffs. Decision-makers, including designers, often lack timely access to relevant information and ways of facilitating community dialogue about trade-offs or community priorities. Direct engagement with affected communities can help to ensure that scientific resources address the issues most relevant to what the community values, that community members and decision makers have the knowledge they need to make the decisions that matter to them, and that the design solutions proposed are informed by both science and by the needs of the community. The initiative described herein brings together experts and engagement in a flood-impacted community along the Susquehanna River in Pennsylvania to address flood risk in the interest of community development. The pilot project includes two components: 1) working with a selected Pennsylvania community, the Borough of Selinsgrove, to develop a plan for community climate resilience; and, 2) broadly engaging with stakeholders and decision-makers about flood resilience in riverine communities. Since longevity of engagement and trust are essential to community engagement and collaboration, Selinsgrove was selected for this pilot, in part, because of a history of working with this community and at their request for continued assistance.

1.1. Selinsgrove, PA, USA

The Susquehanna River, its tributaries, and the encompassing watershed(s) are a key component of the regional economy and major contributors to pollution problems in the Chesapeake Bay Watershed. Selinsgrove struggles with similar issues to many other communities regionally. It is representative of many historically and culturally significant small urban centers and agrarian communities

in the Susquehanna River Valley. All are subject to flooding from the river, resulting in economic, environmental, and social stresses. In addition to the primary and more predictable flooding from the Susquehanna, there are several creeks and tributaries that are prone to recurring flooding and erosion that affects the larger watershed. Recently, properties not previously subject to flooding – including a new Borough building and public library – have experienced water inundation due to heavy precipitation and limitations of stormwater infrastructure. At the same time, the Susquehanna River is central to community identity and adds to the quality of life for the residents, as well as presenting a recreational destination for visitors to Selinsgrove and other river communities, contributing to community vitality.

In 2006 students and faculty at Penn State's landscape architecture program, through the Hamer Center for Community Design, designed a master plan for Selinsgrove that considered strengthening major corridors within the community and proposed streetscape and storefront improvements for the central business district area of the main commercial street (Market Street). In particular proposals for a vacated pharmacy building at the center of town were proposed, subsequently resulting in the development of a public plaza, the 'Commons,' now used for community gathering and events. In 2018, the Hamer Center was invited back by Borough leaders to discuss updates to the master plan. Discussions included streetscape improvements for Pine Street, the street intersecting Market Street and connecting the campus of Susquehanna University - a private college - to the commercial district and forging a stronger connection with the Susquehanna River. Borough representatives identified dying retail and the need for economic development as negatively impacting Downtown Selinsgrove. Priorities identified included the need to 1) build capacity for residential development; 2) build the image of a vital downtown; and 3) connect the downtown to Susquehanna University - located within walking distance of the downtown and a primary economic driver in the community. In addition to establishing connections between the downtown and campus, a regional planning approach was desired to address:

- Community quality of life;
- Historic and cultural resources;
- Economic revitalization;
- Human health and wellbeing; and
- sustainability.

The Susquehanna River is seen as central to opportunities for improved quality of life through recreation and as a resource to attract tourism. These opportunities cannot be fully realized without first addressing current flooding and risks associated with future flooding due to climate change. Understanding risks and developing potential solutions are informed by multiple decision-makers. However, deep uncertainty may exist "where decision makers disagree about the appropriate problem framing and how to characterize strategy tradeoffs" (Mayer et al 2017: p107).

2. METHODOLOGY AND LITERATURE REVIEW

Communities in the Susquehanna River Valley and throughout the Chesapeake Bay Watershed face increasingly complex resilience challenges. They have to make hard decisions to sustain their populations and historic downtowns built along rivers, to provide opportunities for economic development, and to ensure resilience to flooding in the face of deeply uncertain climate variability and change. Such decisions require communities to navigate complex trade-offs between competing values and objectives. Yet, decision-makers often lack timely access to relevant information (about flood hazards, for example) and a way to facilitate dialogue about trade-offs and value choices intrinsic to such decisions. Moreover, there is frequently a disconnect

between research and on-the-ground designed solutions that address needs and values and can be implemented by the community and sustained over time. Addressing these challenges requires bridging the gap between science and application through coordinated and interactive planning, community-oriented research, values-informed decision analysis, and design. It also requires an approach that fosters respectful communication and collaboration between diverse sets of experts and affected community stakeholders.

2.1. PSIRC team and approach

Launched in January 2019, Penn State Initiative for Resilient Communities (PSIRC) provides an environment of shared discovery where people can come together to address local resilience challenges of small, riverine communities vulnerable to flood risk. Working with local stakeholders and decision makers, PSIRC provides a way to leverage the resources of the Pennsylvania State University to help make an impact for local communities. By bringing together faculty, students, postdocs, and staff from multiple colleges, diverse disciplines, and established centers and institutes with decision makers and community members, this initiative works towards addressing riverine flooding and other related challenges to build more resilient communities in Pennsylvania and beyond.

PSIRC facilitates a research-driven, transdisciplinary, participatory approach to community resilience, bridging the gap between science and decision support through a solutions-oriented perspective. Borrowing integrative and regenerative design associated with the sustainable building sector and incorporating methods from decision support sciences, we apply a goal-oriented, action-based approach to inform more responsible, community-informed applicable solutions through productive partnerships of diverse professionals and community decision makers.

2.2. Description and rationale for developing mental models for decision support

> Decision support science is the systematic study of target systems intended to inform decision-makers, typically with respect to complex and uncertain situations, through a range of experiments, observations, and organization of empirical and theoretical research (Vezer et al 2018: p2).

Relatedly, "influence diagrams are a graphical tool for mapping the interaction of the various elements of a decision setting" (Hall 2010). Mental models and other forms of influence diagrams can be used as tools in risk- and decision-analyses to:

- Engage experts and others in the decsion-modeling process;
- Model how important decision factors interact;
- Identify key uncertainties that need to be "explicitly modeled" (Ibid).

They can also be used to determine how the public understands the problem and form beliefs about trade-offs. Climate risk management (CRM) strategies, such as those required to address flooding, "include variations of proactive and reactive plans" (Mayer et al 2017: p107) informed by multiple disciplines and areas of expertise.

> A mental model is an internal representation of external reality that is thought to influence reasoning, cognition and decision making. An individual's mental model includes their experiences, assumptions, beliefs and biases about the world (Mayer et al 2017: p108).

A mental model is a representation of how a person thinks about a particular phenomenon. "Mental models are the mechanisms whereby humans are able to generate descriptions of systems purpose and form, explanation of a system functions and observed system states, and predictions of future system states" (Rouse and Morris 1986: 351). Mental models

in the context of climate risk management are used to provide a basis for understanding what individuals and communities understand about the nature of the risks they face, and are used to interpret observations, organize beliefs, and make decisions in different contexts. According to Bessette et al (2017):

Mental models have long been used to analyze how the public uses scientific information and knowledge to form beliefs about risks like climate change. These beliefs are identified through a process of comparing two archetypal mental models: a layperson model and an expert model. Both models are constructed through experiences and social interactions.

Mental models can help to identify gaps or differences in the understanding of decision support scientists and community members. While mental model approaches are often used to identify knowledge that community members need in order to better understand the risks they face, they have also been used to help identify what community members value in order to ensure that scientists provide communities with the knowledge they need to make the decisions that most matter to them. Bessette et al report on the "role of values and worldviews in determining climate risk perceptions and decisions" (2017: p1994). They discuss an "augmented mental model research approach" - the *Values-informed Mental Model* (ViMM) [p1995], to take into consideration both experts' and laypersons' values. ViMM is designed to help ensure that scientific resources address the full range of issues that matter to the community.

2.3. Learning from coastal projects and application of methods to inland flooding

New Orleans, post-Katrina, is presented as a case study to test the ViMM method. The researchers conclude that:

> Just as mental model approaches are designed to identify gaps in understanding. ViMM is intended to help identify gaps in the values used by both the public and experts to understand risk factors and strategies. (Bessette et al 2017: p2002-2003).

Related efforts, engaging experts and the public, are needed to leverage funding and accomplish community vitality and flood resilience in inland communities. Although limitations in the New Orlean's study are identified, the study states that ViMM could "go a long way in informing decision-support processes" (Bessette et al 2017: p2003).

Some aspects of mental models may be generalized, for example, factors related to flooding (Aerts et al 2018; Calgary, no date). However, to be meaningful, decisions about design and implementation of strategies must be informed by specifics of place and appreciation of what the relevant communities value. Towards this end, PSIRC has been collaborating with partners in Selinsgrove to develop a ViMM to inform resilience measures most aligned with the realities of inland riverine flooding in small, agrarian communities. As a first step towards the development of a VIMM, a workshop was convened in Selinsgrove Borough with experts representing community decision-makers, regional and state agencies, and local universities. The purpose of the workshop was to gather information from community advisors on priorities and values associated with community resilience to riverine flooding and to identify factors contributing to community vitality. Following an introductory session, participants were split into one of four randomly assigned groups and circulated between stations to address the following questions:

1. What problems or CHALLENGES face small rivering communities like Selinsgrove or the surrounding region and watershed?
2. What ACTIONS should be taken, now and in the future, to achieve community resilience?

3. How can KNOWLEDGE and information be translated into action - specifically, what information do decision-makers have and what information do they need?
4. What do you VALUE and want to see for river communities in Pennsylvania and the region?

3. OUTCOMES AND DISCUSSION

Findings from this workshop are summarized below.

3.1. Challenges

Although some challenges related to flooding are well documented, there are other challenges to be considered with smaller, often disinvested, cities and communities. Local concerns about economic and community revitalization must take into consideration environmental concerns associated with the river, water quality and stormwater management. Although Susquehanna University is a major economic driver in Selinsgrove Borough, it also provides challenges; The University's population mainly lives and works on campus and is perceived as having little presence downtown. Currently, walkability and attracting/retaining businesses are challenges in the downtown area. Dwindling local tax base are a challenge in Selinsgrove Borough, especially since 50% of properties are tax exempt.

Environmental and infrastructure challenges are often addressed together or interchangeably since Impacts on water quality from stormwater and flooding are a leading challenge in Selinsgrove and other river communities. For example, transportation decisions impact walkability and affect local businesses; Development increases impermeability and strains stormwater infrastructure, while simultaneously constraining space for water quality and quantity control. Therefore, water quality (drinking water), urban stormwater management, and river health are local and regional challenges that need to be considered in relation to one another. Lack of coordination is a related challenge. To address environmental and infrastructure issues, coordinating across municipal boundaries is an issue (infrastructure often crosses municipal boundaries and upstream decisions can impact downstream communities and waterways). Lack of predictability and communication are flood-related challenges that result in deficits in preparedness, regional planning, and oversight of floodplains. In addition, a "sunny day" mentality, leading people to forget flooding happened, can pose a challenge to enacting proactive intervention, cause political inertia, and exacerbate local resistance to change.

Many challenges associated with flooding are considered uncertainties and largely mirror regional and national concerns. These challenges are associated with lack of understanding and/or changing definitions of policy and regulatory environments.[1] Much confusion is associated with FEMA (Federal Emergency Management Administration). In particular, challenges are associated with misunderstanding of FEMA mapping, associated terms and practices, and the implications for development.[2] Moreover, many of the properties in the historic Borough were constructed prior to the initial Flood Insurance Rate Map in 1974 (pre-FIRM) and owners are now confronted with associated flood insurance requirements. Exposure to flooding and/or high and increasing flood insurance premium costs have personal and societal impacts, including potential for deferring flood management/mitigation that results in

[1] A forthcoming paper by Keller et al (2020) relates uncertainty to climate risks and presents a review of "challenges and avenues to overcome them."
[2] FEMA identifies and maps flood hazards and assesses flood risks to guide mitigation actions. Flood hazard mapping is the basis for National Flood Insurance Program (NFIP) regulations and flood insurance requirements. Reference: https://www.fema.gov/national-flood-insurance-program-flood-hazard-mapping
[3] Base Flood Elevation (BFE) is the computed elevation to which floodwater is anticipated to rise, as indicated on Flood Insurance Rater Maps (FIRMS) and flood profiles (FEMA.gov).

damages and/or abandonment of properties, further eroding the tax base and leading to community blight. Property owners willing to mitigate are challenged with questions about what mitigation strategies would lead to reduction in premium amounts, whether to use federally available funds to execute a mitigation project, and what standard they should design to (e.g. how high should a home be elevated above BFE[3] to ensure that they are safe from high water?). Even where FEMA maps are regularly updated, how these maps will change in the future is uncertain. These challenges are related to the most predictable impacts of flooding associated with primary rivers (the Susquehanna and its major tributary Penns Creek). Smaller tributaries (streams, creeks) present a lack of predictability with regard to flooding frequency and inundation levels under current conditions, let alone with exposure to increased rainfall and stormwater runoff. Finally, increases in development and stress on existing sewer and stormwater infrastructure is resulting in unpredictable flooding to properties located outside of documented hazard areas.

Funding is a consistent challenge related to community vitality and flood resilience. Limited or unknown financial resources and unclear benefits discourage people from complying with requirements and pursuing mitigation that could protect their property. Limited communication and coordination is a challenge to larger-scale planning and the ability to capitalize on available funding, contributing to a perception of less available funding from State and Federal sources. There are also challenges associated with aligning available funds with community needs: sources may not match local challenges, it is difficult to combine multiple funding sources in sensible ways, and local municipalities may not have the expertise, experience, or bandwidth to identify and take advantage of funding opportunities.

3.2. Actions

Planning, investment (funding), and education/ engagement are interrelated themes when considering actions to be taken now and in the future. There is a need for planning action across scales (physical and temporal) and jurisdictions. Such planning often must address complex trade-offs. For example, actions are desired that can increase development potential. However, these interests may be in conflict with actions to mitigate flooding. Maintaining floodways as open space- a preferred flood risk reduction measure- has implications for public and private properties, presenting immediate risk to buildings constructed in the flood zone and potentially creating obstructions and increased flooding for others. Moreover, allowing development to occur in designated open space could compromise a municipality's Community Rating System (CRS)[4], resulting in increased insurance rates for everyone with a NFIP (FEMA National Flood Insurance Program) policy. For action to occur at local and regional scale, engagement with and across several political entities is needed. Some actions, such as river and open space conservation, need to be addressed based on watershed rather than political boundaries. Moreover, action should be informed by how nature functions, investing more in green infrastructure (i.e. bioswales, raingardens) and less in grey infrastructure (i.e. storm sewers, pipes, culverts). To avoid conflicts in actions and to capitalize on available funding, coordinated planning that addresses local and regional needs and takes flood risk and uncertainties into consideration are important. Action related to education and engagement are important to understand potential results of planning decisions and to inform the public and decision makers. Research and communication of knowledge between groups (i.e. scientists, planners, community decision-makers and members)

[4] The National Flood Insurance Program's (NFIP) Community Rating System (CRS) is a voluntary incentive program that recognizes and encourages community floodplain management activities that exceed min. NFIP requirements. (U.S. Climate Resilience Toolkit)

is needed to bridge actions and must work across scales.

3.3. Knowledge

In order to communicate science to officials and the public, understanding change – what is changing and how – is essential. It is equally important that the science addresses the range of problems relevant to the community so that decision-makers can balance likely trade-offs. Science-related knowledge includes enhancing understanding of the temporal dynamics of floodplains, enhancing accuracy of watershed data, and contributing to knowledge of future flood projections to communicate uncertainties that can lead to better outcomes and actions. Education for the public and municipalities on the NFIP; mitigation strategies, options and costs; and watershed regulations are all identified as contributing to knowledge. Knowledge of mitigation strategies and best management practices (BMP), – when, where, what -contributes to knowledge for optimizing solutions. Accounting for knowledge must be carefully considered in the context of place and time; BMP for one location may not be ideal for another and today's BMP may not work under future conditions. Knowledge of BMPs that contribute to multiple objectives, such as flood control and water quality, is important. However, these objectives may be in conflict with community desires.[5] There is a need for knowledge related to adaptive strategies that account for future changes and current decision-making (for example, decisions related to structural elevation of houses). Knowledge contributing to understanding and identifying, leveraging and optimizing costs associated with BMPs and implications for property owners is necessary. These costs may include first-costs for design and implementation, but also long-term costs of maintenance. In Selinsgrove, knowledge is needed to inform about flood potential and impacts of local streams and tributaries and implications of upstream agriculture and land use, pre- and post-development conditions on waterway performance and maintenance.

3.4. Values

Values in Selinsgrove focus on two areas: 1) quality of life and 2) economic resilience. Quality of life are expressed in terms of health and well-being of the residents and the health of the local environment. This includes aquatic health, water quality, and preservation of recreational opportunities, particularly river recreation. Aesthetic factors such as protection of historical places and maintaining the charm of the community are also included under the category of well-being. Aesthetic value is equally connected to river towns' historic charm and to the environmental beauty of the area. The Susquehanna River, embedded in the history of Selinsgrove, is seen as key to quality of life for both recreation and natural beauty.

Economic resilience is expressed in the context of both individual and community needs, with a key focus being flood resilience. The emphasis on individual economic resilience concerns protection of property from flooding and creation of job opportunities. Community-wide economic resilience focuses primarily on the economic vitality of the downtown area as a key element of community economic vitality. Strengthening the relationship between the downtown and Susquehanna University is identified as a key component of economic resilience. In general, a thriving downtown, a strong tax base, and protection of property values are identified as economic issues of importance and value.

These two general areas of value are often seen as interdependent. The economic resilience of the downtown area is viewed as directly linked to community well-being. The values related to the health and beauty of the river and

[5] Strategies such as planting trees have potential for multi-objective benefit however conflicts may arise between installations that improve water quality (i.e. riparian buffers) or those that allow for recreational opportunities.

surrounding environment are, in turn, seen as linked to economic resilience since they attract residents as well as visitors. Flood resilience is identified as a key factor in both domains.

CONCLUSION

The workshop provided an initial forum to focus on flooding and community vitality to better understand the challenges, potential actions, knowledge gaps, and values at play. The thoughts shared by participants highlight the continued need for coordination and communication to address flooding in Selinsgrove and other flood-prone riverine communities. Going forward, focused research and enhanced communication of knowledge between groups (i.e. scientists, planners, community decision-makers and members) is needed. Moving from knowledge to action has the potential to reveal trade-offs, must account for uncertainty, and needs to bridge regulatory and political constraints. How to handle likely trade-offs between values can be a source of conflict but also an opportunity for dialogue, identification of additional knowledge, data and needs, and sound decision-making. Feedback on challenges, values, knowledge and actions will be used to inform and improve decision making processes. The PSIRC team is currently working on a mental model from the perspective of academic researchers that considers relationships between flood and community resilience. During the next phase of this work, community representatives will be interviewed to establish a mental model from the perspective of local experts.

> Comparing the two models helps to identify crucial gaps in understanding – by both groups, and focuses communication and outreach on the most relevant and meaningful information individuals need to make informed decisions. (Bessette et al 2017: p1993-1994).

In the interest of accounting for uncertainty related to climate change and climate risk, values will be embedded into the established Values Informed Mental Model (VIMM) and used as a tool for broader stakeholder engagement. An anticipated outcome of this initiative is to establish decision-support processes to inform a responsive and coordinated portfolio of information as a basis for the community to attract funding and undertake resilience planning and implementation projects.

ACKNOWLEDGEMENTS

Thank you to Casey Helgeson, Lacey Goldberg, Lara Fowler, Klaus Keller, Robert Nicholson, Nastaran Tebyanian, and Nancy Tuana for their input and collaboration. Special recognition to H.W. "Skip" Wieder for convening the workshop in Selinsgrove, PA and soliciting PSIRC's ongoing participation. This work is supported through the Penn State Initiative for Resilient Communities (PSIRC) by a Strategic Plan seed grant from the Penn State Office of the Provost and is being undertaken in partnership with the Center for Climate Risk Management (CLIMA), the Rock Ethics Institute, Penn State Law, and the Hamer Center for Community Design.

PAPER #8.11

BUILDING INDEPENDENCE

Scott Gerald Shall[a]
[a]Lawrence Technological University, Southfield, Michigan

ABSTRACT

During the summer of 2019, a team of eleven students, faculty and professionals with backgrounds in architecture, design and engineering traveled to Port Elizabeth, South Africa, where they partnered with local community members to design and construct an event- and maker-space from scavenged materials. This project was completed by eleven people in ten days, three days scavenging materials and designing and seven days constructing, and with a budget of only $1500 - facts which give the work resonance. To our partners, who live and work within post-apartheid communities of great need, the humble frugality of the project is not a nicety, but an essential attribute. For it is only through such limits that the work is able to shift from a tantalizing one-off that increases the community's dependence on outside support to a physical and inspirational foundation through which they might realize new works for years to come. If successful, this propagation will continue indefinitely, allowing the community to ostensibly rebuild itself using modest means, and without external support.
The presentation proposed by this abstract will describe the process used to create the foundational maker-space, highlight the lessons learned through its execution and offer insight into how this process, and the resulting work, might be refined in the future.

KEYWORDS

Extra-legal communities; socially-responsive design; bricollage; viral propagation.

1. DEFINING EXTRA-LEGAL COMMUNITIES

First, a point of clarification: the architectural approach described by this writing is specifically designed to respond to communities that are often identified through their purported informality (re. informal settlements). However, to classify these settlements as such is misleading, as the communities so identified often have well-defined approaches to land ownership, construction and occupation. They are simply poorly understood, as they exist outside the formalized networks most professionals are trained to serve and, thus, understand. To form a more accurate definition, one might look to the core attributes of these settlements, as offered by organizations like UN-Habitat or the WHO (UN-Habitat, 2015, also WHO, 2000).[1] First, settlements of this type will be located on borrowed land, generally acquired outside the legal framework designed to support land transfer. And second, these settlements will be constructed outside the limits of the formal construction processes, built using unapproved plans and scavenged materials. Although both characteristics vary somewhat between settlements, they both remain inherently linked to the situation of those who occupy this settlement type – settlers who are coming to the settlement under some degree of duress, with scarce resources with which to reestablish their lives within a new location – and are thus universal within this settlement type. To operate well in these extra-legal settlements, requires that architects, engineers and other professionals align their approach with these realities, in four ways (Shall, 2018).

[1]The definition for informal settlement offered by the UN-Habitat Programme, which is arguably the definition most widely applicable, includes only two primary characteristics: informal settlements are illegally located and they are illegally constructed. It naturally follows that, now and in the future, most settlements will be extra-legal. (UN-Habitat, 2015, 3)

1.1. Tenant One: Borrowed Land

The first tenant is linked to the fact that the occupants of extra-legal settlements do not have the means, nor need, to create their built environment using formal networks. The first supposition - the lack of means - requires little elaboration, as it is the chief motivating factor behind the occupants establishing their lives within this setting. The second supposition – that the occupants do not have the need to submit to the formally established processes - is linked to the fact that these developments are rarely fully defined, mapped or understood by the governing authorities (Thieme & Eszter, 2015).[2] They fly under the radar. This is, ironically, due to the fact that these settlements are generally quite large and grow very quickly - characteristics which prevent the governing authorities to define, map or even exert influence over these settlements (Thieme and Kovacs, 2015).[3] They are thus largely ignored, at least until a new development opportunity, safety concern, international scrutiny or other important event demands some measure of attention. The fact that these settlements will hide in the open, with rare, albeit intense, punctuations of unanticipated scrutiny and intervention, has a significant impact upon the architecture. In this settlement type, elements that only have value when stability of placement is ensured, such as foundations, massive construction types, or robust attachments to engineered infrastructures, are of less value than those that are transportable or inexpensive. This promotes the creation of architecture that is light, inexpensive, and without any undue investment in concerns that are permanently tethered to place.

1.2. Tenant Two: Scavenged Materials

The second tenant share a root with the first. That is, in shifting from an architecture anchored to place toward lightweight, inexpensive structures that address immediate need, the residents minimize the need for professionals to help design verifiable or complex structures and opens up the possibility of an architecture that is constructed almost entirely of scavenged materials using only simple tools and easily-learned techniques. This allows the occupants of extra-legal settlements to eschew materials such as of concrete and glass for much more accessible materials like tarps, corrugated metal, recycled plastic, straw, wood scrap and the occasional concrete block (Davis, 2006). Correspondingly, instead of building using well-studied and highly calculated joinery, as required by concrete, glass or steel construction, the extra-legal settlement favors joints that use more common techniques, such as wrapping, tying, or stacking. The resulting joints rarely require expert training to execute or specific pieces of hardware. Rather, the built work prioritizes connections that can be realized using whatever is at hand. This aligns the processes of construction, and the resulting tectonic, with the approaches favored by the bricolleur, not the architect or engineer – a point that will be made clear later in the writing.

1.3. Tenant Three: Social Capital

The third tenant naturally follows the first two: after all, if one is realizing a settlement using common tools and easily understood methods of construction instead of those requiring more expensive and less accessible tools and methods, then one is ostensibly trading techniques of construction requiring cranes, excavators, and other large-scale

[2]The implication has been that informal economic activities and by extension informal provision of goods and services were not only described as irregular, casual and potential precarious, but also outside the remit of state regulation and surveillance. Therefore, as urban slums are characterized by informality in all spheres of life, they become to an extent invisible to the state, especially in terms of public provisions." (Thieme & Kovacs, 2015, 18)

[3]In the shadows of rapid urbanization and economic liberalization across the world, the formation and demographic growth of informal settlements or 'slums' far outpaces the availability and capacity of urban planning." (Thieme & Kovacs, 2015, 1)

supports for those able to be realized through the infusion of more people. After all, one of the chief assets of simple tools and easily-understood methods of construction is their transferability. This asset, when married with the immense size and rapid growth of this settlement type, causes the residents of extra-legal settlements, and thus the settlements themselves, to align their value systems with physical capital first, then social capital, instead of economic or symbolic (Thieme and Kovacs, 2015).[4] Rather than purchase commodities, residents will often trade or barter; instead of accruing status (although this does occur once residents establish themselves), residents accrue associations and allies. This shift impacts the priorities of the built environment, emphasizing the ability to help generate social capital, instead of cultural.

1.4. Tenant Four: Viral Propagation

The fourth tenant is distinct in that it is not based upon the needs of a single occupant for a particular architectural approach, as was the case with the other three, but upon an architectural asset derived from the nature of the first three realignments. Specifically, the need to create lightweight, inexpensive architecture on land illegally acquired using borrowed materials, common tools and easily-understood methods creates a design approach that is perfectly situated to promote the rapid propagation of the settlement itself. This asset has, over time, become a core defining characteristic of the settlement itself, allowing the extra-legal settlement to grow at a rate that far outpaces the speed at which their legal counterparts are generated (UN-Habitat, 2013).[5] The rapidity of their expansion has also rendered obsolete the methods of design and construction favored by the architect, engineer and other supporters of more formalized networks. The scale of this growth, although problematic when propagating poorly conceived or unsafe architecture, this becomes a potential asset if well-formed architecture could be aligned so as to benefit from this rapid propagation network.

2. SHIFTING ARCHITECTURE TO SUPPORT EXTRA-LEGAL SETTLEMENTS

2.1. Movement One: Becoming Socially-Responsive Outsiders

The extra-legal settlement, thus understood, creates an obvious set of challenges for those professionals who wish to engage the residents of this unique community. The first challenge is associated with the fact that the extra-legal settlement is a natural by-product of the legal settlement – an unavoidable remainder created by the abuses of powerful actors who benefit most from the formalized system. The fact that these powerful actors have, historically, enlisted the talents of architects, engineers and other professionals to extend their influence and solidify their favored position, creates a difficulty whenever these professionals attempt to offer their talents to those living within extra-legal settlements (Crawford, 1991).[6] Much of the reason for this can be traced to the educational and professional structures used by these professionals, which have, over time, been calibrated to support one system at the expense of the other. The professionals, so

[4] "...what ties the rural and urban slum experience in relation to the nexus are the prevalence of social networks and social capital as the dominant albeit informal platform for self-organizing and provisioning that determine how things get done." (Thieme & Kovacs, 2015, 11)

[5] Informal settlements represent the largest and fastest growing urban condition on the planet. In fact, according to a 2012 UN-Habitat report, "since 1990, 213 million slum dwellers have been added to the global population." (UN-Habitat, 2012)

[6] "By distancing themselves from contractors and builders with economic control of the field, they (architects) also effectively repudiated the interests of moderate-income clients. Instead, the profession linked its professional identity to large-scale monumental commissions requiring wealthy patrons. This left architects dependent on the restricted group of clients who could afford to support their ambitions: the hoped for, but only occasionally awarded, patronage of the state (far less active than in Europe), but more often, the backing of large business and corporate interests." (Crawford, 1991, 30)

indoctrinated, become an extension of this unjust order (Shall, 2018).

It is important to acknowledge that this association persist whether or not it is acknowledged by the professional (Freire, 2010).[7] In fact, non-acknowledgement can create a naivety that is easily exploited by those who have historically benefited from the work of these professionals, as evidenced by the ways in which new work offered by these professional can fail to meet the needs of those residing within extra-legal settlements. The first failure type is linked to the importation of highly-engineered solutions from external contexts, without regard for localized conditions (UN-Habitat, 2015).[8] This prevents the offered solution, despite the fact that it is arguably well- designed for its stated purpose, from ever finding root in the community. This lack of anchoring can cause the community to reject the project. This rejection might assume the form of anything from indifference to the outright consumption of its offered assets in order to support better understood constructions (Thieme and Kovacs, 2015).[9] The second failure type is slightly more insidious, as it involves the purposeful shifting of resources dedicated to help extra-legal settlements to wealthier communities. Author Mike Davis terms this activity "poaching" and attributes it to the extra-legal settlement's lack of political influence, noting that "a consensus of urban scholars agrees that public- and state-assisted housing in the Third World has primarily benefitted the urban middle class and elites" (Davis, 2006).[10]

To address this inherent bias, requires that the design professional acknowledge this professional bias and then seek to create approaches that reverse the flows of knowledge and expertise. Instead of imposing highly-engineered solutions, optimized using imported values and quantifiable data sets, the designer must work with the residents of extra-legal settlements to understand the values and resources that are already present and then collaboratively evolve these assets in order to supporting a more sustainable, but perhaps less optimized, means of distributing assets like water, shelter, energy, education,

Figure 1. The Community Makerspace in Port Elizabeth, South Africa was constructed almost entirely of reclaimed materials, at a cost of $1500 in under 7 days by a team of 11 (Shall 2019).

[7]"It happens, however, that as they cease to be exploiters or indifferent spectators or simply the heirs of exploitation and move to the side of the exploited, they almost always bring with them the marks of their origin: their prejudices and their deformations, which include a lack of confidence in the people's ability to think, to want, and to know ...They talk about the people, but they do not trust them; and trusting the people is the indispensable precondition for revolutionary change. A real humanist can be identified more by his trust in the people, which engages him in their struggle, than by a thousand actions in their favor without that trust." (Freire, 2010, 61, emphasis mine)

[8]"Many upgrading approaches continue to inappropriately import solutions from other places without adapting operations to the local context. They are therefore unable to neither take full advantage of local knowledge nor develop city-wide /'at-scale' responses." (UN-Habitat, 2015, 3, emphasis mine)

[9]"Particularly when it comes to basic service provision, a form of 'malevolent urbanism' has generated across urban areas in the global South, where unequal access to and use of the city is prevalent. At the same time, a mosaic of actors, sectors, and initiatives seek to address the 'challenges of slums', usually purporting to work with local communities, but often misunderstanding how everyday practices and expectations might differ from externally defined development goals and impact measures." (Thieme & Kovacs, 2015, 1, emphasis mine)

[10]"Both 'poaching' and fiscal bias, of course, are expressions of the poor majority's lack of political clout throughout most of the Third World; urban democracy is still the exception rather than the rule, especially in Africa. ... A consensus of urban scholars agrees that public- and state-assisted housing in the Third World has primarily benefitted the urban middle class and elites, who expect to pay low taxes while receiving high levels of municipal services. (Davis, 2006, 68-9, emphasis mine)

medicine and information (Thieme and Kovacs, 2015).[11] Provided that this evolution – from localized conditions and understanding to sustainable address – are generated collaboratively, then the offered design will likely become an extension of local assets, leading to its adoption by the host community. Although requiring a constant, and sometimes uncomfortable, examination of professional and methodological bias, this tactics is quite effective, allowing the professional to put aside the mantle of either insider – which will never be an accurate description of their role or status – or outsider – which will only perpetuate the problems described above – in favor of becoming a responsible outsider (Freire, 2010).

To illustrate how this movement, as well as subsequent movements offered by this writing, might manifest within an architectural work, one might consider a small project recently completed in Port Elizabeth, South Africa. In this work, a small team of students, faculty and professionals partnered with local, South African community members to design and construct an event- and maker-space from scavenged materials. To realize the now-completed work in only ten days, the team had to focus our efforts on only those matters pertinent to our expertise and perspective. This required the team to first build a body of trusted, local experts who could supply much of the insight required to execute this project and then listen carefully to their perspectives and beliefs. Fortunately, internet-based communication tools allowed for this process to occur well before the team even departed. This allowed them to test, remotely, the judgments and perspectives of their partners against other points of view. Through this process, the team grew to trust their assembled body of local experts, and the experts, the visiting team. The team was also able to understand more clearly the situations in which their partners' knowledge was well-formed, requiring no elaboration from them, and where they might offer useful support. This created a dialogue through which all parties were able to understand which project parameters the visiting team should consider as controls and which were variable, open for development. Areas in which the local partners had deep experience – the choice of a particular site, the specific program requirements for the development, the initial inventory of materials and the core partnerships that would energize the project – were thus taken as accurate and assumed to be givens. Areas in in which these partners needed external experts to responsibly leverage their standing as outsiders to benefit the work

– which materials in the inventory had greatest value to the realization of the work, how the inventory might be evolved to better support the work, additional materials and supports that might help us to realize the work

– were viewed as variables, becoming the focus of the visiting team's design energies.

2.2. Movement Two: Learning How to Practice as Bricolleur-Designers

The second shift required of the professional is based upon the aforementioned priority given to scavenged materials in the construction of extra-legal settlements. Here, instead of designing based upon an assumed set of ever-available materials, those operating in these settlements base their craftwork upon the idiosyncratic nature of whatever is at hand – a mandate that aligns the architect's approach more with the bricolleur than the engineer. The bricolleur, as distinct from the engineer who requires an inventory of pre-determined materials of well-known and highly specifiable attributes, operates with an ever-changing inventory of assets. Identified as a 'devious craftsman' by Claude Levi-Strauss, the bricolleur is able to perform a large number of tasks within a closed set of assets, much of

[11] Theime and Kovacs also urge those attempting to positively impact the conditions found within slums to reverse the "flows of knowledge and expertise so as to theorize the nexus from the slum, where inhabitants experience everyday relationships to water, food, energy and waste as integrated." (Thieme & Kovacs, 2015, 15, emphasis mine)

which will have been created from the remains of already completed acts of construction or destruction, instead of the demands of the current work (Strauss, 1968).[12] This aligns well with the manner in which extra-legal settlements are built and re-built – activities that are always completed using a stash of pre-gathered materials, the vast majority of which have limited pre-determined utility aside from broad notions of being inexpensive, lightweight, water-tight or durable. In this place, the chief task of the designer is to maximize the utility and expression of this finite set of resources. Massing and form, often foundational concerns within acts of architecture and engineering (due to need to maximize real estate valuations, capacities, and other quantitative attributes) must become subordinate, adjustable to the means at hand. Aside from limits that are determined in a broad sense based upon the available site (which is also a scavenged resource), the form of the work subordinates itself to the closed set of materials and whatever structural componentry one might find therein – components which forms a rare, and thus valuable, subset of objects within the stash. Similarly, program activities, another foundational attribute to the classically trained architect, must respond to the finite set of scavenged materials, shifting their placement and nature in accordance to the confines of this fixed resource. Even the tectonic of the work assumes a reactionary role, forged not from an assumed set of highly predictable and specifiable means but from highly idiosyncratic kit of of parts accumulated without knowledge of the project at hand (Strauss, 1968).[13]

This is not to state that ideas of form, massing, program and tectonic bear no influence upon the stash. Only that these values must find their expression within this finite assembly. Instead of dictating what is in the stash, ideas of form, massing, program and tectonic work to form a hierarchy of value within the previously heterarchical stash of materials. This valuation becomes a core task of the architect operating in the extra-legal settlement: to identify those components within the stash that bear rare attributes of immediate and fundamental value to the architecture, such as the ability to support weight, span distances without deflection, or provide an unbroken envelop, and

Figure 2. Purlin joint and mechanism for the sliding walls from reclaimed stock (Shall 2019).

[12]"The 'bricoleur' is adept at performing a large number of diverse tasks; but, unlike the engineer, he does not subordinate each of them to the availability of raw materials and tools conceived and procured for the purpose of the project. His universe of instruments is closed and the rules of his game are always to make do with 'whatever is at hand', that is to say with a set of tools and materials which is always finite and is also heterogeneous because what it contains bears no relation to the current project, or indeed any particular project, but is the contingent result of all the occasions there have been to renew or enrich the stock or to maintain it with the remains of previous constructions or destructions. The set of the 'bricoleur's' means cannot therefore be defined in terms of a project (which would presuppose besides, that, as in the case of the engineer, there were, at least in theory, as many sets of tools and materials or 'instrument sets', as there are different kinds of projects). It is to be defined only by its potential use or, putting this another way and in the language of the 'bricoleur' himself, because elements are collected or retained on the principle that 'they may always come in handy'. (Levi-Strauss, 1968, 17-8)

[13]"It might be said that the engineer questions the universe, while the 'bricoleur' addresses himself to the collection of oddments left over from human endeavors, that is, only a subset of culture." (Levi-Strauss, 1968, 19)

then to develop a design approach, manifest in form, massing, tectonic, and program, based upon these now valued assets. This architect then continues this process until all such foundational needs are met, at which point materials of lesser value - both in terms of the stash and wider community - are deployed to the greatest extent possible, so that more universally valued materials and components might remain in the stash for future projects (Strauss, 1968).[14] This shifts the influence of the design from larger-scale concerns to smaller, more subtle concerns that are able to elevate the utility and expression of the stash. Details, although required to be formed from common, readily-available tools so as to allow for propagation, thus become the focus of the design exercise. This tact, aside from supporting the obvious financial need for modesty, encourages an environmentally-sound approach to designing wherein the most complex and sizable materials are reclaimed and only the more minor components are modified, new or purchased.

One final component of the stash bears mention due to its unique influence upon the design. Often, when accumulating the stash, the bricolleur, or the bricolleur's partners in the case of many works within extra-legal settlements, will not only highly value components offering immediate and obvious value (structure and durability), but also to materials of unique, utilitarian character. Components offering industrially-produced simple machines – pulleys, levers, bearings, and other simple machines - are a clear example, as they allow future work to potentially align with fundamentals of physics without needing to creating complex items. Thus it is often the case that the stash of materials will include quite a few of these simple, industrially-produced machines. Although these idiosyncratic elements will often require a great deal of evolution in order to be of value to the project, they remain of unquestioned value, and thus bear a significant imprint upon the design approach.

To execute the work in South Africa within the given confines of the project - $1500, 11 people, 10 days – required that the team regard the materials already gathered to support the project as a finite set and function as bricolleur-designers. As such, the team's first act in the city was to learn everything they were able to about these materials. Every scrap was photographed, dimensioned and modeled in both Revit and Rhino. The team then tested this inventory of parts and brought this information to bear upon the knowns of the project itself: the dimensions and orientation of the site, the required turning radius for trucks delivering containers for future developments, and the absolute minimum acceptable parameters for the programmed spaces. The fact that the work had to be realized using only the given stash of materials – a stash that only contained so many items of any value to structural cladding concerns - greatly limited the set of potential formal approaches to the project, resulting in the relatively quick resolution of the overall massing of the work and allowing the visiting team to focus greater energies upon detailing the work in a manner that would maximize the value and effectiveness of the assembled parts. It was here that the group turned to precedents provided by architects operating in more formal settings. For example, the joinery of Thorncrown Chapel provided the team an approach to design that permitted them to use shorter purlins for the roof and the pivoting details of Tom Kundig, a method to allow a small footprint to support larger crowds and constructions. It is important to note that this last set of details, which required massive elements of the architecture to slide or pivot, were only possible because the local partners in the work had gathered axles from drivetrains and other unique elements, "just in case."

[14]"The elements which the 'bricoleur' collects and uses are 'pre-constrained' like the constitutive units of myth, the possible combinations of which are restricted … the decision as to what to put in each place also depends on the possibility of putting a different element there instead, so that each choice which is made will involve a complete reorganization of the structure." (Strauss, 1968, 19)

Figure 3. Constructing the mechanism for the rotating walls using scavenged bearings (Shall 2019).

2.3. Movement Three: Emphasizing the Generation of Social Capital

As earlier indicated, the architecture of extra-legal settlements, crafted in a context of scarce resources, with scavenged materials, common tools and simple techniques, naturally privileges social capital over economic capital or symbolic capital. Thus, to thrive here, the built environment must not rely upon economic capital for sustenance or growth. After all, these are settlements whose entire identity is founded upon a lack of economic resources and whose disadvantaged position is reinforced at key moments through clearing and other legitimate acts of physical force. This state of affairs somewhat distances the concerns of those residing within the extra-legal settlement from the cultural norms of the inverse cityscape, a value structure that directly led to their position of subservience, which, in turn, causes those residing therein to view these values with skepticism or outright disdain (Stevens, 1998).[15] Not surprisingly, this perspective can also cause residents to view engineers and architects, professionals who support the aforementioned cityscape through the creation of cultural capital, with a similar degree of negativity.

Instead, the residents of extra-legal settlements prioritize social capital, because it aligns more directly with the chief assets held by the residents and their built environment: namely, scale and replicability (Thieme and Kovacs, 2015).[16] That is, although the residents of extra-legal settlements have limited economic means, very little access to legitimate physical means, and only passing interest in symbolic structures, they have numbers – quickly growing numbers – and a unifying cause defined by their need to survive within a context stacked against them (UN-Habitat, 2012).[17] It is, thus, through social capital that the residents of extra-legal settlements might leverage their quickly growing numbers to overcome their lack of other resources to help ensure the survival of the settlements themselves, which are often too large for cities to easily eradicate, and improve living conditions.

The architecture can support this shift in several ways. First, the design can be articulated in a manner that leverages the fact that the built work is based upon simple construction techniques and common tools in order to expand the body of contributors. As earlier stated, the built environment of the extra-legal settlement is not the product of unique or exclusive means – a situation that would inherently limit the contributors to a very small set of professionals and force

[15] "For Bourdieu, power is the capacity to impose a specific definition of reality that is disadvantageous to others. The most obvious sort of power is physical force, but only a few groups use physical force. It is inefficient, and most societies grant the monopoly on the use of legitimate physical violence to the state. A second type of power is economic. The importance of this is obvious. Marxian theory holds that economic power is the only sort of power, and that all groups can be placed in some sort of social hierarchy, their places contingent on the amount of economic capital they control. One of of Bourdieu's major contributions to modern sociological theory has been to extend Max Weber's sociologizing and decisively demonstrate that this is not so, that there is a third, more potent and pervasive form of power – the symbolic. Symbolic power involves the wielding of symbols and concepts, ideas and beliefs, to achieve ends. "At the highest level, that of society as a whole, we call the field in which symbolic power operates 'culture'. It is Bourdieu's contention that the logic of the cultural field is such that is operates to create, legitimate and reproduce the class structure, a system of inequality." (Stevens, 1998, 59)

[16] "...what ties the rural and urban slum experience in relation to the nexus are the prevalence of social networks and social capital as the dominant albeit informal platform for self-organizing and provisioning that determine how things get done." (Thieme & Kovacs, 2015, 11)

[17] "Physical upgrading of slums with street networks and improved access to municipal basic services through augmentation of physical infrastructure has proven to make formidable positive social and economic changes in many cities. Socially, upgraded slums improve the physical living conditions, improve the general well-being of communities, strengthen local social and cultural capital networks, the livelihood generation opportunities, quality of life, and access to services and opportunities in towns and cities." (UN-Habitat, 2012, emphasis mine)

the community into a position of passively accepting (or rejecting) the offered solution. Instead, it is the potential product of the many hands, which not only allows the work to be executed more quickly and with less individual effort, but increases the community's vestment in the work and thereby generates greater connection between the individual members of the settlement. Collaborative construction generates social capital. And, provided that the means and materials remain accessible, the generation of social capital can continue for as long as the community seeks to expand or develop, potentially allowing the architecture's "liberating intention" to align with "the real practice of people in the exercise of their freedom" (Foucault, 2002).

Although the first year's work in South Africa relied more heavily upon the energies of the external team than will be the case in future years, as the project generates more social capital, there exist several examples of how the schools, clinics and other projects that come from this initial effort might be able to borrow from this work to generate greater participation, and social vestment. The first example was accidentally uncovered and is the result of the team not questioning the internal body of experts appropriately. Specifically, to dig the trenches for the foundation, the local body of contributors had used their extensive connections to the community to arrange for a backhoe. Unfortunately, the backhoe did not arrive the first day we had intended to excavate, as promised. Nor the second. Finally, on the third day, the team elected to dig the foundations by hand. The backhoe arrived the next day. Although the foundation remains a likely rare moment mandating some degree of external support (i.e. the concrete truck), this situation served to underscore an important point: namely, how important it is to replace rare, complex or expensive tools with simple tools and people whenever possible, in order to create a self-sufficient process and maximize the opportunities for the engagement of many. The second instance of the offered work supporting the generation of social capital is the fact that the most complex joinery and rarest components are reserved for operable walls – elements specifically designed to permit the inclusion of greater crowds in the work. Although this may, if replicated, become an instance of the architecture demanding unique tools or more skilled construction personnel (instances the design worked hard to minimize), this cost was deemed as a smart investment, as it will encourage greater participation, thus becoming an instance of the demands of social capital usurping the limits of the physical.

2.4. Movement Four: Building Toward Viral Propagation

The final movement is a culmination of the first three and is perhaps, the most essential attribute required of the architecture to ensure long-term sustainability. Within this community – a settlement that is propagating more quickly than formal structures can even map, let alone impact - the offered architecture must encourage its own propagation using the networks of exchange that already exist. Specifically, the residents surrounding the work must want to continually understand, borrow, and evolve the design approaches unearthed through the process of generating it. To accomplish this, the architect of extra-legal settlements must marry the three attributes earlier described – dialogical processes, accessible means and participatory construction – with two more attributes.

First, the architecture must be designed in a manner that allows for its simple dissemination to a wide audience using existing information exchange networks. This requires that architect break down the essential insights uncovered through design and construction process into memes: easily exchanged units of information able to flow through existing networks of information exchange within the community, through which residents learn key survival techniques, including how to

hijack electricity, find clean water or avoid the unwanted attention of the authorities. Properly articulation, this not only allows for easy transmissions, but permits the work to disseminate key points without using top-down project dissemination, which are both too slow to keep pace with the rapid growth of these settlements and assume a paternalistic hierarchy of knowledge transference. Through the meme, the architect's work moves from the creation of objects to the creation of objects of knowledge – material constructs that collect the wisdom of many and propagate virally (Shall, 2013).

Second, the architecture must allow for this now-expanded body of contributors to independently offer their ideas and simultaneously explore alternatives – a process that occurs quite often in the world of business. To illustrate, at the birth of a new technology (the automobile, the television, the Internet) there is often a rapid expansion in the number of businesses that grow around the promise of these technologies. Far more businesses than can succeed fight for supremacy, each attempting to offer the best product to the consumer. Over time, the consumer, through their acquisition of the offered product, judges some ideas to be better than others. As businesses respond to these trends, a Darwinian shift in investment emerges, until a much smaller set of products have each found a niche within the market (Surowiecki, 2005). Within the extra-legal settlement, this evolution would occur through the adoption of techniques and tectonics. Approaches that work well – joints that are simply executed, inexpensive materials that are easily acquired, or efficient construction approaches – would be quickly adopted, while ideas less efficacious would be ignored. Over time, this process would hone the design approach to such a degree that the new work, which would be generated entirely by the community, would far out-perform the offered architectural approach that instigated the entire process, created an effective architectural response hardwired to the conditions of the community (Shall, 2019).

Returning to the work in South Africa, although the illustrations for this fourth point will become clearer over time, there are already several indications that the propagation of the original work is already taking place. First, the interest created by the first installation has already resulted in the local partners receiving offers of new sites for development, new materials for construction and new sources of financial support. Second, the details from this first installation have already begun to appear in other plans and installations. This despite the fact that the installations in years two and three of the project will feature simpler means and more common materials. For example, the glue-lam beams created by the visiting team from reclaimed wood, despite being an effective use of scavenged materials, will likely be replaced in future projects in favor of simpler techniques that are more easily understood and evolved. Third, and perhaps most importantly, the number of potential collaborators in Port Elizabeth, and South Africa, has greatly increased due to the efforts of local partners and the successes realized by the first work. This will allow subsequent visiting teams to be matched with an equal number of experts from the community itself. More importantly, as the work continues to advance, the number of local collaborators will as well, until local residents are the primary support for the advancement of the work and the presence of a visiting team is no longer required. Instead of increased dependency, the architecture generates a healthy, self-sustaining structure of support – the type of structure that is required if the work of architects intend to increase access to food, water, medicine or education within extra-legal communities.

PAPER #8.12

THE ISSUE WITH INCLUSIVITY: THE PROMOTION OF EQUALITY AND DIVERSITY WITHIN ARCHITECTURAL EDUCATION

Isabel Deakin[a]
[a]Mackintosh School of Architecture, Glasgow School of Art, Glasgow, Scotland, UK

ABSTRACT

How can architectural education become more inclusive to facilitate the development of equality and diversity within the architecture profession and the built environment?
The Equalities Act came into force within the UK in 2010 and is designed to legally protect people from discrimination in the workplace and in wider society. There are 9 protected characteristics identified within the act which are: age, disability, gender reassignment, race, religion/ belief, sex, sexual orientation, marriage and civil partnership, pregnancy and maternity. This paper investigates inequalities in relation to these characteristics and how they manifest themselves within architectural education, the practice of architecture and the built environment.
I argue that the current lack of equality and diversity within the profession and within the practice of architecture is directly linked to the lack of inclusivity within architectural education and that if inclusivity is promoted within the education process it will improve equality and diversity in architecture as a whole.
This paper describes an Action Research Project which was undertaken as a result of identifying that within architectural education what we teach, how we teach and who we teach needs to be more inclusive. It discusses the what: curriculum, the how: teaching methods and the who: the students and hypothesizes that these three areas currently do not support the diversity of the future generation of architects or wider society.
Through a mixed methods approach, this study explored the attitudes and experiences of architecture students at both undergraduate and post graduate level from one School of Architecture. Participants took part in a questionnaire, interactive on line discussion board, participatory workshop and focus group where they explored issues around inclusivity, equality and diversity.
The findings demonstrate there is a desire to engage in issues of inclusivity, diversity and equality within the wider architectural curriculum and suggests a variety of strategies to support a more inclusive approach to architectural education.

KEYWORDS

Architecture; inclusive design; equality; diversity

INTRODUCTION

Within the Royal Institute of British Architects, RIBA, Strategic Plan 2016-2020, which outlines the focus and priorities for the RIBA, it states

> Our Purpose: To serve member and society in order to deliver better buildings and places, stronger communities and a sustainable environment.
> Our Values: Being inclusive, ethical, environmentally aware and collaborative underpin these strategic objectives and all we do. (RIBA, Advancing Architecture, Strategic Plan 2016-2020 2016)

It further states within its strategy 1.2 that to achieve this it will:

> Attract and retain the best and most diverse talent:
> Engage school-age students to inspire an interest in architecture
> Work with schools of architecture and practices to engage the next generation of architects in the future of the profession
> Support our members and Chartered Practices in overcoming the barriers to an inclusive profession. (RIBA, Advancing Architecture, Strategic Plan 2016-2020 2016)

And yet in 2019 the RIBA Graduate Attributes for Part 1 and Part 2 do not mention inclusivity or inclusive design and within the curricula published on line for all the Schools of Architecture in Scotland, there is no mention of inclusivity or inclusive design. Furthermore, it is recognized that there is a lack of diversity within the teaching staff within Schools of Architecture across the UK as highlighted in academic data from 2014-2015 where 70% of faculty staff were male and yet 45.4% of students were female. (Morrow 2016)
As Weisman reflects in her article 'Diversity by Design: Feminist Reflections on the Future of Architectural Education and Practice'

> How can an architectural education that continues to define professional expertise in relation to the history of white, heterosexual, Euro-American male consciousness prepare students to function as effective professionals in pluralistic communities? How will students be sensitized to "difference" when they are encouraged to suppress their own gender, race, and class identities in the process of becoming "professional"? (Brown 2016, 1)

The following areas for improvement have been identified:

- Increased opportunities for students to engage with issues of diversity and equality within the curriculum
- More challenges to design inclusively within the studio environment especially with regards to the diversity of the end users
- Development of teaching methods to support diverse learning methods which take into account the varying needs of the student cohort

If we agree that equality and diversity should be part of architectural education, the question remains how can schools of architecture become more inclusive and will this facilitate the promotion of equality and diversity within architecture as a whole?

1. CONTEXT

The problems of diversity and equality within the architecture profession are well documented by amongst others Despina Stratigakos in 'Where Are the Women Architect's' (Stratisgakos 2016) and Dr Harriet Harris et al, in 'The Gendered Profession – the Question of Representation in Space Making' (Morrow 2016). Equally The annual 'Women in Architecture' survey in the UK shows that issues of equality within the profession are getting worse with the gender pay gap widening at top level practices, 1 in 7 women architects experiencing sexual harassment and 9 out of 10 women stating that children hinder their careers. (ArchitectsJournal 2018)
If you then consider this discrimination along with other protected characteristics identified within the Equalities Act of 2010, it is concerning how exclusive architecture as a profession still is and the question remains why this is not being tackled within the education process. There is however far less documentation on the inequalities within the architectural education process and more specifically the curriculum and the ways of teaching architecture.
Morrow highlights this in her essay 'Architectural assumption and environmental discrimination: The case for more inclusive design in schools of Architecture' (Nicol 2000, 43-48) which draws on the DraWare

research project at the School of Architecture, University College Dublin, and suggests ways of making the curricula more inclusive.
It seems imperative that architectural education should be teaching inclusive design as a way to foster inclusion within the built environment as a whole. However, as Larkin highlights

> Despite this global shift in attitudes and policy in recent years, it is yet to transfer to a major shift in the education program of architects and designers. (Larkin 2016, 19)

This is further highlighted by the lack of inclusivity discussed within the RIBA Part 1 and Part 2 Graduate attributes (RIBA, Validations Criteria - Royal Institute of British Architects 2014) and within the curricula of many Schools of Architecture.
It can be argued that until the emphasis shifts within Schools from the desire to create intellectual and aesthetically pleasing architecture but to also include architecture that is fit for purpose and inclusive for all then we will not be able to tackle the inequalities that currently exist within the profession. Morrow agrees by stating

> Preoccupation with the new, the exotic, and the need to perform what Frampton (1991) calls 'acrobatic feats', are prevalent in the design studio and exist at the cost of everyday issues. (Nicol 2000, 47)

A simple approach to develop a more inclusive architecture within education would be to include within design briefs the need for their outputs to be inclusively designed. This often implicit but never explicit requirement would further strengthen the need for consideration and empathy for the diversity of the end users.
I identify Inclusive Design as the design of places and spaces that support the dignified access to and use for all as identified within the Equalities Act of 2010.

This definition builds on the description of inclusive design set out by CABE (the Commission for Architecture and the Built Environment) which states

> Inclusive design is about making places everyone can use. Inclusive Design aims to remove the barriers that create undue effort and separation. It enables everyone to participate equally, confidently and independently in everyday activities. (CABE 2006)

The question remains, if we encourage students to design with equality and diversity in mind, through the requirement to design inclusively within studio briefs, will this improve levels of inclusivity within the built environment in the future? Surely it's worth trying.
If we then also consider the traditional architectural modes of teaching centred on the master and student relationship to be in need of review to allow for a more inclusive learning environment, what could a new teaching model look like?
The 6 principles for a feminist pedagogy in the teaching of research methods set out by Webb et al (2004), are:

- Reformulating the professor – student relationship (from hierarchy to equality and sharing)
- Ensuring empowerment (for a participatory democracy)
- Building community (through collaborative learning)
- Privileging the individual voice (not only the lecturer's)
- Respecting diversity of personal experience (rooted for example in gender, race, ethnicity, class, sexual preference)
- Challenging traditional views (eg. The sociology of knowledge) (Cohen 2007)

These 6 principles provide a basis for an inclusive style of teaching that responds

to the increasing diversity of our student cohort. I experimented with these principles within the framework of the Action Research Project and analysed and reflected on the success of this different approach. Also by choosing an Action Research Project, it has allowed further feminist research approaches to be undertaken, namely giving power to the participants, through the use of an engagement tool and by conducting long 'interviews' through the workshops and focus groups to allow all voices to be heard. (Cohen 2007)

2. DESCRIPTION AND OUTLINE OF RESEARCH

The structure of the Action Research Project was developed to provide a broad range of data that focused on equality and diversity within architecture but also tested different teaching modes and as such a variety of methods were used. These are outlined in time order as:

- Briefing session
- On line anonymous questionnaire
- On line interactive discussion board – padlet page (anonymous uploads)
- Workshop 1 – 4 first year students
- Workshop 2 – 3 fourth year students and 4 fifth year students
- Focus group/ De Briefing session

3. PARTICIPANTS

Architecture students at both Undergraduate and Postgraduate level were invited to take part. Of the twelve participants who consented to take part and completed the on line questionnaire, 5 identified as male and 7 identified as female. 8 out of 12 self-identified as a protected character as defined by the Equalities Act of 2010 and 4 of these identified in more than one category. The almost equal number of male and females taking part in the study shows that it is not a gendered subject of interest but the high proportion of participants that identified as being part of a protected group I believe shows that first-hand experience plays a part in the interest of inclusivity, equality and diversity.

4. DATA COLLECTION

On-line Questionnaire

The on-line questionnaire which was completed by all 12 participants was designed to give a better understanding of the current knowledge, interest and experience of the students with regards to designing with equality and diversity in mind, inclusive design and inclusive teaching.

Questionnaire: Analysis and Findings

> "I think the most important skill as an inclusive designer, is the ability of reaching out, listening and understanding the needs of different user groups. Sure there are design legislations to aid in particular mobility impaired users but the field of inclusive design expands to other user groups as well. No one and no design device can be taken for granted. At no point in my time in education here I have been taught about the subject." (Questionnaire 2019)

Through analysis of the questionnaire it became clear that all had a sound understanding of what the definition of inclusive design was although it became apparent that the participants from the post graduate level had not worked on any projects that focused on inclusive design. This was different for the first year students who had been exposed to designing for people with disabilities in their very first project. As such the majority of students had developed their knowledge through either the staff run 'Missing in Architecture' lecture series titled 'Peripheral Visions' which invited guests

to talk about subjects on the periphery of architecture or through personal projects and peer discussions. In turn this resulted in the majority of participants (7 out of 12) feeling unconfident about being inclusive designers.

When considering the skills needed to be an inclusive designer there was a recognition that empathy, compassion and understanding were required although it was questioned whether this could be taught or whether this was inherent.

It was felt by the majority of the participants that inclusive design skills were either not taught at all, or could be taught better within the school (7 out of 12). The participants who felt these skills were taught well within studio were all in first year. I believe that this directly relates to the briefs set within first year where there was an emphasis on compassion, client and difference. It is understandable that through the explicit nature of the studio briefs these skills were seen to be developing and were able to be taught. This in turn support the assumption that through teaching inclusive design at University, it will promote inclusive design within the profession in the future.

With regards to the inclusivity of teaching the results were mixed, with some students feeling there was diversity of teaching staff and methods whilst others felt there was a lack of diversity. This I believe can be attributed to their personal experience and the stage of their educational journey.

When asked which areas of the built environment discriminate there were a wide variety of responses which centred around education, the built environment, construction industry and practice.

It became clear that the undergraduate and post graduate participants had very different experiences and feelings about the way they were being taught about inclusive design and how inclusive their educational experience had been to date.

Padlet Page: On line interactive discussion board

On completion of the questionnaire, participants were invited to populate the interactive discussion board with information relating to the research topic of inclusive design and equality and diversity within architecture and architectural education. The padlet page was set up to provide a safe place to raise potentially sensitive topics but also as an on-line resource. The intention was to identify an understanding of the current interest and knowledge of the research group and to create an interactive research tool which tested different ways of teaching and peer learning. It was also a useful test to identify whether this on line resource could be used within the curriculum.

Padlet Page: Analysis and Findings

The padlet page was a success and has continued to be used by the participants after the workshops were complete. There developed a sense of community for the members of the page and led to further discussions out with the study.

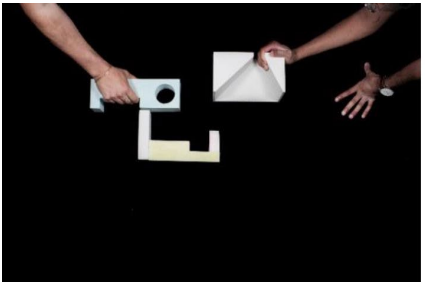
The information uploaded on the padlet page and the finding from the on-line survey were collated and through using thematic analysis a series of themes were identified for discussion within the workshops.

The themes identified for discussion were as follows:

- Gender
- Race/ Ethnicity
- Disability and the ageing population
- Mental Health
- Elitism

Within the participatory workshops a model was used as an engagement tool where participants were

asked to collaboratively explore the five themes identified through a physical artefact. The intention was that the model would act as a tangible teaching tool to create a collaborative response and as a participatory tool acting as a discussion starter. This design artefact was designed to draw out tacit knowledge on the themes identified and the participants' relationship with the built environment.



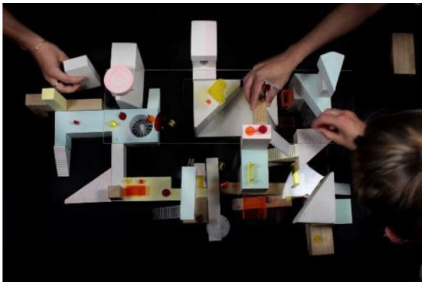


Figure 1, 2. Responses on Perceived Effectiveness of Green Infrastructure. Source: (Author 2020)Figure 1 + 2: Engagement Tool: The Institute of the Everyday. Source: (Missing in Architecture)

The engagement tool was a model called 'The Institute of the Everyday' and was designed as a collaborative piece where I worked with students to create an interactive model which investigated the inequalities that exist within society and how they manifest themselves within the built environment. This was done as part of a collective for which I am a co-founder called 'Missing in Architecture' and the model has been part of a series of exhibitions throughout Scotland.

5. WORKSHOP 1

The first workshop consisted of 4 first year students. From the outset the participants were keen to use the engagement tool and were happy to work together to develop collaborative responses to the themes identified. The discussions that developed around each model were mainly focused on the built environment and the profession with less emphasis on architectural education. This can be seen to be as a result of their limited exposure to the architectural curriculum to date.

Through the use of colour and the different shapes and materials of the blocks, the participants were quickly able to construct a narrative which identified the issues of gender that exist within the architectural profession. With regards to the identification of gendered spaces the discussion extended to the public realm and feelings of security.

On the second theme of disability and the ageing population, again the participants worked well to develop a collaborative response to the theme. As the discussion developed themes around mental health were also discussed. The physical representation focused on the lack of dignity and the thresholds within the built environment that supported able bodied individuals. The participants were comfortable to talk about the three topics and drew on personal experience and tacit knowledge to develop their response.

When asked to consider race and ethnicity within architecture and the built environment,

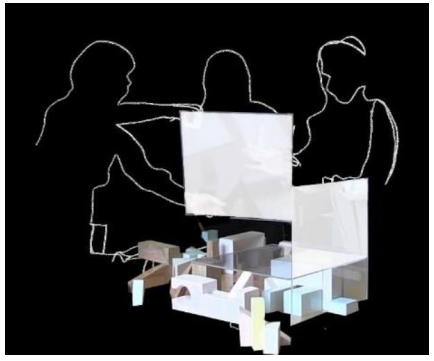

Figure 3. Workshop 1: responding to issues of gender. Source: (Isabel Deakin)

there was a hesitancy to engage with the topic although half the group identified as BAME. There was a general feeling that the built environment was not discriminatory and although the profession was predominately white, it was not a subject that the participants felt they had knowledge of to be able to discuss it in detail.

6. WORKSHOP 2

The second workshop consisted of 7 participants, three fourth year students and four fifth year students. Unlike the first workshop there was a hesitancy to engage with the model and the participants were less willing to work together on a single piece and found it easier to discuss the themes in a wider sense without the need to construct a narrative or use the engagement tool to explain their views.

The discussion showed a depth of knowledge on the subject of inclusivity, equality and diversity within architecture as a whole but focused mainly on architectural education. There was a sense of frustration at the lack of support within current educational systems to allow the participants to further their knowledge and be supported in their interests around these themes.

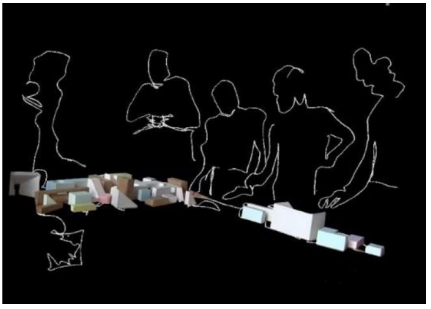

Figure 4. Workshop 1: responding to issues of gender. Source: (Isabel Deakin)

The discussions that developed around the theme of gender were similar to the first workshop and the model that was constructed had used a similar narrative to establish the form although this was not done collaboratively. The discussion focused more on equality within the profession and work/life balance with issues of exploitation within practice being highlighted.

When discussing disability and the ageing population the group recognized the awareness that disability extended beyond the physical. There was a hesitancy to establish how architecture could positively support other non-physical disabilities and a general agreement that this was an area which was not discussed within their architectural education.

The theme of race and ethnicity was an area that these participants felt strongly about. They related this to the lack of diversity and transparency of their education to date. There was a desire that the architectural education as a whole should be de-colonialised and that this should be done throughout the curriculum encompassing history and theory and studio practice. There was also a feeling that without a more diverse body of staff with different specialist areas the participants' interests and specialisms could not be supported.

The engagement tool was successful as a teaching tool and a discussion starter. By allowing the participants to build something it facilitated the discussion and in some cases the building blocks were used as safety blankets, and were hugged when discussing sensitive topics. The different interactions due to the size of the group showed that this type of teaching method is best used with smaller groups who can work closely together but is a valuable tool to allow a variety of voices to be heard.

7. REFLECTIONS

On completion of the workshops, both discussions were transcribed. Thematic analysis was then undertaken with areas of interest identified for further discussion at the focus group.

The focus group consisted of 7 participants with a mixture of participants from each of the workshops. Through the use of post-it notes we discussed ways to develop the curriculum to support a more inclusive architectural education. This was designed as a way to create a positive conclusion to the volunteers' participation within this Action Research Project. It was also designed as an informal discussion where prompts from the workshop were used to facilitate conversation and post-it notes were issued to allow for comments to be made even if the participants were not comfortable discussing them.

The participants were all very vocal and happy to discuss and question one another and there was no hierarchy within the group although they were from opposing ends of the education system. This correlates with the feminist principles which formed the basis of the structure for the project. The participants suggestions for the curriculum and conclusions from the workshop were analysed and the recommendations draw on these discussions.

The design of the Action Research Project itself was also testing a diverse range of teaching methods that supported a feminist approach to pedagogy. The success of this can be seen from the engagement of the participants. Many of these teaching approaches have now been tested further within the wider teaching practice within the school.

My recommendations centre on development within the studio environment and are as follows:

- Diversification of the reading lists, precedents used by staff and approaches to architecture and design especially when developing studio briefs
- Amend curriculums to support inclusive design and to include client's needs in the aims of the course
- Diversify the teaching styles to support a diverse cohort
- Development of peer support groups and mentoring schemes to support exchange of knowledge from a diverse cohort
- Develop inclusive design principles that should be embedded in each studio brief to support designing inclusively within the studio

Although this Action Research Project was based in one school these suggestions extend to the wider architectural curriculum across many Schools of Architecture.

CONCLUSION

The conclusions and recommendations were developed through collaboration with the participants of the project and through creating a supportive environment and through using diverse teaching methods it allowed for a sense of empowerment amongst the participants and individual voices to be heard whilst always respecting the diversity of personal experience. (Cohen 2007)

Steps are being made through the current diversification of the studio briefs within the undergraduate and postgraduate course at the Glasgow School of Art and the development of the wider curriculum across the Mackintosh School of Architecture. This can be tackled at a micro level within individual studio briefs, reading lists and inclusive teaching practices of individual tutors as suggested in my recommendations but also should be developed at an institutional level and a policy making level.

The next generation of architects should be challenged to design holistically with the highest regards given to the inclusive nature of the built environment and the diversity of the end users. They should be given the tools and the opportunity to do this and for this to be taught through more inclusive teaching methods which allow the students individual specialisms to be nurtured and supported.

PAPER #8.13

DESIGN GUIDELINES FOR COMMUNITY SPACES IN HOUSING

Alex Mitxelena[a], Ramon Barrena[a], Beatriz Moral[a], Enkarni Gomez[a]
[a]University of the Basque Country, Donostia – San Sebastian, Spain

ABSTRACT

What should architecture be like to meet people's needs and create and strengthen communities? This is the question we are trying to answer in this paper.
To do this, we need, first, to be able to name what the needs of the human being are, and Manfred Max Neef helped us to do so. According to this renowned economist, peoples' fundamental needs are the following: subsistence, protection, affection, understanding, participation, leisure, creation, identity, and freedom.
None of these needs can be satisfied in isolation, showing that human beings are intrinsically interdependent, that is why we are fated to live in community. This idea is central for feminist economy, that is why we also integrate this vision in our work, particularly, the contribution of Amaya Pérez Orozco, who collects, in turn, the idea of a good life or good living (sumak kawsay, a Quichua term that has become a central concept of a political debate around the commons and our relationship with nature).
Likewise, we have also been inspired by collaborative housing (co-housing) that, on many occasions, have been designed to meet the needs of the community, experimenting extensively with shared spaces.
With all this, we have developed a proposal that identifies the aspects to be considered in the design of housing to meet human needs and place the community in the center.

KEYWORDS

Housing; architecture; design; guidelines; care; community space; multifunction; mix of uses.

INTRODUCTION

Housing and community on a human scale

Our main objective is to promote an architecture that meets human needs and facilitates people to enjoy a good life, with a special emphasis on the importance of the community in this matter.
We take Amaya Pérez Orozco's definition of good living or good life:

> It must be a notion that responds to the basic conditions of existence of vulnerability, interdependence, and eco-dependence; Have a multidimensional understanding of well-being and understands that this is an incarnate experience, but always lived collectively (Perez Orozco 2014, 229). (own translation)

Architecture must face the challenge of what should be like to build for a good life, providing solutions and addressing the issue from an architectural point of view.
We take the community as a starting point to address the issue of human needs because the community is where these needs are to be met. Therefore, we are so interested in shared spaces: they are essential if we are to question the classic division of productive/reproductive work and the current isolation of the homes.
We are particularly interested in common and intermediate spaces since they are places that are shared and from which we could expect much more. In our environment, these spaces are generally small, untapped, and devalued. However, they can play a particularly important role both in responding to individual needs (collectively managed) and

in providing meeting places where personal bonds between neighbors are to be created. We are not so interested in attention or conciliation or in the division of labor as productive and reproductive. We prefer to ponder over the vulnerability of life, its precariousness, the human interdependence, and the conditions needed for a good life. All human beings are vulnerable and interdependent, and we must be taken care of throughout our lives, sometimes more than others. As Pérez Orozco says:

> (...) directly associated with feminism, we think that life must be thought of from its vulnerability and interdependence, dismantling the false, harmful, and masculinized chimera of self-reliance as an existential objective and its hidden mirror of immolated and feminized dependency. For us this objective is fundamental: taking out responsibilities from households, putting them in the common and the visible, dissociating the task of sustaining the life away from femininity, ending the sexual division of work and, ultimately, building how this is going to be done in terms of collective and democratic responsibility (Perez Orozco 2014, 226).

The fundamental needs

There is no doubt that it will not be easy to land when jumping from a notion as wide as good living. That is why we use the work of Manfred Max Neef to make specific proposals. Max Neef was a Chilean economist, political scientist, and environmentalist of international reputation. One of his main contributions is in his book Desarrollo a Escala Humana (1986), where he proposes a matrix in which he identifies the nine fundamental human needs. The main postulate of the proposal offered in this book is the following:

> The life quality of people will depend on the possibilities that people must adequately satisfy their fundamental human needs (Max Neef 1986, 16).

Max Neef identifies the following needs: subsistence, protection, affection, understanding, participation, leisure, creation, identity, and freedom. Nine may seem few when we tend to think that human needs are endless. This is, according to the author, because we assume incorrect assumptions:

> It has been believed, traditionally, that human needs tend to be infinite; that they are constantly changing; that vary from one culture to another, and that they are different in each historical period. We believe that such assumptions are incorrect since they are the product of a conceptual error. The typical mistake that is made in the literature and analysis about human needs is that the fundamental difference between what is really needed and what is satisfying of those needs is not explained. It is essential to make a distinction between both concepts (...) for both epistemological and methodological reasons (Max Neef 1986, 41).

To clearly understand what fundamental human needs are, Max Neef differentiates between needs and satisfiers. This can be easily understood with two simple examples: if subsistence is a necessity, food is a satisfier; If affection is a necessity, friendship is a satisfier. Max Neef formulates these two postulates like this:

> First: The fundamental human needs are finite, few and classifiable. Second: The fundamental human needs (such as those contained in the proposed system) are the same in all cultures and in all historical periods. What changes, through time and cultures, is the way or means used to meet the needs (Max Neef 1986, 42).

Now, the author adds:

> (...) there is no biunivocal correspondence between needs and satisfiers. A satisfier can contribute simultaneously to the satisfaction of different needs or, conversely, a need may require different satisfiers to be met. These relationships are not even fixed. They can vary according to time, place, and circumstances (Max Neef 1986, 42).

The author assumes universal character of these needs because, although we lack empirical evidence to prove it (as he acknowledges), "nothing prevents us from talking about its social-universal character, as needs whose realization is desirable to anyone, and whose inhibition, also for anyone, must be undesirable "(Max Neef 1986, 53).
Max Neef does not talk about good living; however, we think that his approach is close to this concept because he has an integrative approach to the fundamental needs, and he is concerned about what he calls the quality of life. We have opted for this author when developing our methodology because he offers a tool, a matrix, that can be very useful for an architectural intervention for it takes human needs from a broad point of view (beyond material needs and including subjective ones).
Our work has been, precisely, to apply this matrix to the built space to make specific proposals for the construction or modification of spaces to create the basic conditions of good living.

The satisfiers

Satisfiers vary depending on the context, that is, human beings have found different solutions for the same need. However, the approach or perspective with which that solution is given may not be positive. Thus, Max Neef describes a series of negative satisfiers that prevent in the long run from satisfying the need for which they were created because they generate a false sense of satisfaction, or because they make difficult or do not favour the satisfaction of other needs. An example of a negative satisfier would be armaments to meet the need for protection. In architecture, gated communities are an example of this, houses that are isolated from their environment and that prevent the free movement of its inhabitants. Or zoning in urban planning, separating or segregating uses (normally associated with production), to the detriment of security or conciliation.
The positive satisfiers are what Max Neef calls synergetic, and they are "those who, by meeting a particular need, stimulate and contribute to the simultaneous satisfaction of other needs" (Max Neef 1993, 64-65). An example would be food (preparation, consumption, distribution, commensality, etc.), which satisfies more needs than feeding, for example, being a way of establishing bonds with other people, identity, or affection. An example from the architecture would be the squares, synergetic places par excellence, since they carry out many activities and respond to various needs: it is a place for meeting, play, market, community activities, festivals, etc.

Synergetic spaces

This perspective of synergistic satisfiers helps us think about spaces that fulfil more than one function. This is especially relevant if we think of intermediate spaces - those places that, for example, connect spaces that have an assigned function. Between the street and the house there are spaces that are only thought of as passages (and because they have no major interest, the tendency is to reduce them as much as possible). Let us think about making these spaces visible and giving them, identity and we will see that they may serve many more functions, for example, to foster interaction between the neighbourhood and the community.

This will also make us think of a more permeable relationship between the private and public spheres. The houses and the people living in them shall not be isolated from their community; we should have to be looking for reducing unwanted isolation that is so frequent in our cities.
It is also about promoting non-hierarchical or multifunctional spaces, places in which life happens, with its complexity, uncertainty, and disorder.
We can imagine neighbourhoods that integrate the communal with mixed programs where the houses are supplemented with working spaces (thus responding to the needs of subsistence and creation), health services (to respond to those of subsistence and protection), educational and participatory cultural services (for understanding, leisure, participation, and identity). Environments that integrate several generations (responding to the needs of protection, affection, understanding, participation, and identity), different beliefs (identity, freedom), that allow and invite people to participate, to express themselves (creation, freedom). Environments in which the community is organized to collectivize care (affection, participation, identity).
In the collaborative housing movement, the ideas of integration of productive and reproductive activities, and the collectivization of care are well established, so that intermediate spaces, meeting places and multifunctional spaces become particularly important. It would be interesting to be able to spread these practices of collaborative housing to other environments with no need to build from scratch but to introduce them into existing spaces.
It is also important to make visible, recover and strengthen the practices that are still carried out spontaneously in certain environments that generate suitable spaces for meeting, exchanging, creating bonds, and favouring the creation of a sense of community.

We are aware that the built space is only one of the necessary ingredients to have a healthy community, but also that it can be a serious obstacle. Community life mainly needs people. Therefore, we want to think of the architecture for the creation of community as an architecture that creates environments that invite people to occupy them, as a kind of gardening for butterflies whose objective is to create environments that attract and invite them to stay.

1. THE DESIGN OF THE SPACES FOR A COMMUNITY

The design of spaces for communities consists of three parts:
1. Community
2. Activities in community spaces
3. Characteristics of community spaces

In Community we address the issue of what the characteristics of a community should be so that it responds to the fundamental needs.
In Activities in community spaces, considering the kind of activities that shall be possible to carry out in them, we find four types of activities: community creators, expansive, functional, and expressive.
And in Characteristics of community spaces we identify the aspects and elements that are necessary for these spaces so that they fulfil their function in the best possible way. We identify structural, technical, quality, accessory, and subjective characteristics.
Next, we will develop this proposal in detail.

1.1. Community

The built space, the architecture, is not enough to solve the lives of people and groups in a satisfactory way, but it is a necessary condition. Similarly, an ideal space is of little use if the community does not have certain characteristics if it does not foster certain values. There will be little use for well-

designed meeting spaces if the inhabitants have no desire to interact with each other.
We describe here some of the characteristics that these communities should have, always keeping in mind that our goal is to get communities prepared to respond to fundamental needs.
1. The community should facilitate or guarantee good treatment among people in the community so that they feel cared for, safe, heard, respected, and accompanied.
2. The community must keep in mind that not all people are equal, that they are not at the same vital moment and are not in comparable circumstances.
3. For the community no to enclose itself and isolate or become too dogmatic it would be suitable to have an appropriate size, feed the feeling of identity, maintain a good relationship with the environment and be open to change.
4. The community should have agreed rules of coexistence, systems of participation in decision-making, management, and maintenance. It must also have a good internal communication system and an adequate transmission of its values.
5. The community should be open to the neighbourhood, to the town, to the city, that is, to be permeable to its surroundings.
These aspects and those we develop later should be considered only as an initial proposal to think and debate how we want our communities to be.

1.2. Activities and community spaces

Spaces should not be designed for exclusive use (dining room, sleeping room, etc.), thus confining the number of possible uses to the number of available spaces. So, as there are many significant activities specific to fundamental needs, the spaces of a community must be prepared to welcome, facilitate, and promote these activities. Some of them will need exclusive spaces (or at least quite exclusive), but many others can be done in a multitude of different spaces, if these are suitable.
It is also important to consider the environment in which the community is to propose activities to the neighbouring people and not allocate space to activities that can be carried out nearby.
We define four types of activities and we have thought of them in spatial parameters:
1. Community creators: meeting, sharing, communicating, or talking, exchanging, and sharing.
2. Expansive: for enjoyment and personal development, such as reading, throwing parties, physical exercise, games, exploration, meditation, relaxation, etc.
3. Functional: activities that are part of the daily routine of our lives such as cooking, doing laundry, watering, hanging clothing, cultivating, making small repairs, etc.
4. Expressive: for example, exhibiting, painting, drawing, weaving, embroidering, writing, dancing, playing music, giving shows and in general any type of artistic or personal expression that can be carried out within the community.

1.3. Characteristics of community spaces

The community spaces are based on the idea of the synergetic satisfiers described by Max Neef. Sharing spaces must be conceived as an opportunity and enrichment, not something that has to be done precariously and in places of bad quality. Thus, the activities that are developed and the people who participate should be able to enjoy and share without creating annoying situations and discomforts. To have spaces of good quality, they must have certain characteristics. In this section, we identify and list some of them.
The structural characteristics establish the general parameters in which the others must be developed. We have identified the following:
- Multipurpose / transformable / adaptable
- Permeable
- Multidirectional

- Not hierarchical
- Sufficient
- Appreciated/qualified

Finally, we describe other technical and quality characteristics.

1.3.1. Multipurpose / transformable / adaptable

Multipurpose spaces allow creating spaces for people doing different activities to meet and melt. It also allows us to share experiences and knowledge and to increase the use of the spaces because there are more possibilities of use in time and in the type of activities.

These spaces might have different uses at different times, but they can also be spaces that host different activities simultaneously, without causing trouble. In fact, this simultaneity should be an opportunity to enrich activities by expanding and completing them, and, above all, to create opportunities for the relationship between people: carrying out collective activities reinforces relationships and the sense of community.

The furniture must also allow different use and be placed in various and unforeseen provisions.

1.3.2. Permeable

By permeability we understand the opposite of bunkerization, both of households and communities. Without compromising a clear delimitation of both the home and the community, it is essential to nurturing a certain porosity of both the community and its environment and the homes and their communities.

Thus, the uses and activities carried out in a community must contain the potential to open up to the environment, or host other people's activities; in the same way, it would be necessary to favour the passage of outsiders, at least in certain spaces.

Regarding the activities that are normally done at home (preparing food, caring, cleaning, sewing, painting, etc.), there must exist the possibility of carrying them outside, thus breaking the isolation to which they are usually confined. This allows us to share them, to support each other, or simply carry them out accompanied while weaving community. On the other hand, the community would also need access to the houses: if they were more penetrable it would be easier to know if someone needs help, support. Here we will have to face the delicate task of delimiting where privacy ends and where isolation begins, or where support ends and the invasion begins, something that, most likely, depends on people and circumstances.

Some use or activities require a certain degree of isolation so that this permeability is not always convenient. However, it may be the case that this need for isolation or privacy is necessary only at specific times.

Permeability requires, among other things, that there is a visual relationship between the spaces, as well as easy accessibility (free of obstacles such as walls, gates, impenetrable doors, etc.) that use porous delimiting elements.

1.3.3. Multidirectional

People can tour buildings or spaces following an objective or according to the use or the activity. Allowing different directions can create unexpected encounters between people who go to different places or who do different activities.

1.3.4. Not hierarchical

With non-hierarchical space we mean avoiding the existence of spaces that determine the place that people must occupy, putting some above others. A meeting room can take different forms, and these may or may not be hierarchical. There is no doubt that the way in which space is designed, in which its furniture and distribution are arranged, condition the way in which people relate to each other:

a rectangular table instead of a round one; chairs in a circle instead of rows; flat ground instead of stands, etc.

1.3.5. Enough

It is important that the spaces are sufficiently large so that the functions are not restricted and that there is room for change or adaptation, for improvisation. Having enough space (considering that enough is a totally subjective term) is not having to compete for it, not having to discard a significant activity due to lack of space, or leaving a certain group of people without space (as often happens with teenagers, but that can be applied to any other group).
To have enough space is to have spaces in which activities can be carried out in a functional way and with enough comfort. Having enough space is also important to feel comfortable in any space. It provides quality to life.
We need to have enough space to be able to carry out simultaneous activities so that they are compatible, something particularly important, for example, for caring activities, which are often carried out simultaneously with other activities.

1.3.6. Appreciated/qualified

It is important to give the value they deserve to certain spaces and certain activities, in particular to those that allow people to meet, establish relationships, foster mutual support and develop as individuals; these places and activities that encourage that the works for maintenance and reproduction of life leave the confinement of the home. It is well known that in many countries the laundries are not inside the house but in a common room. This is fine, but it is not so fine to place it in a dark and sinister basement. The laundry room, if it is a nicely designed, in an open, bright, and cosy space, can help to dignify the activity and to promote interaction between its users.

1.3.7. Other characteristics

We have classified the rest of the characteristics like this:
- Technical
- Quality
- Accessories
- Subjective

The technical characteristics are those that affect the habitability conditions, the physical aspects that must guarantee the well-being and comfort of people. We highlight the following:
- Thermal comfort
- Acoustic comfort
- Ventilation
- Accessibility

Quality characteristics refer to the impact on the mood of the people and the way in which they condition the relationship between them. In these we highlight the following by way of example, since the list may be longer:
- cosy space
- sheltered space
- spaces that generate a sense of security
- space that guarantees privacy
- convivial and friendly space
- outdoor spaces
- evocative spaces
- etc.

That is, the spaces we build or modify must be designed to have this good impact on those who inhabit them, avoiding creating inhospitable, cold, impersonal, suffocating, or insecure places.
When we talk about accessories, we mean these elements that populate or dress the spaces. These accessories must have the same purpose as the structural and techniques characteristics: they must favour the coexistence of different people and activities, improvisation, adaptability; they have to help generate pleasant, stimulating environments; to provoke encounters, exchange, dialogue,

communication, creativity, and imagination. Here we can only mention a few examples since the list could be endless, and each community will require different accessories to meet their needs and fulfil their wishes:

- moving elements
- places to sit
- means of expression
- internal and external communication tools
- plants
- games
- adaptable separation elements (curtains, screens, etc.)
- etc.

Finally, when we talk about subjective characteristics we refer to those aspects of the spaces that allow the development of subjectivity, identity, free expression, adherence to the community; spaces that allow spontaneity, diversity; spaces that we feel belong to us, that represent us, with which we feel identified and in which we find something of ourselves.

FINAL CONSIDERATIONS

We would like to finish by pointing out that another design of residential buildings is possible and exists. A design that is capable of surpassing the idea of bunker homes, where common spaces cease to be anonymous steps to go from one functional place to another; which considers common spaces as an opportunity rather than as a problem; that uses these spaces to weave community and generate life; and that gives these spaces visibility, uniqueness, and value, and also spares no resources to provide them. We believe that a building articulated around good common spaces (common resources, after all) improves people's quality of life, not only because it allows them to access resources that would otherwise be unattainable individually, but also because it represents the opportunity to weave those nets that are so essential to us in order to achieve a good life. If interdependence is our characteristic feature, let us make it a virtue and not a flaw.

PAPER #8.14

DISENTANGLING RELATIONAL SPACE: ADDING INSIGHTS OF THE EVERYDAY LIFE OF CHILDREN TO THE PROCESS OF URBAN RENEWAL

Johannus van Hoof[a], Erik Van Daele[a], Bruno Notteboom[a]
[a] KU Leuven, Ghent, Belgium

ABSTRACT

This research focuses on facilitating contemporary urbanity from a user central position, based on the creation of space. This research is approached from a perspective formed within the disciplines dealing with the production of space and based on the relational paradigm (Harvey 2004; Massey 2005; Löw 2016). It aims at developing new approaches to the construction of- and additions to the current urban archives on which spatial policy- and design frameworks are based. By bridging social and spatial knowledge in an empirical research of the case Muide-Meulestede in the city of Ghent (Belgium), it tries to transcend universalism by accurate location-bound knowledge, and deliver new entries to the spatial professional to tackle design challenges in contemporary Flemish urban conditions.
The paper describes the process of creating insights into the relational space of children in function of the development of an "age-friendly Recreational Structure" for the Muide-Meulestede district. It gives an overview of used methods to expose the local relational space of children living in the district, the knowledge contribution that a relational approach can offer to existing "urban archives" and how this knowledge can be used within a process of urban renewal.

KEYWORDS

Relational space; citizen centered design strategies; localism; socio-spatial limits; multiplicity.

INTRODUCTION

We live in a world in continuous transformation. We experience it from within a global sphere in which we have to actively relate ourselves to themes as the global economy, politics and climate uncertainties. This fluid world is characterized firstly by the unprecedented possibilities that globalization offers us, but also by the search for universal standardization (Stables 2019) to reduce the complexity that arises from this. As a response to globalization, there is a growing awareness of the value of the here and now, of the city, the neighborhood and the street in which we live (Madanipour 2003). More and more attention is paid to our daily life and its environment (De Certeau 1988) as our personal center of our global existence. In a world, where the network society (van Dijk 2012) organizes itself at the speed of lightning, reformulates, expands and merges into something else, and creates the right conditions for a wide diversity of social movements (Nicholls 2008). This is the field where the contemporary spatial designer, developer and policymaker have to position themselves, spatial professionals who are responsible for the development of the stage where all these dynamics take place.
This research is focusing on an actual process of urban development within the District Muide-Meulestede part of the city of Ghent, located in the Flemish region as part of Belgium. It focuses on a development process initiated by a collaboration between the residents of the neighbourhood and the urban services of the city, in response to the large-scale developments taking place around the neighbourhood. It starts from the desire

of the residents to have more control over their daily living environment, but also to take responsibility for it. In addition, it gives shape to the ambition of the city to develop a city, based on a participatory trajectory, to the needs of- and tailored to its residents.

This form of localism (Davoudi and Madanipour 2013) can be interpreted as a countermovement to globalism, as it offers the citizen the opportunity to give substance to its individual position within the global themes on a human scale. But it can also be interpreted as a countermovement to standardization, the reduction of the real complexity of the city in policies and design frameworks, where the need for knowledge of the local (Kuukkanen, 2012) has faded into the background.

With this in mind, the available urban archives as spatial theorezations, used and made by the spatial professional, seems to be not sufficient within the contemporary model of urban renewal. Space can no longer be treated as the container of materiality as a contrasting background for social activities (Harvey 1973). The socio-spatial qualities of space form the conditions of daily life. Space not only functions as the context of the social life it includes, it can be described as social-based spatiality. Space forms the stage (Foucault 1980, Soja 1989, Heynen 2013) for the processes that take place on it, where these processes describe their stage at the same time. This concept of space reflects the relationships between the individual, object and group (Gurvitch 1971, Massey 2005, Löw, 2017), space as a stage facilitates interaction and this interaction defines space.

This research looks for a new approach to create space based on the actual complexity that space as a stage includes. As a reaction to the reconstruction of New Orleans after Hurricane Katrina, Peter Marcuse described an approach, he called 'critical planning' to explore and to give answer to the actual complexity, which arose from this crisis situation. This research is building on the three steps of 'critical planning' he developed: expose, propose and politicize (Marcuse 2009). To expose this complexity, the research starts not from the perspective of the absolute space, the physical appearance of space, but from the relational space. The concept of relational space is approached from different disciplines (Harvey1973; Soja 1996; Massey 2005; Madanipour 2010; Heynen 2012; Tornaghi and Knierbein 2015; Löw 2016), this research starts from the position and the concept of space, that is used by the spatial disciplines (Khan, Moulaert and Schreurs 2013) and defines space as an active parameter. Insights in the relational space, are not the goal, the goal is to develop a new approach to the process of making space. This process of making space has a location and it includes a defined number of processes, it relates different collectives, individuals and objects. In this way the research has the aim to go beyond the high level of abstraction that the current process requires. From an anthropological and geographical focus on middle-range theorization (Merton 1968), within a perimeter actual processes can be identified, and mutual relationships can be mapped to expose the local relational space (Ong 2011). This research therefore does not lead to a universal set of variables to analyze a certain perimeter, a universal theory or method (Law, 2004), but to an approach to grasp the contemporary urbanity in order to create space and adjusted to the spatial professional.

This paper describes a case which explores the possibilities of a relational approach within a process of urban renewal in a Flemish urban context. This case is dealing with an actual project of city renewal, in collaboration with the city of Ghent. We focus on a part of this process: the development of an age friendly recreational structure directed to the neighbourhood Muide-Meulestede. It is a project with the ambition to deal with the actual complexity of the neighbourhood, developing space tailored to a broad diversity

of social groups, instead of just designing space for all. The case serves as a living lab to the research, where it uses this process as a case study at the same time. The paper starts with a description of the concept "age friendly recreational structure", how the framework of the research contributes to this development, and its meaning to the research. Next, it focusses on the methodology that was used to expose the daily patterns of children in the public space. It gives an overview the representation and projection of the material. The paper ends with the significance of this approach for a development process and how it contributes to the "propose" and "politicize" phases.

1. MULTIPLICITY AS A CONDITION FOR THE DEVELOPMENT OF AN "AGE-FRIENDLY RECREATIONAL STRUCTURE"

The concept, space as a stage, is the basis for the development of the "Age-friendly recreational structure" for the Muide-Meulestede district, which is currently being developed within a multi-disciplinary partnership between various city services and to which the research actively contributes.

The concept "age-friendly recreational structure" refers to the "play space web" (Dekeyser 2007; Gill 2019), a policy document used by various Flemish municipalities and developed by the Flemish NGO Kind & Samenleving. This policy document functions as a planning instrument, at the scale of a neighbourhood, which determines the playability and child-friendliness of space within current and future developments. A "play space web" focuses both on guidelines for the provision of child-friendly space, it creates guidelines to how this space can be designed, but it also maps the neighbourhood for child-related mobility issues. This instrument forms a framework for the design of playgrounds and contributes to the larger framework of urban development.

The idea of the "age-friendly recreational structure" was coined in a urban policy document that was devised by the city service of the city of Ghent "urban renewal". It is based on the hypothesis that an integrated approach to a recreational structure provides added value for the diversity of users of the public space, but also that this approach can lead to an instrument that can have an impact on a diversity of scales in the process of spatial development. The application of the concept is experimental, it creates its shape within the living lab of this research in the collaboration with the city services.

The word age-friendly in "age-friendly recreational structure" represents the ambition to make the public domain accessible and attractive for various target groups that are located in all age groups from young to old. The word recreational indicates a focus on activities that fall outside the daily obligations. The word structure in "age-friendly recreational structure" stands for the ambition to develop "1" structure instead of various structures aimed at individual target groups or different use. Together, these words in the title of this project represent a new approach to urban development, which seems evident, but in practice it is not.

The development of one structure for various target groups starts from the fact that these target groups are going to share space and relate with each other within this space. The space in which this takes place is read differently by each target group and each target group sets its own requirements and wishes for this space. The development of one structure for various target groups, assumes that the reality in which these various views of different users are coming together in the public domain and thus dealing with the multiplicity (Massey 2005) of space.

Within the classical approach, this multiplicity is disentangled based on the representation of the various target groups by the different city services involved in such a process. From the perspective of the individual city

services urban policy is made applicable to a local context. This leads to a form of urban development that is based on a standardization of reality and ignores the local interests of the users of the space. It is an approach based on statistics, it focuses on a statistical availability based on proximity in which the relative aspect (Löw 2017) is not recognized. This form of urban development comes from a perspective in which all the nuances of daily life have been extracted and reduced to policy rules that serve as conditions for the urban environment. This approach uses the single perspective of the target group that represents an urban service. This statistical approach offers few reasons and conditions for entering into relationships with other services and the target groups they represent.

The development of an "age-friendly recreational structure" requires a new approach which exceeds the limitations of the individual city services. Such an approach starts from a different notion of how we learn and debate the city. In order to meet the spatial demand, and in this case to learn the motivation for recreational use, of a diversity of users and to coordinate these, they must not only be mapped, but we must also learn the conditions to these spatial demands. Just like the motivation, these conditions are specific to a target group, are social based. The conditions provide insight into the behaviour of choice, of target groups to make use of the recreational facilities that the neighbourhood offers them. The knowledge of both the motivations and the conditions for behaviour in the public domain, gives an image of the actual use of facilities in an existing and of a future situation, in which not the spatial presence but the spatial use is central. The knowledge of the conditions can be used for strategic interventions in the space or interventions in the relationships between different target groups.

These conditions cannot be derived from analyses of absolute space or relative space, but they result from the processes or routines that describe these two forms of space. The research focuses on this concept of space, in which processes are normative. It starts from the relational approach to space that David Harvey described as follows: 'The relational view of space holds there is no such thing as space outside of the processes that define it. Processes do not occur in space but define their own spatial frame.' (Harvey 2004). A process, like a routine as walking the dog through the park, manifests itself in space and time. The relational space interconnects with the absolute space, you are walking with the dog through the absolute space which is all around you. The extent to which the absolute space becomes significant to a process, is determined by the ordering forms of proximity (Löw 2017), the relative space. You are walking in the park, the space outside the park becomes irrelevant for this routine. A process not only relates to space but also to other processes, during your walk, maybe you or your dog will interrelate with others in the park, while you are sharing space and time. Relational space is not only pre-structured by the absolute space but also by adopted conventions, power relations (Foucault, 1977), formed by other processes. You know that you and your dog have stay on the paths and are not allowed to cross the flower beds. Different processes active in the same absolute space creates forms of multiplicity (Massey 2005). Your dog could be interested in the ball, some children are playing with, But to avoid a conflict you are taking another route. Understanding the city by its relational space starts with accepting the multiplicity of space. This approach asks for knowledge of spatial qualities, spatial relations and power relations experienced by individual users of a certain place. It asks for knowledge of the absolute, relative and relational space and its interconnections.

Understanding space from a relational approach starts from understanding the various individual processes present in

space: the daily patterns of everyday life from the different perspectives of individual users of a certain place. To develop an "Age-Friendly Recreational Structure", the task of the spatial professional is not only to switch between the various layers and scales of the absolute space, but also to be able to switch between the various perspectives on this space from the multiplicity exposed by the relational space. In case of the development of the age-friendly recreational structure, knowledge of these perspectives is present at the individual (social) urban services. But the objectives of these urban services and thus the methodologies used to develop insights of these perspectives do not provide knowledge of the spatial aspects of these perspectives.

The concept of relational space generates a new perspective and offers opportunities to reflect on the existing city. As such, the relational approach embodies the 'expose' step within the 'critical planning' , which Marcuse described. Knowledge of relational space creates opportunities to not only understand the multiplicity of space, but to actually work with it in the 'propose' and 'politicize' steps of the process of urban renewal.

2. EXPOSURE OF THE RELATIONAL SPACE: THE DAILY RECREATIONAL SPACE OF CHILDREN IN MUIDE-MEULESTEDE.

To clarify the forms of knowledge that can be exposed by insights into relational space within a given perimeter, this paper describes a study of the recreational use of space by children between the ages of 6 and 12, within the limits of the Muide-Meulestede district. The importance of the position of children in the urban planning process is actively embodied by UNICEF in its goal to develop child-friendly-cities (UNICEF 2020). The freedom of movement of children in an urban environment is more and more compromised by the increasing perception of traffic- and social dangers, which limits their spatial options. Children become more dependent on the accompaniment of their parents in their daily routines, with a result that their voice is less and less heard in the planning process (Freeman and Tranter 2011). This observation gives reason to include the spatial use of children as a minimum condition to the process, the same applies to the spatial use by the elderly within the development of an age-friendly structure.

The research of the recreational use of space by children took place in 2017 and was done with support the two primary schools present in the neighbourhood and had a total of 54 participants spread over 3 age categories: 6-8, 8-10, and 10-12 years. The applied methodology was based on the mental mapping (Lynch 1960) of the recreational space that the children use in their daily life. The mental maps served as the conversation starter for a short interview, focusing at the experiences of the space, the limits of the used space and what these limits determine. The drawings and the interviews were used a to create a perspective tailored to the children to analyze the absolute space, to define limitations of the relative space (Löw 2017) and to understand their behavior in spatial use through insights of the relational space (Giddens 1984). The findings from the study were reflected and further refined in workshops based on a photo voice (Wang 2016) methodology and walking interviews (Evans 2011) in which both children and local agents were involved.

The children were asked to draw their daily environment, with their own house in the street in a central position. They received a canvas that shows an empty street, a plastic drawing template that contains a number of archetypes of dwellings and spatial facilities, which can be used to draw, local situations of the Muide-Meulestede district and pens in various colours. A drawing focusses only on the elements the children give an importance do draw. Different colours are used to describe elements they like, hate or

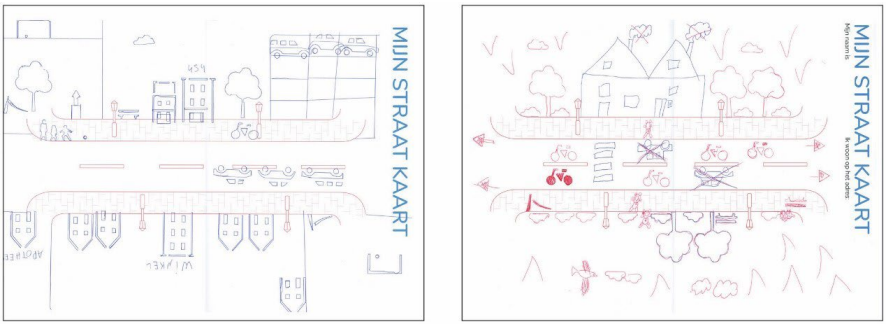

Figure 1. Examples drawings children. Source: (Author 2017)

would like to improve. To start this exercise a drawing was shown as an example, where the considerations within this drawing were also indicated. This drawing served as an example, but this explanation also functioned as a moment to ask a number of structured questions to the participants in an informal way. This exercise took 20 minutes, after 20 minutes the children were asked to describe their drawing. These short conversations gave the possibility to question uncertainties or to delve deeper into specific elements coming from the drawing or the conversation.

This method was developed based on a number of objectives: an attractive format in which children want to participate based on their own decision; a format that can be completed within the attention span of children from 6 years old; a format to which children who cannot yet write can contribute; a structured approach with sufficient liberties that gives space to the unpredictable ideas of children; a format that focuses on the current situation and does not raise expectations about future developments; and a format that bridges social and spatial knowledge in a single exercise. The used method was directed to children form the age 6-12 years and living in the district Muide-Meulestede. As a method to grasp relational space, it is focusing on the spatial stage the children are using in their daily recreational process. The method provides clear results to the spatial use, and the social and spatial conditions that form the conditions of this use. The method exhibits deficiency in the aspect of time that is inextricably linked to a process and therefore the relational space. Time is individual and the children each have their own sense of time, which is difficult to grasp in such an exercise. But time is also an essential component to relate different processes or routines, of the children or other user groups. The research therefore proceeded from assumptions to imposed benchmarks over time due to external influences, such as school times, dinner time and bed time.

3. ENTANGLING RELATIONAL SPACES: INSIGHTS IN THE SHARED SOCIAL AND SPATIAL LIMITATIONS OF SPATIAL USE.

The results of this study firstly provide an accurate image of the recreational use of space by individual children. It provides insight into when, where and why they use the collective space in the neighbourhood. The use of space responds primarily to the will and the need to play and by this to expand their limits and to challenge themselves physically and socially. But in addition, it also gives an impression of the overall spatial qualities of the neighbourhood: in many

cases, children indicate that they do not have access to private outdoor space in their home environment. The collective outdoor space serves as an extension of the private space. The outdoor space is therefore part of their process that they go through every day. In addition to playability of space, many children attach importance to places to withdraw, alone or with friends; they look for qualities that are not available in their private space.

The research also shows the differences between target groups in their spatial demands. First there are clear differences between the use of space by boys and girls. To give an example, in the study, boys indicate that they use public space for spontaneous meetings, where girls more often plan their use of public space to meet with friends. Cultural differences are also noticeable. For example, certain children with a Turkish background are mentioning they are allowed to stay outside much later in the summer then the children with a Belgian background, but they also have a much wider reach in the neighbourhood. Age, as a reflection of the degree of social and spatial knowledge a child acquires while playing, also counts as a factor that determines the use of space. However, we can state that this factor is in case of children living in Muide-Meulestede less important than you might expect (Dekeyser 2007).

The specific individual spatial demand that is exposed reflects the spatial qualities of the neighbourhood. This demand corresponds

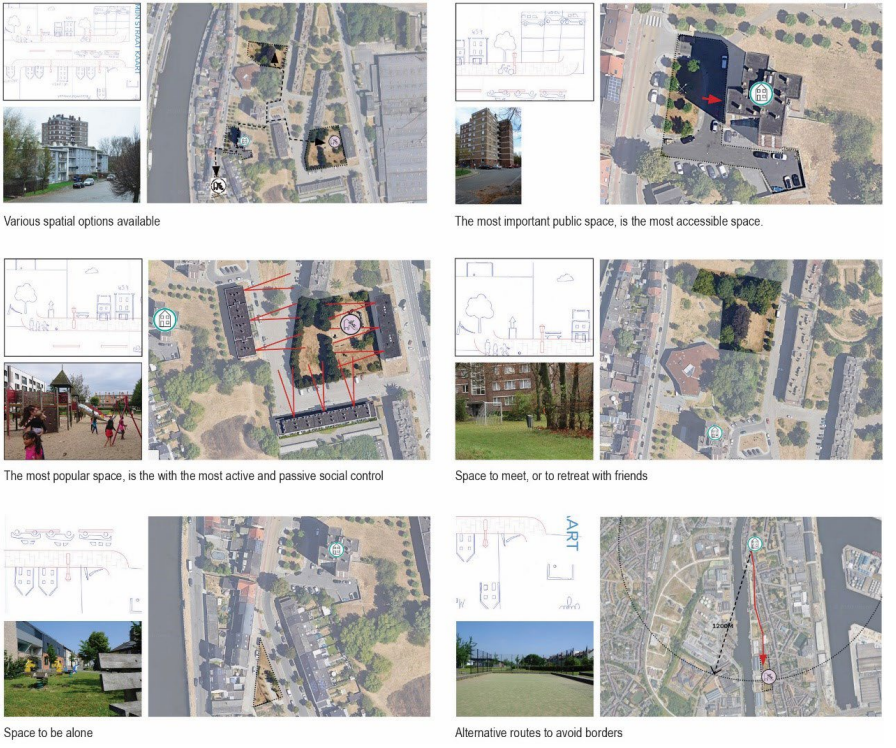

Figure 2. Example spatial analysis output workshop children . Source: (Author 2018)

to the statistics of the neighbourhood (Stadsmonitor 2017), it corresponds to the very high population density and development rate. But unlike these statistics, the results not only have a signaling application, they provide a detailed image of how these individual users act according to the opportunities they have in time and space.

By not only analyzing the individual disentangled relational space, but also how different relational spaces relate to each other, new knowledge layers of the neighbourhood can be developed, which relate social and spatial aspects to each other and have their origins on various scales. The children's drawings described the space that was considered to be their relational space, but by doing so they also described which space does not belong to their relational space. With this they indirectly drew the limits of their relational space.

Where the demand of space was briefly discussed above, the entangled data gives an impression of how the children give substance to these spatial demands within the possibilities the neighbourhood has to offer. By combining and relating all spatial limits of the individual drawings, an image of boundaries in the neighbourhood was created, which can be explained by the spatial context, but also by the power relationships that it results (Giddens 1984). It gives an accurate image of spatial boundaries in the neighbourhood that are supplemented and reinforced by mental boundaries. These mental boundaries describe the actual accessibility of a place for the children living in the neighbourhood.

These mental limits are in many cases determined by interpretations of safety. The theme of safety arises in relation to the mobility issue which is arising when bridging the distance between the front door and a suitable place to recreate in the collective space. Forms of spatial safety also arise in the research, relationships between the living space and the public road, unclear spaces with little social control, unsafe situations at a more detailed level, are determining factors that can influence the play of children. Another factor is social safety, multiple use of space can have both a positive and a negative impact on the presence of a specific group in space. The research shows that lively places with overlapping use in space and time are the most attractive by a diversity of user groups. These places are provided with various forms of social control due to the diverse use; it makes the places predictable and gives the feeling of trust and safety. Spaces that have multiple uses, but where this use does not overlap in time, in the way that the relationships between this use are unclear, are more likely to be labelled as unsafe.

This sense of security is essential for the children's use of space. This sense of security should not only be present with themselves, but also with their parents, their friends and their friends' parents. Safety thus determines the mental boundaries within the neighbourhood and thus the accessibility of the facilities available for the children. In addition, it largely determines the attractiveness of a space for daily use as an extension for the private space.

The children in the study indicate that the attractiveness of a playground is not determined by the facilities available, but by the aforementioned factors: accessibility and safety. These factors determine their use of space, only when they can choose between different spaces that meet these conditions in the same way, they have the opportunity to choose the most attractive facilities. This means, for example, that the children are playing soccer on an open field with trees as goals, which is only a hundred meters from a soccer field facilitated by the city. For many children, attractive places in the neighbourhood are places that are challenging on a spatial or social level. These spaces do not necessarily correspond to the spaces designed for them, when these

spaces do not meet the basic requirements to use this space.
These limits describe the conditions of how children deal with physical and mental borders, with spatial and social risks and gives an image of their personal goals and interests. These conditions find their form in elements in absolute space, relative space and the power relations that shape their relational space and can often be described in terms of accessibility, safety and attractiveness. These themes itself are already in the picture in the process of urban renewal, but the relational approach adds a detailed layer of socio-spatial conditions to these individual themes. It creates an understanding of the perspective of how children use the public space and creates an image of the spatial demands of a social group without an own voice in city planning.

CONCLUSION

Insights into the conditions of the use of space, both spatially and socially, open up opportunities to influence the process of facilitating the staging for our daily life. The relational approach is based on a multiple use of space and exposes the conditions of this use and in this way it creates insights on challenges and opportunities arising from spatial and social issues. With this, a relational approach contributes to the urban archives that originates in accurate local knowledge of the end-user's actual use of space. It delivers user-central data and therefore goes beyond forms of standardization. These conditions are recognizable by the residents, but that does not mean that they experience them consciously. Insights into the conditions offer opportunities to adjust the stage of daily life to the conditions, but it also provides the framework to reflect. Shared exposed insights of this knowledge by policymakers, designers and local residents make the process accessible and democratic. This knowledge forms new guidelines that encourage new urban alternatives to be proposed within both top-down and bottom-up approaches. These guidelines therefore not only function as a design framework, but also as a framework for reflection and can be applied in these two capacities within a participatory strategy.
However, the main benefit of this approach lies in understanding and getting a grip on the multiplicity of space. The case described in this paper shows the disentangling of the relational space of one relatively homogeneous focus group and what we can learn from the individual perspectives within this focus group. As such, this provides a knowledge contribution to the current process, but it also describes relationships to other focus groups. In order to develop an age-friendly recreational structure, other groups must also be addressed. The research is based on the hypothesis that a relational approach can create an understanding of existing processes of other focus groups as it did in the described case, but above all, that it can make the multiplicity of space more transparent and provide an innovative foundation, for the "propose and politicize" steps. Further research within the case study, directed to focus groups like the elderly, or youth, will be needed to provide an answer to this hypothesis.
As part of the expose-step within the 'critical planning' approach of Peter Marcuse, the relational approach exposes the motivation and conditions of the actual use of space. This step of the research is not necessarily participatory, but it makes the process accessible in the phase where proposals are developed. These proposals are captured in policy documents after, on the one hand, an assessment by urban policy, but on the other hand, the assessment of a proposal against the exposed conditions within a participatory trajectory. In this way it completes the circle of a form of spatial development, which stands for a dynamic, accessible and therefore democratic process.

PAPER #8.15

THE NEW FORMS OF RESIDENTIALITY FOR THE SENIOR "INCLUSIVE" HOUSING

Martina Nobili[a]
[a]Department of PDTA – Sapienza Università di Roma, Roma, Italy

ABSTRACT

In recent years, the issue of inclusion has taken on a central role in the European political debate so as to introduce welfare instruments and strategies dedicated to different sections of the population. Among these, the most vulnerable in situations of fragility not necessarily, and not only, of an economic nature deserve more attention. We are referring to the elderly, whose definition should be reviewed both considering their chronological age - in 2050 1/5 of the world population will be over 60 (WHO, 2015) - and above all considering the aspects linked to the needs of each "kind" of old people. The needs are dictated by the economic, social and physical conditions of each Senior: all elements that must be considered in order to operate within the different urban regeneration processes both involving individual buildings and entire areas of the city. We can talk about Senior Housing, but this doesn't mean creating entire buildings or neighborhoods of elderly people only, but working to design new forms of residency where the elderly can be included as leading actors, not as extras. In line with the principles of active aging, already proposed by the WHO at the end of the 1990s, autonomy must be stimulated and fed as much as possible until high and intensive levels of assistance are requested. To do this we need to work on developing new housing models where integration and intergenerationality can be the founding pillars. In this contribution some projects realized in Europe will be described, considered as case studies for the purpose of research, with the aim of highlighting the strengths and strategies that led to their elaboration.

KEYWORDS

Active aging; aging in place; non exclusive society; senior housing; social housing.

INTRODUCTION

Talking about Social housing means dealing with a multitude of welfare strategies and interventions in the residential area: the adjective "social" makes the issue complex and inquisitive in many aspects. Generally placing this adjective before the word "housing" allows to characterize this activity with respect to the users it is intended for both as regards its architectural-urban planning and for the methods of access to housing it creates. Social housing could be defined not as a category of housing but as a path for housing aimed at the inclusion of social categories for the satisfaction of their primary needs. Under the light of demographic trends, social categories would seem to expand to include new emerging "classes". The population in Europe is the highest average age in the world and more people live over the age of 65 and up to a very old age, significantly increasing the number of older people. Worldwide, the number of people over 60 has doubled compared to 1980 but the forecast is that, by 2050, it will quadruple the number of over 80 compared to now and that people over 65 will outnumber children who are under the age of 5[1]. Of course, a cause-effect relationship cannot be established between longevity and degree of self-sufficiency: despite aging, it invests the world population horizontally, there are peculiarities due to intra-individual and inter-individual differences (Fernandez-

[1] "Are You Ready? What You Need to Know about Aging .", World Health Organization, 2012.

Ballesteros , 2008) also taking into account the relationships of individuals with external factors related to the socio-cultural context . In Italy the speech of Niccolò Marchionni, Full Professor of the University of Florence and Director of the Cardiovascular Department of the Careggi Hospital, has had a significant impact during the 63rd National Congress of the Italian Society of Gerontology and Geriatrics (SIGG): "A 65 year old today has the physical and cognitive form of a 40-45 year old from 30 years ago. And a 75 year old that of an individual who was 55 years old in 1980 ". This, in addition to being a confirmation of the general aging of the population, also sheds light on another aspect linked to longevity: the well-being.

Well-being is an indicator of an individual's quality of life and a series of internal and external parameters contribute to its definition: physical, social and economic characteristics by the internal aspects and characteristics of the urban architectural environment by the external ones. Borrowing a term used in biology, we could speak about habitat by including within it all the relationships that are established between internal and external elements, determining internal qualities, external qualities and social qualities (Tacchi, 1995). Well-being must be sought and changed with the passage of time: the registry age, in fact, marks the boundary between one class of needs and another. The class of needs reflects on the choices that concern the sphere of living: an over 65 person will have more time to spend at home and less need for a large house; at the same time, however, it seeks the best possible accommodation conditions. In addition to having a very low coefficient of use – an over 65 is living alone or with a partner - a large house in terms of surface area also has higher maintenance costs and more housework to do. So here is a choice: move in search of a new accommodation or improve the conditions of the current accommodation? The choice is not easy and does not always and only depend on a condition of "will".

1. A SPECIAL POINT OF VIEW: THE ACTIVE AGING

The theme of residential construction connected to the needs of senior users has been the subject of numerous insights in literature; given the complexity of the topic, it is unthinkable to carry out an all-encompassing synthesis of the many facets that we have tried to analyze, but we can try to systematize the knowledge acquired to enrich an approach, in certain cases immature, that can be spent on new strategies . Thus, a sort of latent debate is fueled between the design disciplines, as regards the physical and technical aspects concerning the possibilities of using spaces, and the human sciences in a broad sense (Tacchi, 1995). If on the one hand talking about residence means investigating an area with which we all deal daily, on the other hand talking about residence for specific types of users - senior - activates a series of considerations involving apparently collateral disciplines such as gerontology and medicine, in addition to sociology and anthropology. A decisive role was certainly played by the greater trust in prevention campaigns, the search for greater well-being, a more conscious diet and the progress of socio-cultural conditions. The social factor is decisive and must also be considered in the light of another factor, the state of health: it depends on the level of autonomy - or ability to perform daily actions without the help of another person. If it is natural that the level of autonomy can follow a decreasing course over the years and is sometimes inevitable, it is desirable to maintain the state of self-sufficiency – partial or total – in spite of non-self-sufficiency. Here comes a concept that establishes the first focus of the theme: the active aging. Already in the late 90's the World Health Organization had introduced a positive

concept of healthy and active aging defining it as "a process that allows individuals to realize their potential for physical, social and mental well-being through the whole course. existence and taking an active part in society, while providing them with protection, security and adequate care when they need assistance"[2]. Active aging depends on various factors: material conditions and also social elements that individually influence the behavior and feelings of individuals. The interactions of these factors influence how a person ages; many aspects of the urban environment and facilities reflect these factors are included in the structure of an inclusive city. This concept introduces the second focus: the environment, that is, everything that surrounds the individual over 65 from the micro scale - accommodation - to the macro scale - territory. It is appropriate to reflect on accommodation: generally the building heritage is "created" and made functional especially for young people - new and potential buyers - while the elderly, not finding the answer to their needs, have only solutions, if there are limitations to everyday life, of moving towards sons or to social welfare structures which, in the case of elderly accelerate the aging process (Morena, 2013). This has resulted in a reinterpretation of aging in place by long-term care and the elderly housing industry: the latest result of this reinterpretation is the emergence of different residential forms that offer facilities and assistance to people more elderly so that they can live in an environment of their "supported" knowledge (Frank, 2002). In this sense, barrier free interventions and user friendly interfaces at the basis of AAL - Ambient Assisted Living technologies play a fundamental role: they present themselves as a technological infrastructure integrated into the built environment with the main purpose of helping without invading. "A rethinking of the relationships between the elderly and their home is underway, made of targeted interventions that respect the consolidated habits of the user but which, at the same time, can be supportive in daily life" (Nobili, 2019). An ad hoc technology that brings together the various devices and sensors installed in a domestic environment - IOT - can become a potential sustainable solution. "The added value of the new systems lies in the ability to store and process data on domestic activities by collecting information on abnormal changes in the routine for identifying sensitive changes in behaviors that can be interpreted as a signal of prevention (Falasca, 2019). The attention given to the senior user for accommodation, in light of the considerations on active aging, are ineffective if the intervention is not included in a wider system that affects the city itself, the neighborhood or the block. Not so much the inclusion of the senior category in the territory, but its non-exclusion becomes the real mission of the social residence for the elderly. The same urban regeneration should start from this: the urban voids, the degraded places in which it intervenes are places where a community has suffered lacerations that must be mended. Urban regeneration policies involve local communities allowing the collective forces to converge in the realization of shared projects to answer to real needs of the social groups: it allows the improvement of the living conditions "of the inhabitants "living in uncomfortable situations, guaranteeing everyone an equitable condition of social cohesion"(Garsia, 2005). The feeling of belonging to a community is fundamental for social senior housing interventions not only within the individual building, but above all in the relationships that are established between the individual building and the buildings around, between the single building and the commercial activities present and between the single building and the mobility network. At the base, the desire to create a relationship network between the inhabitants should be maintained and nourished: the non-exclusion

[2] The translation was reported by the document "Active Aging . A policy framework", World Health Organization, 2002.

of senior users who choose the aging in place option is therefore punishable if its presence is foreseen within larger projects that have as their mission the "grounding in the community and the home as a place of stability and continuity" (Morena, 2013).

2. TAKING ACTIONS FOR THE SENIOR: STRATEGIES AND POLICIES

To reinforce the considerations just proposed on the issue of active aging and on the aging in place strategy, there are a series of measures in Europe aimed at protecting the senior category through residential and home-based experiments. The aging is connected not only at the age of the individual and to their needs, but also includes the relationships of individuals with external factors. If the main mission of active aging is to maintain an adequate level of independence of the individual for as long as possible, then the field of application of senior housing, understood as the main intervention strategy for the application of this principle, it will concern individuals who are still self-sufficient or partially self-sufficient. If this distinction operates on a biological level, it is necessary to make some considerations also on two other limits to deal with: social fragility and economic fragility. Social fragility derives mainly from a consumerist cultural concept that leads to seeing the elderly as a product that, being unable to offer 100% of its resources, is unknowingly isolated from society. As regards economic fragility pension systems and welfare policies play a fundamental role. All these aspects are in consideration within the strategies in Europe aimed at the realization of senior housing interventions which, for the important social impact, we will call as "social senior housing" interventions. The overview of the strategies will concern some European countries and will serve to return an updated picture of the dynamics in progress but also to deepen their strengths. Even if each strategy must be seen in the reality to which it refers, their set can be considerate as a horizon to strive and overcome to improve and implement the needs-performance approach for senior users. The strategies identified for the senior users self-sufficient, can be summarized in the following residential models: multigenerational homes, residences with facilities, social housing. Multigenerational residences provide for the cohabitation, in the same building complex or district, of people belonging to different age classes: the most widespread generational combinations are those that involve the cohabitation of elderly and students. These types of residences build a network between young and old made up of relationships and assistance with the aim of promoting common activities and promoting mutual support and learning. The model is widespread in several European countries including Belgium, France and Germany. For Belgium and France, the promotion of the model by associations deserves attention instead for Germany the phenomenon must be seen within a more complex system such as that of the funding program, born in 2006 and taken up in 2017, of the German Federal Ministry for the family, the elderly, women and youth with the goals of intergenerational work, voluntary involvement and social assistance at local level. The broad scope of the program provides for financing through an integrated system of European, national and municipal funds for the construction of the Mehgenerationenhauser, homes dedicated to users of different age groups. In France it is also spread the residential model of the RSS - Résidence Service Senior - senior housing for self-sufficient people with facilities in support of daily life. This type of residence, though it will develop a standardized housing model - multifunctional building consisting of residential units and community spaces - can be implemented with superstructures customized services, which can be distinguished in three types:

basic facilities, supplementary facilities and à la carte facilities. An innovative residential format, which diversification is based on the quantity and type of facilities offered and the size and type of housing, which have aroused the interest of many operators managers of real estate: Domytis and Cogedim, as for example. Despite the specificity declared for the senior target, we are faced with residences that do not differ, both from a functional and formal point of view, from ordinary homes; a trait that distinguishes them from all those residential forms designed for the elderly with heavy medical-health incursions. In Europe, alongside the RSS, there are also the so-called viviendas dotacionales in Barcelona. The "viviendas dotacionales" for the elderly are hybrid residential complexes (Cocco, Pibiri, 2011) which have facilities for the neighborhood on the ground floor and on the upper levels accommodation living and common areas. The recipients are self-sufficient over 65 users and the access is via social rent plus a supplementary fee for maintenance. These types of achievements are part of larger programs which involve various partners such as: the Consorci Metropolità de l'habitatge and the Agencia de l' habitatge de Catalunya. A decisive role is played above all by the consortia which, through the involvement of specific areas of the metropolitan area of Barcelona, are responsible for enhancing facilities and housing policies, helping to improve and accelerate interventions in terms of housing availability. The product resulting is like the French residence with facilities but with a public management, which lodgings are within the programs vivienda protected from, and are often part of redevelopment projects and urban regeneration. In respect of social housing, there is the case of Italy with the so-called Integrated System of Funds. The integrated fund system (SIF) is one of the lines of the National House Plan[3] which provides for a series of measures aimed at increasing real estate assets to be carried out with the involvement of public and private capital to be allocated to disadvantaged social categories. At national level, the SIF is managed by CDP Investimenti Sgr and is constituted by the Investment Fund for Living (FIA), a fund of funds. The FIA was established by CDPI sgr on October 16 , 2009 with the aim of realizing affordable housing, intended for the so-called "gray belt", i.e. families not able to satisfy their housing needs on the market, but with incomes higher than those. which entitle you to public housing assignments. Being a fund of funds, the FIA also involves local funds which have local stakeholders as co-investors, primarily local banking foundations, but also Regions, Provinces, Municipalities, Cooperatives and private partners. The tendency to invest in the "social" sector has the consequence, together with ethical and social aims of these funds, that the groups are enlarged to include to news as resident students, temporary workers and not last, the elderly. They present themselves as a "house with facilities" in which the medical aspect is reduced or even absent, going only to be configured where the user requests it. The strategies mentioned so far, although different in shape, have the same contents and, above all, have a common goal: to offer a valid alternative to the self-sufficient elderly person that is not a nursing home or a hospital but can contribute to the maintenance of a certain degree of autonomy and independence, in line with the principles of active aging.

3. DISCUSSION AROUND HOUSING

Beyond the *formae habitandi* - single location and multigenerational cohabitation - strategies in place in Europe has as same result a product widely shared and replicated: the residence with facilities. Although with different definitions depending on which country - RSS, Social Housing for the elderly

[3] The national housing plan, also known as "Piano Casa", was created with the aim of "guaranteeing the minimum essential levels of housing needs for the full development of the human person throughout the country".

- the content is the same: all housing forms are constituted by a set of apartments designed and built for the elderly users with a series of facilities - basic or accessories - that can be provided either by the network of inhabitants itself or by external personnel or by a combination of the two figures. The integration of the residence with the facilities must be seen on a double scale: an internal staircase that allows to understand the integration of the facilities with the accommodation itself (INDOOR FACILITIES) and an external staircase that contemplates the system of relations between the residence considered in its complexity - accommodation and facilities - and the territory in which it is located (OUTDOOR FACILITIES). The buildings, in fact, are generally located in central and non-isolated areas connected by urban infrastructures - bus and underground lines - and in areas served by commercial activities and other facilities useful to the person such as post offices and banks.The only differences can be seen in how they are realized and how they are accessed or rented by users; in fact, if for Italy and Spain the issue of the elderly is seen above all from a social point of view, giving priority to situations of past frailty by offering new housing and social inclusion opportunities, in France the RSS seems to have exceeded the limit imposed by the social residences to offer themselves as a semi-hotel service open to all by delegating their offer of facilities to the choice of the individual user. The theme of integration in the territory can be seen as a common trait d'union for the building types present in the countries covered by the following in-depth

PARIS PLAISANCE

- **LOCATION:** Ile de France, France
- **POSITION:** 64 rue des Plantes, Paris
- **USERS:** Over 60 self-sufficient

- **INDOOR FACILITIES:**

RESIDENTIAL FACILITIES:
- Different typology apartments (from studio typology to three room apt.)
- Common rooms, spaces for relationships

BASIC FACILITIES:
- Ordinary maintenance
- Reception
- 24 Hours Assistance

SUPPLEMENTARY FACILITIES:
- Home assistance
- Restaurant
- Personal care (Gym, Hairdresser, Laundry)

OPTIONAL FACILITIES:
- services at the user's request based on specific needs
- Home delivery(Shopping and drug delivery, meal delivery, medical examinations, collection and delivery of linen)

- **OUTDOOR FACILITIES (minimum distance):**

BASIC FACILITIES:
- Food shop - 80 m
- Supermarket - 350 m

HEALTH FACILITIES:

- "Saint Pierre de Montrouge" Church – 650 m

PERSONAL FACILITIES:
- Hairdresser - 280 m
- Beauty Salon - 300 m

MOBILITY FACILITIES:
- Bus stop - 30 m

Figure 1. Case study in France, specific features to understand the integration in the neighborhood

analysis with reference to: the RSS in France, the interventions in northern Italy for housing for the elderly and programs of redevelopment that contemplate the dotacionales viviendas in Barcelona. The characteristics of the RSS[4] , among those considered as object of study, can be summarized as follows and they can be found in the specific table above (Fig. 1):

• They are large residential complexes made up of no less than 100 apartments, of varying sizes, with typologies ranging from one-room apartments to three-room apartments;

• On average 10% of the total consistency of the useful surface is destined to areas for common activities;

• The monthly fee depends on the location, while the facilities remain unchanged: rental tax, concierge service, internet connection, telephony, free access to areas for common activities;

• The offer of facilities can be expanded with the activation of optional packages created specifically for specific needs.

In Italy, with the variety of building types and housing models, the real social and economic challenge of this sector seems to address the infrastructures of the facilities useful both to the recipients of the accommodation and to the settlement fabric in which they are inserted. What is often underlined[5] and emphasized in the social housing interventions aimed "also" at the elderly is the desire to create a network of relationships between the inhabitants - end users of housing facilities - to strengthen their belonging to a community. Although contextualized to the context to which they

POLO FRASSONI

- **LOCATION:** Lecco, Italy
- **POSITION:** Via Gorizia 2
- **USERS:** Over 65 self-sufficient or partial

- **INDOOR FACILITIES:**

RESIDENTIAL FACILITIES:
- Sheltered housing (A.P.A.) (from studio typology to three room apt.)
- Common rooms, spaces for relationships

BASIC FACILITIES:
- Ordinary maintenance
- Accomodation cleaning
- 24 Hours Assistance
- Social health Operator
- Night assistance

SUPPLEMENTARY FACILITIES:
- Medical health care
- Social assistance

OPTIONAL FACILITIES:
- Daily meals
- Single meal
- Laundry

- **OUTDOOR FACILITIES (minimum distance):**

BASIC FACILITIES:
- Fruit shop - 800 m
- Supermarket - 850 m
- Bakery - 950 m
- Households items - 650 m

HEALTH FACILITIES:
- Pharmacy - 750 m

- "Cenacolo francescano" Theater – 850 m
- "San Francesco" Church – 800 m

PERSONAL FACILITIES:
- Hairdresser - 800 m

MOBILITY FACILITIES:
- Bus stop - 30 m

Figure 2. Case study in Italy, specific features to understand the integration in the neighborhood

[4] The study was conducted on a series of residences proposed by Domytis for the elderly; 10 of them are distributed in 3 regions of France - Ile de France, Nouvelle - Aquitaine, Provence - Alpes- Côte d Azur and Bretagne.

[5] The Social Housing Foundation operates throughout Italy, having activated a network of collaborations ranging from Cassa Depositi e Prestiti. Among the projects that have been studied: Borgo Sostenibile (Milan), Co-housing for the elderly (Milan and the Polo Fondazione Frassoni (Lecco).

refer, some common features can be fount in the table above (Fig. 2) and they can also be stated:

• The residential complexes have modest dimensions in terms of buildings with an average of 18 accommodations;

• Each building has spaces for internal and external common activities and integrated day centers also open to the inhabitants of the neighborhood;

• Accessibility to housing occurs through inclusion in specific rankings that refer to the municipal body, in particular to welfare and social policies, and which provide for the provision of a controlled rent that also includes the portion of facilities, internal to the 'building, available to users;

• the Social Manager has the role of Property Facility Manager, who takes care of the general management of the complex even its maintenance. The roommates also have the possibility of being able to take advantage of home facilities such as nursing care, home shopping and accompaniment for leaving, according to their needs and in ways that will be defined within the same form of housing.

The Municipality of Barcelona, in order to respond to the demand for public residential construction, allows to create, in areas destined for facilities, minimum housing at a calm rent for elderly over 65[6]. Among the characteristics of these complexes and the insight above on the specific table (Fig. 3):

Figure 3. Case study in Spain, specific features to understand the integration in the neighborhood

[6] The viviendas dotacionales are houses with useful facilities both for the inhabitants of housing and for the inhabitants of the neighborhoods. Among the projects being studied in Barcelona: the EMBT study in the Ribera, by Joan Callis and Pia Wortham in the northern suburbs of Barcelona and Sergi Serrat in the east of the La Clota park in Barcelona .

• Residential buildings have a significant impact from the point of view of population density with an average of 65 dwellings;
• The complexes have community spaces useful for the daily life of users where it is possible to take advantage of facilities such as: laundries, meeting rooms, multipurpose rooms and libraries;
• The buildings have a strong "integrative" character since their own access takes place from public spaces - a market, a square - to underline the strong inclusive character of the intervention;
• The facilities to users of the " viviendas dotacionales " are managed directly by the municipal social facilities, which deal with the cleaning of the accommodation and their ordinary and extraordinary maintenance.

While there are common points in terms of building typology - the integration of housing with facilities is a transversal and replicable model in different realities - the substantial difference between the building products is generated in the target audience of the recipients to whom these residences are intended. This consideration poses a simple but not obvious question for three similar cultural realities to which it refers: can the over 65s be considered a "personal" or "social" category?

CONCLUSION

It is impossible to give a sure answer to this question: first of all because positioning oneself on one or the other answer would mean refuting all the premises that have been made on the elderly category, second because it would only serve to fragment a current problem which can be to give an answer only through the systematization of knowledge and experiences so far. If it is true that European societies will have to live with the aging process of the population, even if there be a stationary aging, everything would end from the quantitative point of view but not from the quality. This is demonstrated by the rise in the investment trend and the strengthening of its link with the real needs associated with the natural course of life: "[...] an important aspect that the process of implementing new residential forms will have to therefore taking into consideration will be to prevent the consequences of aging in order to lengthen self-sufficiency as much as possible"(Bologna, Sichi , 2018). The achievements in the Senior Housing sector due to the greater attention to a growing social category are increasingly in line with the principles of active aging and seem to aim, for self-sufficient or partially such users, to offer more and more housing solutions customized to the specific needs of the user. The fact of having identified a model common to different experiences in the European panorama constituted by the union of housing with common facilities and supplementary facilities suggests a precise will of the policies in place: to offer, as a basic, a functional model to the needs of individuals that points to the prolonging independence by fighting isolation and loneliness and providing the possibility of integrating this solution with additional case by case facilities. All attention revolves around the senior user and his needs to be met through the performance of the habitat in which it will be inserted: the policies in support of these actions are therefore presented as tools to achieve this goal making the question on the their social or personal characterization. If the characterization is secondary, their presence within the same process is certainly of primary importance: in fact we have seen, especially in the Italian and Spanish cases, that the inclusion of Senior Housing projects in specific programs for housing leads to specialized paths from which, with the involvement of all operators, quality and functional products can be obtained. The implementation of these programs should converge on the transversal inclusion of public authorities and economic operators, as well as other specialized figures: "Greater

possible synergies between the private and private-social sector to improve the housing conditions of the elderly through territorial planning, housing construction and financial support for the less well off "(Tacchi, 1995). An entire system tailored to the target of the recipients that it is desirable to include in a welfare program that take actions in urban regeneration, to obtain results centered on the need to give concrete answers to real needs. The urban context, place of such actions, should not be underestimated: the same realities in which they will be inserted can themselves be instruments of social, urban and economic reconnection. If the objective to aim for is clear then the strategies that can be pursued become multiple and aimed at creating flexible housing forms that affect both the design choices and the forms of management of housing mobility (Morena, 2013). Connected to a dynamic society that tends to aging, these, over time, may continue to make substantial changes in all relevant sectors: housing policies, the regulatory body, the operators involved, the selection of criteria for selecting interventions, the extension of the framework of design-architectural choices and, last but not least, the inclusion of new forms of residential accommodation among the rental opportunities based more and more on social inclusion and the generational mixing.

PAPER #8.16

RE-VIEWING REFUGEE SPACES: THE CASE OF MARDIN, TURKEY

Neslihan Dostoglu[a], Merve Güleryüz Çohadar[a]
[a]İstanbul Kültür University, İstanbul, Turkey

ABSTRACT

At present, over 70 million people are displaced by war and conflict worldwide. Unfortunately, this number has increased sharply because of the war in Syria. Since March 2011, which is the date when the civil war in Syria started, more than 13 million people have fled from their homes in Syria, with 6.6 million becoming refugees in other countries.
While many countries in the world receive an increasing number of refugees, the spatial practice related with hosting refugees on the move and in various forms of habitation has found diverse, new and improvised forms. These forms reflect a vast landscape of negotiating spatial practice along formal regulations, informal initiatives, enforced policies and spatial exploitations.
Turkey is the country, which hosts the biggest Syrian refugee population in the world. According to official records, there are approximately 4 million Syrian refugees living in Turkey in 2019. 26 camps have been constructed in various cities in Turkey in this process; however, only 1.8 % of the Syrian refugees have resided in these camps, the real problem being related with the "urban refugees" who live outside these camps. In fact, as of 2020 only 7 camps have remained in 5 cities in south-eastern and southern regions of Turkey. (goc.gov.tr)
In this atmosphere full of dilemmas, the diverse reinterpretations of values of belonging and attachment have to be negotiated, and architecture, planning and other related fields need to challenge both the ongoing praxis and take part in shaping the premises within the socio-spatial context for a growing refugee-originated population. The aim of this paper is to re-view the refugee spaces in Turkey, taking the case of Mardin in southeast Turkey as an example, and to re-think the functions related to shelter, site and settlements in crisis responses.

KEYWORDS

Refugee; asylum seeker; physical environment; Turkey; mardin.

INTRODUCTION

> "We're just living on the edge of life. We're always nervous, we're always afraid..."
> Mariam Akash, mother-of-nine, whose husband was killed by a sniper in Syria

Refugee problems, related to having to flee from the country of origin because of the fear of persecution, conflict or generalized violence for reasons of race, religion, nationality or membership of a particular social group, have been a concern for the whole world for a long time. Displacement is even a wider problem, because this comprises also the process of having to flee to different parts of the same country. At present, over 70 million people are displaced by war and conflict worldwide, 58% of which are internally displaced (migrationdataportal.org). Unfortunately, this number has increased sharply because of the war in Syria. Since March 2011, which is the date when the civil war in Syria started, more than 13 million people have fled from their homes in Syria, with 6.6 million becoming refugees in other countries.
Turkey is the country that hosts the biggest Syrian refugee population in the world. According to official records, there are 3.585.198 Syrian refugees living in Turkey in 2020 (goc.gov.tr) Since 2011, the year

when massive migration from Syria started, 26 camps have been constructed in various cities in Turkey, where basic services such as education and health have been met. However, only approximately 1,8% of the Syrian refugees have lived in these camps, and the real problem has been with those "urban refugees" who live outside these camps (Erdoğan, 2019). Since the refugees have preferred to live in urban areas, only 7 camps have been left in 5 cities in Turkey at present (goc.gov.tr).

As the refugee crisis is affecting the whole world, the actions taken by the refugees, authorities, the public and private stakeholders need to be understood within a broader field of spatial discourse. In fact, architecture, planning, and other related fields need to challenge both the ongoing praxis and take part in shaping the premises for the future accommodation of a growing refugee-originated population. Because of the new contextual challenges, the architectural profession has to re-think the functions related to shelter, site and settlements in crisis responses. In many studies on migration and integration of refugees in their new destination, it is mentioned that the most important challenges faced by the immigrants (refugees) are related with the sense of belonging and identity. The refugees' problems are rarely considered in the context of spatial issues. Therefore, the intention of this paper is to reach a general framework that highlights the shelter/spatial/housing problems faced by refugees in urban areas (outside of the camps) based on a case study carried out in Mardin,Turkey in 2019.

This paper aims to investigate the conditions of urban refugees who live outside the camps and the spatial problems that the refugees face in their daily lives. The paper starts with a general background about the migration process of Syrians, and its influences on the whole world, especially in Turkey. Then six refugee houses in Mardin, Turkey are evaluated as case studies. Finally, findings of the field study and interviews are summarized and a general framework is provided for evaluating the spatial problems of refugees in Turkey.

1. HISTORY OF THE REFUGEE CRISIS IN SYRIA

The 1951 Refugee Convention spells out that a refugee is someone who "owing to a well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion, is outside the country of his nationality, and is unable to, or owing to such fear, is unwilling to avail himself of the protection of that country." (UN General Assembly, 1951)

Syria's civil war is the worst humanitarian crisis of our time. Half the country's pre-war population, i.e. 13 million people, have been forced to flee their homes, and approximately 400,000 Syrians have lost their lives in nine years of armed conflict, which began with anti-government protests before escalating into a full-scale civil war. (france24.com)

Anti-government demonstrations began in Syria in March of 2011, as part of the Arab Spring. Pro-democracy protests erupted in March 2011 in the southern city of Deraa after the arrest and torture of some teenagers who painted revolutionary slogans on a school wall. After security forces opened fire on demonstrators, killing several, more took to the streets. The unrest triggered nationwide protests demanding President Assad's resignation. The government's use of force to crush the dissent merely hardened the protesters' resolve. By July 2011, hundreds of thousands were on the streets across the country. Thus, in a few months, army defectors had loosely organized the Free Syrian Army and many civilian Syrians had taken up arms to join the opposition. Divisions between secular and Islamist fighters, and between ethnic groups, continue to complicate the politics of the conflict.

Families have struggled to survive inside Syria or make a new home in neighboring

countries. Others have risked their lives on the way to Europe, hoping to find acceptance and opportunity. And harsh weather conditions make the life of a refugee even more difficult. At times, the effects of the conflict can seem overwhelming, leading into the destruction of even World Heritage Sites, such as Palmyra (Figure 1) (Figure 2).

1.1.The situation of Syrians caught in the war

More than four million Syrians have registered or are awaiting registration with the United Nations High Commission of Refugees, that leads the regional emergency response. There has been an immense growth in the number of refugees since the beginning of the conflict. In 2012, there were 100,000 refugees. By April 2013, there were 800,000, which doubled to 1.6 million in less than four months. There are now 6.6 million Syrians scattered throughout the region, making them the world's largest refugee population under the United Nations' mandate. This situation is considered as the worst exodus since the Rwandan genocide in 1994.

According to the United Nations, more than half of all Syrian refugees are under the age of 18. Most have been out of school for months. The youngest refugees face an uncertain future. Some schools in various countries have been able to divide the school day into two shifts and make room for more Syrian students. But there is simply not enough space for all the children, and many families cannot afford the transportation to get their children to school. The youngest are confused by their experiences, lacking the sense of safety and home they need. The older children are forced to grow up too fast, finding work and taking care of their family in desperate circumstances (unhrc.org).

Many Syrian refugees have fled across the border into Turkey, overwhelming urban host communities and creating new cultural tensions. However, there are also Syrian refugees living in Jordan and Lebanon, which are the region's two smallest countries, with weak infrastructure and limited resources. There are also many Syrian refugees in Iraq, in addition to 6.7 million internally displaced Iraqis.

Hundreds of thousands of refugees have also attempted the dangerous trip across the Mediterranean Sea from Turkey to Greece, hoping to find a better future in Europe. Not

all of them make it across alive. Those who do make it to Greece still face many challenges — resources are strained by the influx and services are minimal.

1.2. Means of escape from Syria

Thousands of Syrians have fled from their country since 2011 (Figure 3). People often decide to finally escape after seeing their neighborhoods bombed or family members killed. Most of them have fled to neighboring Turkey, Lebanon, Jordan, and Iraq while thousands also end up in more distant countries of the Caucus, the Persian Gulf, North Africa and Europe. The risks on the journey to the border can be as high as staying in Syria, i.e. families walking for miles through the night to avoid being shot at by snipers or being caught by soldiers who will kidnap young men to fight for the government.

Figure 3. A photo from the days when thousands of Syrians have fled from Syria. Source: (https://www.aljazeera.com/news/2018/03/eastern-ghouta-exodus-largest-syria-year-war-180316053942233.html)

2. THE SITUATION OF SYRIAN ASYLUM SEEKERS IN TURKEY

The Syrian refugee crisis arose as the Turkish government was in the midst of overhauling its immigration system to meet international—and, particularly, European Union—standards. The implementation of these reforms has limited Turkish authorities' capacity to manage the Syrian inflows, and as a result, management of the crisis was left largely in the hands of national organizations working on the ground, in camps, without larger policy guidance. Meanwhile, formal immigration channels, including recognition of refugee status, remain restricted to Europeans, while non-Europeans receive temporary protection status and are expected at some point to resettle in a third country.

The difficulty of sheltering the world's largest refugee population is reflected in Turkey, whose open door policy to refugees for a long period of time, shields European nations from a migration crisis far worse than the one they are struggling with now. As some European governments turn to police and barricades to stem the flow of migrants, Turkey has continued accommodating almost 4 million people from its war-torn southern neighbors.

Turkey is the country which hosts the biggest refugee population in the world. As authorities from the Migration and Politics Research Center in Hacettepe University remark, the Turkish society approaches the Syrians in a much more positive way than any other country in the world and the social acceptance level of the Syrians is much higher. Of course, people in Istanbul, where approximately 550.000 Syrians live, complain about the Syrian beggars, however there are many more Syrians in Istanbul, and people are not aware of them. When the war first broke out in Syria in 2011, Turkey believed tens of thousands would cross its 900-km (560-mile) frontier. Since then, fighting has engulfed the country and Islamic State militants have exploited the chaos to impose brutal, medieval-style rule across large parts of both Syria and Iraq. According to the Turkish authorities, approximately 40 billion dollars have been spent on humanitarian responses, which includes some of the best equipped refugee camps, including schooling, healthcare and social services.

Turkey has implemented an "open door policy" since the beginning of the Syrian crisis, and has not rejected the Syrians who want to come

to Turkey. However, they are not accepted as refugees, but rather as asylum seekers under the heading temporary protection, which does not cover the natural rights of refugees. This situation has caused the Syrians in Turkey to be without any status.

In fact, while Turkey provides for the basic rights of Syrians, they do not have the right to work legally in Turkey in general, even if they are educated. Although the government has decided to allow employment for Syrians, upto 10% of the total number of employees in a work place, thousands of Syrian refugees work illegally in the Turkish garment industry where child labor, low wages and poor conditions are common. Syrians also have problems related with education, although the Ministry of Education in Turkey tries to resolve this issue.

The Syrians are not sure how long they will be allowed to stay in Turkey according to the temporary protection status. Proposals such as sending the refugees to a secure region to be established in northern Syria does not convince the Syrians because of cases such as Srebrenitsa in Bosnia-Herzogevina, where 8000 people were killed in 1995, even though it was declared to be a secure region by the United Nations Security Council.

The government of Turkey has spent more than 40 billion dollars for the refugees in the last nine years. On the other hand, the support that has arrived from international community is much less. The European Union has offered money to the Turkish government in return for keeping the refugees in Turkey, but this cannot be considered as ethical because this load is not only financial, but also has political and social risks. The European Union has to develop a joint migration and refugee policy with Turkey, which plays a key role in this process. Actually, the present situation cannot last long. If European Union closes its doors to the refugees, or tries to prevent them from leaving Turkey, the number of refugees will increase in Turkey.

Turkey is considered by many refugees as a transit country. However, this is a difficult situation for a country because this means that it functions as a bridge, and yet only 10% of the refugees go to other countries, while 90% stay. Since the possibility of passing through gives people the hope of going to other countries, more refugees arrive, increasing the number of refugees.

In 2017, AFAD conducted a field study about the demographic views, life conditions and future expectations of Syrians in Turkey. In the report of the field study, there are comments about when and under what conditions Syrian refugees will return to Syria. According to the results, approximately 22 percent of refugees in the camps and about 16 percent of refugees outside the camps never consider returning back to Syria (AFAD, 2017).

In Turkey, Syrian refugees are settled densely in certain cities. It can be seen in Figure 4, that there are ten cities which refugees have generally chosen to settle. Most of these cities are at the Syrian border of Turkey (goc.gov.tr).

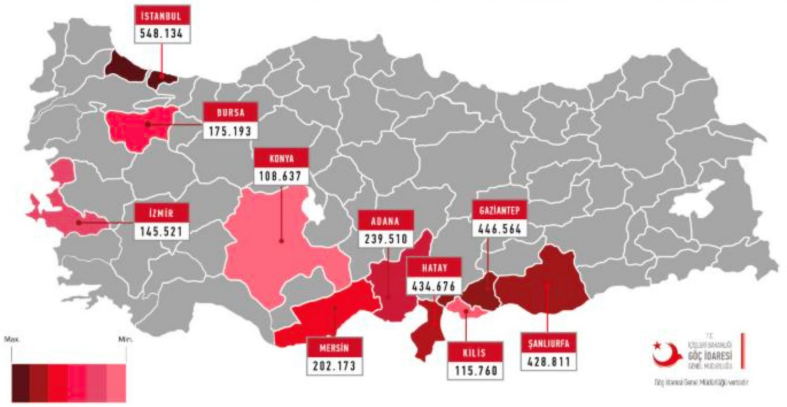

Figure 4. Distribution of Syrian refugees by provinces in mid July 2020, Turkey Immigration Department. Source: (https://www.goc.gov.tr/gecici-koruma5638)

2.1. Life in camps

Some of the refugees continue living in camps. Jordan's Za'atari, the first official refugee camp that opened in July 2012, gets the most news coverage because it is the destination for newly arrived refugees. It is also the most concentrated settlement of refugees: 76,143 Syrians live in Za'atari, making it one of the country's largest cities (UNHCR Za'atari Camp Fact Sheet, 2020). The formerly barren desert is crowded with acres of white tents, makeshift shops along the "main street", sports fields and schools for children.

A new camp, Azraq, was opened in Jordan in April 2014, carefully designed to provide a sense of community and security, with steel caravans instead of tents, a camp supermarket, and organized "streets" and "villages." It hosts 36,785 Syrian refugees at present (UNHCR Azraq Camp Fact Sheet, 2020).

Iraq has set up a few camps to house the influx of refugees who arrived in 2013, but the majority of families live in urban areas. In Lebanon, the government has no official camps for refugees, so families have established makeshift camps or find shelter in the derelict, abandoned buildings.

In Turkey, there is an acceptance that, although inconvenient, Turkey must help its neighbor. 26 camps where basic services such as education and health were met, were constructed in various cities in Turkey, especially in border cities, receiving positive comments from the United Nations Development Program (Figure 5). At present, however, there are only 7 camps in 5 cities (Hatay (3), Kilis (1), Adana (1), Osmaniye (1)) in Turkey, since most refugees prefer to live outside the camps (goc.gov.tr).

Although the refugees who live in the camps are considered as needy, the living conditions of the refugee camps coordinated by AFAD were praised according to a report published in The New York Times on Feb. 13, 2014. The Öncüpınar Camp in Kilis province, a camp where 2,053 shipping containers have been converted into housing units, was particularly commended in the report. It was described as "clean," unlike many other refugee camps in the world, and the residents of the camp thanked the Turkish authorities (Hutzler,

2014). On the other hand, some researchers argue that better living conditions could be provided for refugees living elsewhere in the country with some of the funds spent on such camps. The legal status of the refugees is one of the most problematic issues in Turkey. Turkey has become a party to the Geneva Agreement of 1951 with geographical limitations, as a result of which Turkey can give the refugee status only to those coming from Europe, which means that the migrants from Syria are considered as asylum seekers, and not as refugees.

Figure 5. Temporary Shelter Center in Gaziantep/ Syrian Refugee Camp in Gaziantep. Source: (http://www.referansgazetesi.com.tr/haber/gaziantepten-23-bin-suriyeli-yolcu-haberi-32439.html)

2.2. Life outside the camps

Some Syrians know people in neighboring countries, who can open their houses to them. But many host families are already struggling on meager incomes and do not have the room or finances to help as the crisis drags on. Thus, refugees find shelter wherever they can. Families live in rooms with no heat or running water, in abandoned chicken coops and storage sheds. Most refugees must find a way to pay rent, even for derelict structures. Without any legal way to work in Turkey, Jordan or Lebanon, they struggle to find odd jobs and accept low wages that often don't cover their most basic needs. And language is a barrier in some countries, such as Turkey.

The lack of clean water and sanitation in crowded, makeshift settlements is an urgent concern. Diseases like covid-19, cholera and polio can easily spread, becoming more life-threatening without enough medical services. In some areas with the largest refugee populations, water shortages have reached emergency levels; the supply is as low as 30 litres per person per day — one-tenth of what the average American uses.

In Turkey, the majority of refugees have tried to survive and find work in urban communities, despite the language barrier. In fact, according to research findings, only 1.8% of the Syrian refugees live in the camps in Turkey (Erdoğan, 2019). The biggest difficulty of refugees living outside the camps is accommodation because these people cannot find the necessary money to pay their rent. The second major difficulty is finding employment. The legal status of the refugees is another problematic issue.

Based on the authors' research, it has been hypothesized that if the destination has a common language, common religion and similar cultural identity like refugees, immigrants (refugees) do not face problems such as belonging and sense of identity. In order to verify this argument, the city of Mardin in Turkey was chosen as the field study because the city is located on the Syrian border, with a similar cultural background as Syria. Furthermore, the majority of the inhabitants living in Mardin adopt the same religion and speak the same language as a second language (Arabic, Kurdish). However, it has been found out that, despite this socio-cultural resemblance, Syrian refugees in Mardin still face many problems, especially in relation to housing (shelter) issues.

3. THE CASE STUDIES IN MARDİN OLD CITY CENTER

Mardin is located on the border of Turkey and Syria, in southeast Turkey. Mardin city center

area (landscape) is a candidate for UNESCO World Heritage List since the city's landscape and houses have a unique character (Figure 6). Since people from different ethnic origins have lived together in Mardin in tolerance with each other throughout history, Mardin is referred to as 'the city of tolerance' in many publications.

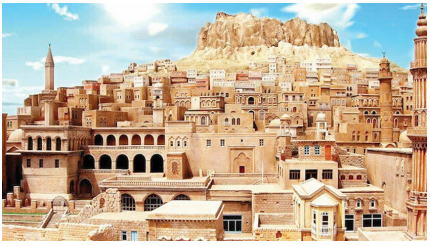

Figure 6. Mardin Landscape General View. Source: (https://www.farmasi.web.tr/farmasi-mardin/)

After the recent Syrian Civil War erupted in 2011, due to the geographic proximity and cultural similarity, a huge number of Syrian refugees have chosen to live in Mardin. According to official documents, the number of Syrian refugees living and working in Mardin in 2018, was 92.971 (goc.gov.tr). The Syrian refugees have settled mainly in two districts in Mardin, i.e. Artuklu and Kızıltepe. Since the authors have decided to concentrate on the shelter problems of refugees with low socio-economic conditions, Artuklu was chosen for the pilot study, because the district consists of the old city center where the house rents are relatively cheaper than other districts of Mardin. The city center of Mardin has been the heart of economic activity and social relations since the establishment of the city. In addition to its economic importance and owing to its place in the collective memory of the city, this district has conserved its aesthetic and social values. Besides, because it has a pedestrian area that is not suitable for vehicular traffic, this district is one of the city's most attractive public places for both inhabitants and tourists. In spite of this fact, inhabitants of Mardin generally do not prefer to live in this district. In accordance with these preferences, apartment blocks started to rise on the outskirts of the historical city center in the 1990s. At present, the majority of inhabitants have chosen the new settlement called Yenişehir (which means New City) to live. These developments have caused a demographical change in Mardin. Muslim Arab or Armenian and Syrian Christian families have vacated the area, while other ethnic groups (Kurds and Arabs) who come from villages have settled in the city center (Küçük, 2013). After 2011, the Syrian refugees have caused another demographic change. All of these developments have also led to social/cultural transformations in the city of Mardin. Refugees have been spatially clustered in some neighborhoods of Mardin old city district. For this paper, six houses of refugee families, that are located in these different neighborhoods, were chosen to be examined as case studies, as a pilot study. We expect to continue our research including other houses of refugee families in the future, to get a better understanding of the situation.

3.1. Spatial dimensions of the case studies

As mentioned above, the city center of Mardin was chosen as an area for conducting a pilot study that sought knowledge about the housing problems of Syrian refugees with low socio-economic status. The study focuses on Syrian refugees with poor economic condition since it is obvious that this group would have more problems related with shelter and living in their new surroundings than the refugees with high socio-economic situation. In this pilot study, structured face to face interviews were carried out in the houses of these families in the historical area (inner city) of Mardin, detailed photographs were taken to document each house, and sketches were made in relation to the plans of the refugees' new houses in Mardin and the old houses that they used to live in Syria. The sketches of the

old houses of refugees were drawn without scale in interviews, according to the refugees' explanations. Thirty questions related with the socio-economic, and physical issues were asked to two people in each house (total 12 people). The questions in interviews were about the city of Mardin, their new houses in Mardin, their old cities, and the houses where they used to live in. Below, the sketches and photos of the six refugee households are sorted, the findings of interviews and observations are summarized (Figures 7, 8, 9, 10, 11, 12).

3.2. Evaluation of the case studies

As it has been stated in the introduction, a questionnaire was conducted and observations were made to reflect the current situation, and to evaluate the problems of refugees in Mardin, Turkey. According to observations and interviews, it can be concluded that the physical living conditions of the six visited houses have a lot of problems that prevent the refugees from maintaining their lives in a healthy way.

As a result of this questionnaire, it can be pointed out that the biggest difficulty of refugees living outside camps is accommodation, because these people cannot find the necessary money to pay their rent. The second major difficulty is finding employment. The legal status of the refugees is another problematic issue.

In interviews, a question was asked to understand why the refugees did not choose to live in refugee camps. All respondents answered this question by indicating that they do not want to restrict their freedom. However, they mentioned that living in urban areas has its own difficulties, such as finding affordable housing.

In observations of the field study, especially the inadequacy of the bedroom areas was noticeable. There were no special spaces defined as bedrooms, as 5-6 people slept next to each other in the same room. In fact, in household no 3 there were no additional rooms except the living area. It was seen in the visits of household no 3, that a type of curtain was used to divide the space (living area) and create a special area for bedroom (Figure 9). Household no 2 and 4 had an additional room, but the refugees could not use these rooms since they were not suitable physically, and had heat insulation problems and broken windows (Figure 8) (Figure 10). As seen in the plan sketches, the main rooms of houses were defined as 'living area's, since, these rooms were used as daily living room, main visitors' room, dining room during the day, and as a bedroom during the night. In interviews, all refugees complained about insufficient space of their houses.

Unhealthy conditions were observed in the inadequate plumbing pipes and sanitary systems in the kitchens and bathrooms (Figures 7, 8, 9, 10, 11, 12). As can be clearly seen in the pictures above, there are heat insulation problems in the houses. The respondents said that they do not have the financial means to replace the broken glass with a new one, thus they try to eliminate the transmission of heat to a small extent by pasting cardboard to the broken glass areas. Another physical problem faced by the refugees in their houses is the lack of water insulation and the moisture problem arising from this.

All of the houses that were investigated were discovered to have rent prices lower than other houses in Mardin. In fact, Syrian refugees mentioned the low rent prices as the reason for choosing to live in this area. All respondents mentioned their main problem as 'lack of money'. They emphasized that they will be happier if they have enough money to paint the walls, develop insulation, and repair their houses.

By comparing the old and new houses of the refugees (Figures 7, 8, 9, 10, 11, 12), it was observed that the old houses in Syria have sufficient spaces for all family members. Old houses of the refugees have at least two bedrooms. In fact, some houses even have two living rooms (saloons) (Figures 9, 10). In interviews, the Syrian families explained that there were no unhealthy conditions in their old houses in Syria. Another question in the questionnaire focused on whether they felt like foreigners in Mardin. All respondents answered this question that they do not feel themselves as a foreigner, since the majority in the city speaks the same language and embraces the same religion with them, in addition to the fact that they have many relatives living in Mardin from the times before the war. Previous studies have pointed out

that social networks play a very important role in the immigration process of people (Boyd, 1989; Ritchey, 1976; Elrick, 2005; Elrick and Ciobanu, 2009; Epstein, 2008; Fawcett, 1989; MacDonald and MacDonald, 1964; McKenzie and Rapoport, 2007). In these studies, strong evidence is provided regarding the effects of friends and relatives, networks, on migration flows. It can be said that the Syrian refugees' social networks in Mardin have a facilitator role in their integration process with the city. Although they do not feel as foreigners, they have emphasized the fact that they preferred to communicate with only their relatives and Syrian friends rather than local people.

CONCLUSION: EXPECTATIONS FROM PROFESSIONS RELATED WITH THE BUILT ENVIRONMENT

According to the results of the case studies, there is a strong need for rethinking the refugees' life conditions in the context of physical issues. In general, refugee families that have economically low income, often cluster around poor neighborhoods, and have to live together in small houses under unhealthy conditions. It is obvious that better regulations on rental rates and public housing systems are needed. Currently there are no public housing opportunities besides refugee camps in Turkey. Syrians coming to Turkey, who intend to remain outside the camps, can live in a city where they are registered. Therefore, refugees who choose to live outside of the camps need to provide their housing expenses themselves.

In this context, the expectation from the government is the development of comprehensive policies for integrating the refugees with the society. In fact, it has been nine years since the war started, and there are still hundreds of thousands of children who do not get proper education, and many refugees have to work illegally to sustain their living. Since the government in Turkey expects the refugees to go back after the war is over, no strategic plans are made for the refugees; however, the fact is that most of them will not go back. Because refugees have left their homes and their countries, they have a deep sense of placelessness, making place attachment and sense of belonging the key elements in integrating and connecting them with the city.

In the world, the sheltering problems of refugees are generally tried to be solved by building temporary shelters in isolated camp areas which are located outside the cities. Unfortunately, this approach leads to many problems. Isolated refugees face economic and social problems, while authorities face many problems related with the economic sustainability of the camps. Also, there are some organizations that have a mission to improve the lives of people displaced by force, by providing affordable temporary shelters; however, most of these efforts are not sustainable. To solve refugee problems, people need to find more permanent solutions. Architects, city planners and people from related disciplines should develop designs to contribute to the integration of the refugees with the host country. For instance, there are many unused, idle buildings in cities, which may be transformed into shelters for refugees; in this way both unused buildings can be revitalized and a sustainable solution to refugee housing problems can be provided. Furthermore, refugee housing problems should be seen as a social housing problem of low-income families. Traditional social housing projects mostly are built and sold or rented by governments and local councils. However, there are some alternative approaches to build social housing projects such as incremental housing. Incremental housing can be defined as a gradual step-by-step process whereby building components and parts are improved by owner-builders as money, time, or materials become available. This type of alternative approaches should be considered while planning houses and

settlements for refugees. Future research on these areas should be done in order to create more specific solutions and guidelines for this issue. Our study is a pilot study, and our aim is to make a more comprehensive study by increasing the sample number in the future.

In conclusion, it can be emphasized that the activities of refugees, authorities and the public and private stakeholders need to be understood within a broader field of spatial discourse. The diverse reinterpretations of values of belonging and attachment have to be constantly negotiated, and the architectural, planning and other related fields need to challenge both the ongoing praxis and take part in shaping the premises within the socio-spatial context for a growing refugee-originated population. In this context, institutions related with the architectural profession and architectural education have a responsibility to re-think the functions related to shelter, site and settlements in crisis responses.

CONCLUSION

A RESTLESS, NON-CONFORMIST AND ADAPTIVE DISCIPLINE

Ivan Cabrera i Fausto
Conference Chair
Higher Technical School of Architecure of the Polytecnnic University of Valencia, Spain

Architecture is probably the most pragmatic and adaptive of arts. Undoubtedly this is due to its scientific side. And it is also presumably the most restless and non-conformist science, being that unmistakably connected to its artistic aspect. Simultaneously, the discipline of all those who have devoted their lives to the design and construction of human habitat has frequently become the materialization of human aspirations, values and priorities. A society maybe can lie in many different manners, but its architecture always reveals the truth. Therefore, most likely the pragmatic and adaptive, but also restless and non-conformist research in architecture which we are having nowadays is the best evidence of a society which voluntarily or involuntarily, consciously or unconsciously prioritizes these features and is more demanding than ever.

The long tradition of research in architecture existing in many institutions all over the world has rather recently been complemented by the encouraging of research, also in architecture, in almost any university. However, funding is not proportional to this promotion at all yet, also in architecture once again. While still solving some apparently minor but actually relevant matters such as clearly differentiating research by design and pure research, research in architecture is enjoying the daybreak of what promises to be a fruitful era. The conferences on research in architecture jointly organized by the European Association for Architectural Education and by the Architectural Research Centers Consortium constitute a middle aged venture awaited with enthusiasm every two years by the fellowship of the European and the North American associations. The 2020 edition to be hosted by the Higher Technical School of Architecture of the Polytechnic University of Valencia was announced on May 31, 2019 in Toronto (fig. 1) during the ARCC 2019 International Conference and on August 30, 2019 in Zagreb during the EAAE Annual Event and General Assembly.

Figure 1. Presentation of the EAAE-ARCC International Conference and 2nd VIBRArch in Toronto

The event was received with interest and satisfaction by both the American and European researchers. Some of them were quite familiarized with the Valencia International Biennial of Research in Architecture, best known for its acronym VIBRArch, whose second edition would be merged with the EAAE-ARCC joint venture on this special occasion.

The call for abstracts for both full papers and posters was issued on September 16, 2019 and its deadline was set on November 11, 2019. Having been extended one week two hundred and ninety-five proposals for full papers and posters were received. A Scientific Committee composed by two hundred and fifty people from the five continents and with a remarkable 60,40% percentage of women, reviewed thoroughly of the proposals. Authors were accordingly informed by the end of the year. Accepted abstracts should turn into full papers or posters and be submitted by February 17, 2020. But during this period the coronavirus disease had already started beating the world up and its ferocity would be soon felt from east to west. However uncertainty did not affect at all authors and the percentage of full papers and posters submitted was even higher than in other similar events without such a powerful sanitary interference. Wisely intuited by the leaders of both organizations, travelling would turn into something difficult, dangerous or blamable within days or weeks. Therefore and on March 24, 2020, with Italy, Spain and other European countries already applying home lockdown, the conference was postponed to late fall 2020. The whole calendar of the event was remade adapting it to the new dates and once again the resilience of architecture researchers proved itself. Everybody stuck to the event. Nobody surrendered. After an extremely tough spring, on June 10, 2020, the new dates and a blended modality including the possibility to attend online or face-to-face was announced (fig. 2).

Figure 2. Board announcing the new dates of the EAAE-ARCC International Conference

Full papers and posters had been reviewed by the Scientific Committee during that period. Authors were notified. When lucky, those who had been directly accepted toasted, and those who were required amendments submitted them by September 14, 2020. At the very end, one hundred and fifty-five papers and one poster made their way through and were accepted for presentation during the up to seven parallel sessions. These are the works which have been included in these proceedings distributed in the frequently mentioned eight thematic areas.

The first of these thematic areas was titled "devising, representing and narrating the city". Up to twenty-six papers were finally accepted and presented during the conference. Authors tackled aspects as diverse as the broader perspective and view of the city, its representation and reading, both theoretically and by means of interesting examples in Asia, Europe or America, its geometry, the way in which their relevant assets are inserted and presented, and finally even challenging software and techniques to help analysts and planners.

The second thematic area focused on "living in urban landscapes". Likewise twenty-five papers and one poster had been accepted and, therefore, were given the chance to be presented during the event. Authors dealt with a vast range of topics, but certain areas received a special attention and many papers concurred. It is the case of the simultaneous work with different scales of the city, the relevance of green areas and connection with nature, or the meaning and understanding of representative public spaces and infrastructures.

Being the third thematic area, "the new faces the old" hosted up to twenty-two full papers focusing on the frequent and unavoidable coexistence of new elements in preexisting contexts, frequently with historical value. The contents of this block reveal an undoubted nowadays interest on the adequate knowledge, attitude and cautions for an architect when being commissioned a brand new project in this kind of contexts. Likewise it is also easy to detect a tendency to defuse the confrontation of new architecture with old architecture by accepting that this fact has been constant in the history of cities and a great bunch of good practices can be studied.

"Restoration, conservation and renovation" was the fourth thematic area. Seventeen full papers were accepted and finally presented during the conference. The set of works reveals up to four areas of interest concentration nowadays. The first is a classical one focusing on theories and the adequate previous analysis and data collection. The second one encompasses frequent successful case studies which provide future practitioners a fair set of options about how to tackle future commissions. The third area places value in works which were not considered heritage until recently such as infrastructures, certain historical neighborhoods or rather recent architecture. Finally, researchers specialized in this matter begin to welcome peers which embrace the discipline not from a theoretical, historical or design aspect, but from a purely structural, conditioning or material point of view, establishing occasional bridges to the topics of the fifth thematic area.

This fifth block focused on "a future based on technology". Seventeen full papers succeeded through the different reviews in order to be included in the proceedings and presented in the different parallel sessions. It cannot be denied that sustainability and the measuring and performance of any single parameter connected to it are taking a leading role day after day. Simultaneously, matters such as ventilation, climate comfort and lighting are becoming a relevant welfare parameter nowadays and many researchers are specializing on them. Finally building materials, techniques and structures still keep a meaningful group of academics doing their research on them. However their approach switches increasingly from new constructions to the renewal and preservation of existing ones.

The sixth thematic area was devoted to "smart cities vs. tech cities". The seven full papers finally accepted and presented focused mainly in data collection and analysis in order to make it useful for a variety of aspects involving mobility, energy efficiency or indoor comfort.

The seventh thematic area entailed up to twenty-five full papers focusing on "new professional practices and research practices" which put a special emphasis on the variety of work and research fields which architects have recovered or discovered recently and mostly after the 2007 financial crisis. To start with many papers placed a special value on pure research as a necessary and appropriate job opportunity for architects. Areas of knowledge discussed in other thematic areas were included here as well, such as comfort, sustainability or circular economy. But specific fields such as psychology, sociology, virtual environments and synergies between research and teaching were also presented.

Finally, the eighth and last thematic area focused on "participation processes, diversity and inclusiveness". Up to sixteen full papers were accepted to be in these proceedings and to be presented during the conference. Despite some examples of these trends can be found throughout history, the works presented in this block are devoted to what may be is one of the most genuine phenomena of our time. Peculiarities of public participation were discussed in different contexts and a special focus was placed on the design of urban spaces and buildings for underprivileged groups which historically have received limited attention.

The richness of matters attended is perhaps the first and most obvious conclusion. Architecture has become a huge discipline encompassing many specialist areas and fields of practice which resist being detached from the central core as it happens in other disciplines such as medicine. This diversity is understood in our case as richness and not as a problem. The developing of the conference evinced what is one of the most productive features of architects. We are curious people and we are interested in whatever has something to do in where people live and how people live whatever it is. But this colorful and varied panorama also revealed some patterns which are becoming more and more habitual and could be understood as the key issues of our times regarding research in architecture:

- Transversality is taking the scene. Most of the papers could have been included in more than one thematic area since their topic and approach frequently responded to a transverse and open-minded attitude. The full papers themselves or the fruitful debates developed after the presentations during the parallel sessions placed value on the concurrence of different approaches from different fields of expertise, cultural backgrounds or disciplines. Definitively we do trust in interdisciplinary studies and activities (fig. 3) to safe better results in whatever architecture has to confront or undertake.

- Western countries are almost already and sufficiently built if we consider their current needs. The migration of people to urban areas cannot be denied and obviously involves certain requirements to be attended

by a huge variety of stakeholders were architects must have a decisive role. But frequently maintenance, renewal and fair distribution of assets and resources provide better solutions than brand new expansive plans.

• Futuristic visions get little attention. New designs when innovative are almost always the result of a search for a better comfort, a more sustainable or respectful approach, a holistic understanding of the situation or any other attitude which is the polar opposite to the wish to get the attention exclusively by means of pure novelty.

• Respect is an increasingly often concept and is taking the lead over other factors such as profitability or personal recognition which are understood as unacceptable in many contexts. Respect for our heritage, understanding it not just as the assets with specific, individual and acknowledges artistic value, but as all what we have inherited from previous generations. Respect for everybody, especially for those collectives who have been traditionally disadvantaged or even non-cared, and for those who are still to come. And consequently, respect for the planet, ever more understood as a fragile entity which needs to be understood and protected.

• Care as an active attitude following respect. A meaningful percentage of researchers in architecture are devoting their time to see how they can care any individual of the society depending on their circumstances, or how they can care and heal the environment by means of actions such as circular economy or cooperation.

The work which was got the Best Paper Award during the farewell ceremony is a magnificent evidence of set of values which this conference has revealed as the undeniable sign of the times when it comes to research in architecture and therefore when it comes to what is relevant to nowadays society. Authored by Madlen Simon, University of Maryland (fig. 4); Shaimaa Hameed Hussein, Al-Nahrain University (fig. 5); and Gregory Weaver (fig. 6), University of Maryland; was titled "Designing Better Cities Together: Global inter-university partnership model for architectural education addressing the United Nations 2030 Sustainable Development Goals".

Having foretold the fact that most of the audience would attend the conference by means of the online option, as many segments as possible were scheduled in the European afternoon and evening since American attendees would face obvious and meaningful inconveniences in attending sections arranged during the European morning. Therefore six out of seven scheduled parallel sessions of paper presentations were arranged accordingly and only the last one when just European authors had been included was arranged on the European Saturday morning. For some attendees it happened to be their first online conference and despite the fact that it took a while for many of them to get used to the particularities of Teams® (fig. 7), which was the communication platform chosen for all online segments, debates were extremely fruitful and day after day everybody switched off his or her laptop with the feeling of having learnt important facts, having met interesting people and possible future collaborators, and above all the feeling of being participating in something important, something relevant, something absolutely committed to improve people's lives.

Figure 7. Participants at the online parallel session held at room A on Saturday, November 14, 2020, at 10:00

The success achieved in the nine previous editions of the joint conference – Montreal in 2002, Dublin in 2004, Philadelphia in 2006 and 2018, Copenhagen in 2008, Washington DC in 2010, Milan in 2012, Honolulu in 2014, and Lisbon in 2016 – was achieved once again in Valencia in 2020, being the most convincing argument for all the audience to focus on the next edition to be held in Miami in 2022. Until then we have two years of work in meaningful adverse conditions because of the global health crisis caused by the coronavirus disease. But architects are not only curious as previously mentioned and committed as easily deducible when being observed. Architects are basically optimistic people. Optimism is intrinsic to architectural teaching, practice or research. Nobody decides to become an architect if he or she does not have the wish of improving the world and the conviction of being capable of it through effort and dedication. The variety of tools available nowadays, the boundless amount of knowledge achieved by humankind along with the powerful set of mechanisms to access it, and mostly our renewed priorities, personal values of ways of doing (fig. 8) guarantee a worthy and fertile service of research to architecture and, consequently, of architecture to the society and the planet.
