## 1. Introduction

Society is ageing fast. A number of studies [1, 2, 3, 4] confirm this trend and highlight a negative consequence of this trend: the increased lack of care and assistance for the elderly. Elderly care (paid and unpaid) requires a high cost for the families [3], monetarily, physically, and psychologically. This cost is hard to translate to a single value, and even harder to attain help from governmental sources or external help. Furthermore, family members who provide care to their elderly relatives often report high tension levels in their relationships, degrading the quality of life for all parties [3].

From an economics perspective there are two serious issues: the lack of money for formal or informal care and the decreasing availability of formal medical care. Families are now facing serious economical stress by having elderly people under their care [3]. Elderly people tend to have health issues that require expensive treatments. Aggravating this situation, some elderly people require constant assistance, but most families are unable to hire a nurse, with the result that a family member then needs to take up this task, possibly impacting on family income. Governments are unable to cover all aspects of assistance or subsidise elderly care. For instance, in the United Kingdom there is currently a serious shortage of available hospital beds, which in particular is affecting the elderly population [5]. As a result, hospitals ask people to stay at home if possible, and discharge people sooner.

---

22 This leaves a significant number of people at home, without proper care. The  
23 study by Ewbank et al. [5] also found that waiting times for admittance are  
24 increasing, reporting that only half of the demand is met. This issue also  
25 affects the elderly as they have to wait long periods of time before they can  
26 receive medical care.

27 The issue of delivering medical care has a great impact on the elderly  
28 community. The briefing of *Age UK* [3] reports that at the age of 80, six in  
29 seven elderly persons will have a long term health condition, and by age 85,  
30 80% will have at least two long term health conditions. Additionally, 1 in 3  
31 people aged 80 will have difficulties undertaking five or more tasks of daily  
32 living unaided, whilst when reaching 85 years old, the number increases to 2  
33 in 3.

34 Cognitive problems in particular are very difficult to handle for family  
35 members and caregivers. We are now observing an increase of the number  
36 of people that suffer from these health issues [6, 3]. Cognitive diseases are  
37 usually very debilitating and can make sufferers very frail. Not being able  
38 to perform routinely activities of daily living (ADL) can have a negative  
39 impact on the moral of the elderly, leading to cases of severe depression.  
40 Constant care is typically needed in these cases and, as pointed out earlier, it  
41 is difficult for families and governments to tackle these situations adequately.  
42 Without a caregiver, the elderly are exposed to increased risks in the house  
43 and these risks are higher when they suffer from cognitive problems. Episodes  
44 of confusion are common and the typical response is panic and attempting to  
45 leave the room they are in, thus leading to falls and serious bodily injuries.  
46 There is a pressing need for help in terms of care and assistance whilst offering  
47 independence and safety [7]. Technology can be used to provide assistance  
48 through recommender systems, assistant robots, smart homes, etc. [8, 9].

#### 49 *Improving Quality of Life*

50 Improving the quality of life of all citizens is critical, and is going to  
51 be a social priority in the next years. The European Union has recognized  
52 these issues and put in place funding for projects that address them [10].  
53 This has contributed to stimulate activity in this area and as a result there  
54 are currently a number projects, both in academia and industry, developing  
55 solutions to improve the quality of life for both the elderly and the caregivers.

56 In particular, in the Ambient Assisted Living (AAL) domain [11, 12] we  
57 can find several solutions that aim to improve people's quality of life through  
58 the use of technology. The focus of AAL research is primarily on developing

59 low-cost technological solutions for the elderly and disabled people, to help  
60 them with their daily tasks.

61 A key sub-area of AAL focuses on Cognitive Assistants (CA). This is a  
62 relatively new area that is now growing fast, gaining traction in both the  
63 academic and corporate environments. Thanks to advances in both hard-  
64 ware and Artificial Intelligence solutions, the CA area has come of age, as  
65 the technology is now mature enough to enable the deployment of effective  
66 solutions.

## 67 **2. Cognitive Assistants**

68 Research in CA focuses on the development of technological devices that  
69 assist people with cognitive tasks in their daily lives, helping them, for in-  
70 stance, to remember how to wash their hands, where is the soap and to turn  
71 off the water. Projects in the CA area come in many shapes and forms,  
72 some are pure software projects while others are a mixture of software and  
73 hardware.

74 After the age of 60 human beings start to decline in terms of memory  
75 and cognitive elasticity. This decline can often contribute to aggravate their  
76 current physical problems [13]. Furthermore, people with cognitive problems  
77 tend to be more stagnant and perform fewer activities, thus being exposed to  
78 a faster body condition decay. A way to prevent further decline of the cogni-  
79 tive abilities is to exercise memory through specific exercises. These usually  
80 focus on recollecting memories (past events, people, etc.), thus fortifying the  
81 neurons and creating new synapses [14]. There are also brain games that are  
82 specifically designed to prevent the decay of the cognitive capacity. While  
83 these games are effective, research has showed that is better to use one's  
84 personal information and memory [15].

85 Helping people to remember is therefore the main focus of CA research,  
86 which aims to help people with their daily activities by providing informa-  
87 tion about past events or people. For instance, CA projects may focus on  
88 intelligent calendars, activity recognition systems or memory banks. The  
89 domain of action of CA projects is broad and touches several aspects of hu-  
90 man activities. CA solutions can be deployed in the homes of the elderly,  
91 in schools, and even in hospital environments; they may use screens, mobile  
92 devices, televisions and robots as methods of interaction. The diversity and  
93 potential of CA solutions are illustrated below with a few examples.

94 [16, 17] propose an intelligent calendar that helps people remember their  
95 tasks, as well as suggesting social events in an effort to promote active ageing.  
96 [18] proposes a system that presents information about the current health  
97 condition of its users, exploiting sensor systems that monitor their vital signs.  
98 [19, 20] discuss the interaction between robots and elderly people, and suggest  
99 strategies to increase their acceptance. [21] proposes using daily tasks as  
100 games and gamification to engage the elderly, allowing them to have a healthy  
101 contest. Finally, [22] proposes a system that shows information based on the  
102 current location of the users, thus helping them to exercise their memory and  
103 geospatial abilities.

### 104 3. Conclusions

105 This special issue presents the most recent advances in the area of cog-  
106 nitive assistants. Thus, it is intended to provide an overview of the research  
107 being carried out in this interdisciplinary field.

108 These days CA technology is being extended to what is sometimes called  
109 “smart advisors”, which provide a universal human-centric computer infor-  
110 mation solution. Smart advisors combine generic decision support tech-  
111 niques with context-awareness and personalized recommendation using ma-  
112 chine learning. They aim to help people in their daily activities in a general  
113 sense. Today, a number of prototypes of such systems exist. Some of them  
114 are well integrated into online services, as well as mobile devices. Others  
115 are embedded into dedicated robot prototypes, often oriented on care tak-  
116 ing. Recently a more general concept of companion technologies has been  
117 introduced.

118 The articles contained in this special issue are very heterogeneous in terms  
119 of scope, region and are by people that are a reference in this field. Five  
120 articles compose this Special Issue, and they are distributed globally, with  
121 contributions from the following countries: Germany, New Zealand, Spain,  
122 Taiwan, and United States of America. This shows the interest of academia  
123 in the CA area and the level of development that is currently underway, and  
124 provide different perspectives related to their own culture. Next we present  
125 the accepted articles with a brief explanation of their themes and aims.

126 *MyMemory: A Mobile Memory Assistant for People with Trau-*  
127 *matic Brain Injury.* This article presents MyMemory, a cognitive assistant  
128 that aims to assist Traumatic Brain Injury patients in coping with their mem-  
129 ory impairments. It consists of a mobile application that displays reminders

130 to its users, providing extensive context about the activity to be performed.  
131 Furthermore, the article presents a study that reports a high level of accep-  
132 tance by the MyMemory users, including improvements in memory function  
133 and autobiographical memory.

134 ***Deciding the Different Robot Roles for Patient Cognitive Training.***

135 This article presents a system that interacts with caregivers and care-receivers  
136 via a robot. The aim is to learn the parameters of tests (Syndrom Kurztest)  
137 from the caregivers and perform those tests on the care-receivers. The goal  
138 is to have a complete interaction loop, improving the levels of engagement  
139 and increasing the tests' confidence levels. Thus, attaining reliable results  
140 about the cognitive impairments of the care-receivers.

141 ***Attention Allocation for Human Multi-Robot Control: Cognitive***  
142 ***Analysis based on Behavior Data and Hidden States.***

143 This article presents a strategy to improve the cognitive awareness of robot operators in  
144 difficult tasks, e.g., navigating a robot in a challenging environment. They  
145 have found that Hidden Markov Models demonstrate fundamental differences  
146 among the queuing mechanisms and reliability conditions. Thus, they can  
147 be helpful in investigating the use of human cognitive resources under mul-  
148 titasking environments.

149 ***A Cognitive Assistant for Improving Human Reasoning Skills.***

150 This article presents LIZA, a pedagogical agent that aims at improving the reason-  
151 ing and decision-making dialogue ties of its users using natural language. It  
152 is used on an e-Learning environment, thus it is a conversational tool (using  
153 chat) that displays information according to the type of conversation. The  
154 goal is to engage the users and to present data saving the users from reading  
155 irrelevant information, thus achieving higher learning gains in comparison to  
156 classical e-Learning platforms.

157 ***A Cognitive Assistant for Learning Java featuring Social Dialogue.***

158 This article presents an architecture that aims to improve the students' learn-  
159 ing rate through a social dialog. The aim is to identify the students doubts  
160 and provide exact information that will help them advance in their studies.  
161 The goal is to keep the students engaged and improve their satisfaction levels  
162 and learning curve. This article also presents an evaluation that validates  
163 the hypothesis.

164 These five articles show distinct scopes and aims within the CA domain.  
165 We believe that it shows maturity and reveals that the society is in great  
166 need of technological solutions that improve their lives through what could  
167 be considered little gestures (helping in ADL) that have a great impact on  
168 wellbeing.

169 Finally, we would like to thank the reviewers who helped increase the  
170 excellency of this special issue.
