Summary (250 words, w. references)

Plant survival depends on the optimal use of resources under variable environmental conditions. Among the mechanisms that mediate the balance between growth, differentiation, and stress responses, the regulation of transcriptional activity by DELLA proteins stands out. In angiosperms, DELLA accumulation promotes defense against biotic and abiotic stress and represses cell division and expansion, while the loss of DELLA function is associated with increased plant size and sensitivity towards stress¹. Given that DELLA protein stability is dependent on gibberellin (GA) levels², and GA metabolism is influenced by the environment³, this pathway is proposed to relay environmental information to the transcriptional programs that regulate growth and stress responses in angiosperms^{4,5}. However, *DELLA* genes are also found in bryophytes, whereas canonical GA receptors have been identified only in vascular plants^{6–10}. Thus, it is not clear whether these regulatory functions of DELLA predated or emerged with typical GA signaling. Here we show that, as in vascular plants, the only DELLA in the liverwort *Marchantia polymorpha* also participates in the regulation of growth and key developmental processes, and promotes oxidative stress tolerance. Moreover, part of these effects is likely caused by the conserved physical interaction with the MpPIF transcription factor. Therefore, we suggest that the role in the coordination of growth and stress responses was already encoded in the DELLA protein of the common ancestor of land plants, and the importance of this function is underscored by its conservation over the past 450 M years.

Gibberellin, *Marchantia polymorpha*, plant growth, oxidative stress, plant hormone, plant evolution

Results and Discussion

MpDELLA accumulation affects cell division

The genome of *M. polymorpha* encodes a single MpDELLA gene (Mp5g20660)^{7,11}. Attempts to generate Mp*della* loss-of-function mutants with several sgRNAs yielded only mutations that did not significantly alter the protein sequence (*i.e.*, the locus was editable, but hypomorphic alleles were not

recovered) (Figure S1A). Whether this is due to lethality or impaired recovery of mutant transgenic plants is presently unknown. Lethality caused by loss of DELLA function has not been previously reported; however, DELLA hypomorphic mutants show defects in gamete formation¹². Given that the life cycle of *M. polymorpha* is dominated by the haploid phase, we cannot rule out that MpDELLA is also essential for gametophyte survival. Thus, to investigate its biological function, we generated transgenic plants overexpressing MpDELLA either under the control of the CaMV 35S promoter, or the *M. polymorpha* *ELONGATION FACTOR1 α* (MpEF1 α) promoter. In all cases, MpDELLA constitutive overexpression lines displayed smaller thallus sizes than the wild type, which was already evident in two-week-old plants (Figures 1A, 1C, and S1B). To test MpDELLA function within its native expression range, plants were also transformed with additional copies of the gene including its own promoter, coding sequence and a translationally fused β -glucuronidase reporter (*gMpDELLA-GUS*). These lines were moderately high in MpDELLA expression (Figure S1B) but also showed significantly smaller thallus (Figures 1A and 1C). Introducing additional copies, native-promoter driven translational fusion with the β -glucuronidase (GUS) reporter (*gMpDELLA-GUS*) had a moderate, but similar effect (Figures 1A, 1C, and S1B). As members of the GRAS family of transcriptional regulators, DELLA proteins have been shown to function in the nuclei of angiosperms^{13,14}. Nuclear localization was also observed for MpDELLA-Cit fusion proteins (Figure S1D). Following such observation, we constructed the inducible MpDELLA-GR lines, which constitutively expressed MpDELLA fused with the rat glucocorticoid receptor. Dexamethasone (DEX)-induced growth impairment was observed in a dose-dependent manner (Figure S1E and S1F). These results support the hypothesis that DELLA accumulation inhibits vegetative growth in *M. polymorpha* and is similar to size alterations observed in several flowering plant species¹⁵⁻¹⁸.

In *Arabidopsis*, one of the mechanisms proposed for controlling plant size is the DELLA-dependent reduction of cell proliferation rate¹⁹⁻²¹. To investigate if cell division is affected in MpDELLA overexpression lines, we labelled S-phase cells with 5-ethynyl-2'-deoxyuridine (EdU) and observed the nuclear signals around the apical region. All overexpression lines showed significant reduction in the total number of EdU-positive nuclei, which were distributed in a smaller area

compared with wild-type plants (Figures 1B, 1D-E, and S1G-I). For further confirmation of the cell-cycle regulation by MpDELLA, we introduced a G2-M phase reporter (*proMpCYCB;1:Dbox-GUS*) into the MpDELLA-GR background. After a two-day treatment with 1 μ M DEX, the spatial range of GUS signals was notably restricted compared to the mock group (Figure 1F), suggesting a reduction in active cell division.

Histochemical analysis of transcriptional and translational GUS reporters showed that MpDELLA is broadly expressed in the thallus, but the natively expressed MpDELLA protein preferentially accumulated in the apical notch region, where cell division actively occurs (Figures 1G and S1J). This result is comparable with the observations in Arabidopsis showing that DELLA proteins are expressed in the shoot and root apical meristems^{20,22,23}. Therefore, MpDELLA may also restrict growth by inhibiting cell proliferation in the meristematic regions of *M. polymorpha*.

Cyclin-dependent kinase inhibitors (CKIs) have been shown to participate in the DELLA-mediated decrease of cell proliferation in Arabidopsis^{19,20}. The *M. polymorpha* genome contains two CKI genes, MpSMR (Mp1g14080) and MpKRP (Mp3g00300), which belong to the plant-specific SIAMESE (SIM) protein family and the conserved Kip-related proteins (KRP), respectively¹¹. To test genetically if MpDELLA acts through MpSMR to control thallus size, we introduced MpSMR loss-of-function mutations into a MpDELLA-GR line using the CRISPR/Cas9 system²⁴ (Figure S1K) and examined growth in the absence and the presence of DEX. Gemmalings carrying the *Mpsmr^{ge}* alleles were moderately larger than the wild type in mock conditions. More importantly, the growth inhibition caused by activation of MpDELLA-GR was attenuated in the *Mpsmr^{ge}* mutants (Figure 1G), supporting the functional relevance of cell division in MpDELLA-mediated growth restriction. *Mpsmr^{ge}* alleles did not fully abolish the response to DEX induction, indicating that MpDELLA might also suppress cell proliferation through additional pathways.

Taken together, these results suggest that the regulation of plant size through the interference with cell division is a shared DELLA function in land plants.

MpDELLA regulates development through physical interaction with MpPIF

Distribution of the *gMpDELLA-GUS* signal was also detectable inside gemmae cups, preferentially in developing gemmae (Figures 1H and S1J). Interestingly, both constitutive and induced *MpDELLA* overexpression exhibited a loss of gemma dormancy, revealed by early gemma germination inside the gemma cups (Figures 2A and 2B). This effect on gemma dormancy resembles the capacity to germinate in the dark of *Mppif^{ko}*, which is a loss-of-function mutant of *MpPHYTOCHROME INTERACTING FACTOR* (*MpPIF*, Mp3g17350)²⁵. Indeed, we observed a similar loss of dormancy in gemma cups of *Mppif^{ko}* lines (Figures 2C and S2A). Reciprocally, DEX induction was found to promote gemma germination in darkness in the *MpDELLA-GR* lines (Figure S2B). In addition, *MpDELLA* overexpression lines, including *gMpDELLA-GUS*, displayed a significant delay in the induction of sexual reproduction (Figure 2D), which has also been observed in *Mppif^{ko}*²⁶. These similarities indicate a possible functional connection between *MpDELLA* and *MpPIF*, which has been previously reported in *Arabidopsis* for the regulation of apical hook formation and other developmental processes^{27–29}.

In *Arabidopsis*, DELLA proteins interact physically with the PIF transcription factors and prevent their binding to downstream targets^{28,29}. It is likely that this mechanism is also conserved in *M. polymorpha*, since we observed that *MpDELLA* interacts physically with *MpPIF* in a yeast two-hybrid assay and *in vivo* by co-immunoprecipitation and Bimolecular Fluorescence Complementation assays (Figures 2E, 2F and S2C). Further *MpPIF* deletion analyses suggested that the GRAS domain of the *MpDELLA* protein specifically interacts with the bHLH domain of *MpPIF* (Figures S2D and S2E), paralleling results seen in *Arabidopsis*²⁸. The inhibitory effect of the interaction was verified by dual-luciferase transactivation assays in tobacco. In a dose-dependent manner, *MpDELLA* inhibited the *MpPIF*-activation of the *AtPIL1* promoter (Figure 2G), a known direct target for PIFs in *Arabidopsis*³⁰.

To assess the biological relevance of the interaction between *MpDELLA* and *MpPIF*, we tested if an increase in the dosage of *MpPIF* would suppress the phenotypical defects caused by high *MpDELLA* levels. Indeed, the reduction of gemma dormancy in gemma cups caused by *MpDELLA* induction was notably attenuated in *pro35S:Cit-MpPIF MpDELLA-GR* plants (Figures 2H and S1B-C). Similarly, gemma germination in darkness and the delay in gametangiophore

formation of MpDELLA-GR plants were significantly suppressed in the presence of higher MpPIF levels, both in the absence and presence of DEX treatments (Figures 2I and S2F). No rescue of plant growth by elevated MpPIF levels was observed in the double overexpression lines (Figure S2G). Given the normal vegetative growth of *Mppif^{ko}*²⁵, the cell-cycle-repressing function of MpDELLA does not appear to be mediated by MpPIF.

These results suggest that DELLA/PIF-mediated modulation of developmental programs could be a conserved mechanism that was already present in the common ancestor of land plants.

MpDELLA promotes flavonoid accumulation and oxidative stress tolerance

To investigate the downstream targets of the MpDELLA-MpPIF module, we analyzed the transcriptomic changes in *pro35S:MpDELLA-Cit* lines and the *Mppif^{ko}* mutant. As MpPIF proteins are stabilized by far-red light²⁵, *Mppif^{ko}* plants were evaluated at 0, 1, or 4 hours after far-red light irradiation (see STAR Methods). MpDELLA overexpression caused the upregulation of 1483 genes and the downregulation of 560 genes (Figure 3A and Data S1). The analysis of differential gene expression in the *Mppif^{ko}* mutant yielded a total of 339 and 333 genes, up- and down-regulated at least at one time point, respectively (Data S1). As expected, the most abundant set of MpPIF-regulated genes was obtained after the 4-hour far-red treatment (Figure S3A), so we used this set for further analyses. More than half of the upregulated genes in *Mppif^{ko}* were also upregulated in *pro35S:MpDELLA*, and there was a statistically significant overlap also among genes downregulated in both genotypes (Figure 3A), indicating a strong correlation between MpDELLA overexpression and loss of MpPIF functions. As a confirmation, three differentially expressed genes were tested by qPCR, and they all showed expression changes consistent with the RNA-seq (Figure S3B).

Gene ontology enrichment analysis highlighted the regulation of stress response and secondary metabolism processes in both *pro35S:MpDELLA-Cit* and *Mppif^{ko}* upregulated datasets, especially with the enrichment of terms involving phenylpropanoid and flavonoid biosynthesis (Figure 3B and Data S1). In particular, many genes encoding PHENYLALANINE AMMONIA LYASE (PAL),

CINNAMATE 4-HYDROXYLASE (C4H) or CHALCONE SYNTHASE (CHS) were indeed upregulated, as also confirmed by qPCR (Figures 3C and 3D). In the case of *Mppif^{ko}*, the observed net upregulation of flavonoid biosynthesis genes was mainly due to far-red-induced downregulation in the wild type (Figure S3C), suggesting a suppressive role for MpPIF.

Staining with diphenylboric acid 2-aminoethyl ester confirmed the increased accumulation of flavonoid compounds caused by MpDELLA overexpression or MpPIF loss-of-function (Figures 4A and S4A). Furthermore, the MpDELLA-induced increase of flavonoid signals was less evident when MpPIF is also overexpressed in MpDELLA-GR (Figure S4B). Quantitative analysis of flavonoids showed increases in luteolin 7'-O-glucuronide, and 4',7-dihydroxyflavan-3-ol content in MpDELLA overexpression lines and *Mppif^{ko}* plants (Figure S4C and Table S1). Similar to other plants, increased flavonoid biosynthesis is a protective response against UV-B-induced oxidative stress in *M. polymorpha*³¹. The ability to enhance the production of these antioxidant compounds suggests a general function for MpDELLA in this stress response, which might be fulfilled in coordination with its inhibition of MpPIF.

To test if MpDELLA levels influence the response to oxidative stress, we examined the tolerance of plants overexpressing MpDELLA to methyl viologen (MV), an inducer of oxidative stress³². Six-day-old gemmalings were transferred to plates containing 100 μ M MV for 10 days, after which they were allowed to recover for at least one week. All MpDELLA overexpressing plants, including those with the native MpDELLA promoter, showed a significantly higher survival rates compared to wild-type plants (Figure 4B). These results suggest that the increased production of flavonoids caused by higher MpDELLA levels could be responsible for the protection against oxidative stress. This hypothesis is further supported by the observation that *Mppif^{ko}* mutants also displayed enhanced resistance to MV (Figure 4B), and that the MpDELLA-dependent tolerance was attenuated by MpPIF overexpression (Figure S4D).

In Arabidopsis, the role of DELLAs in the coordination between growth and stress responses is visualized by GA reduction and accumulation of DELLA in response to certain types of stress, coupled to increased tolerance and a variable degree of growth impairment³³. Although *M. polymorpha* does not possess a GID1-like GA receptor that might modulate MpDELLA protein stability, we found

that exposure of 10-day-old gemmalings to MV provoked an increase in MpDELLA gene expression (Figure 4C and 4D). Such MpDELLA accumulation was concomitant with marked growth arrest and reduced cell division (Figures 4E and S4E). Interestingly, *Mppi^{fko}* mutants were as large as wild-type plants both in the absence and in the presence of MV (Figure 4E), confirming that the control of *M. polymorpha* thallus size is largely independent of MpPIF.

In summary, we have shown that MpDELLA can modulate cell division, developmental responses and tolerance to oxidative stress in *M. polymorpha* through molecular mechanisms that are shared with angiosperms (Figure 4F). That our results reflect the function of the endogenous MpDELLA protein is supported by the following observations: (i) mild overexpression from the native promoter caused similar phenotypic effects as constitutive and ectopic overexpression; (ii) local induction of MpDELLA-GR in apical notches (where endogenous MpDELLA accumulates) caused growth impairment (Figure S4F-H); and (iii) the effect of MpDELLA accumulation on growth is dose-dependent. The involvement of MpDELLA in growth control is in contrast with the previous proposal that this function emerged with vascular plants, based on the phenotype of *P. patens della* mutants⁹. However, this might reflect a specific functional loss in mosses, given that PpDELLAa still retains the capacity to impair growth in particular contexts, as through heterologous expression in Arabidopsis⁹. Thus, the functional conservation between angiosperm and bryophyte DELLAs implies that the role in the optimization of growth and the responses to disadvantageous environments was already encoded in the ancestral land plant DELLA protein, and the canonical GA signaling might have simply hijacked these functions when the pathway emerged in vascular plants.

Figure 4. Involvement of MpDELLA in the response to oxidative stress.

(A) Images of 14-day-old gemmalings, stained with diphenylboric acid 2-aminoethyl ester to show general flavonoid content. Scale bar, 5 mm.

(B) Percentage of surviving apical notches after a 10-day treatment with 100 μ M MV in different transgenic lines. Dots represent independent experiments (n=3).

(C) Relative expression level of MpDELLA determined by RT-qPCR in 14-day-old gemmalings grown in mock or 10 μ M MV-supplemented media. Error bars represent standard error; n=3.

(D) GUS-stained MpDELLA reporter lines, showing the increased signals in the apical notches of 13-day-old plants after a 6-day treatment with mock or 10 μ M MV.

(E) Size of 14-day-old gemmalings grown on mock or 0.5 μ M MV-supplemented medium. n=19 (WT Mock), 16 (WT MV), 36 (Mppif^{ko} Mock), 28 (Mppif^{ko} MV), 25 (gMpPIF/Mppif^{ko} Mock), 24 (gMpPIF/Mppif^{ko} MV).

(F) Model for the regulation of growth, development and stress responses by MpDELLA. Under stress, MpDELLA would accumulate in apical notches protecting them through the MpPIF-dependent production of antioxidant compounds, and suppressing growth by inhibiting cell divisions. The interaction with MpPIF also causes alterations in developmental processes, such as gemma dormancy or gametangiophore formation.

All plants were grown under long-day conditions. In B, E, dots represent biological replicates, and the horizontal lines represent mean values. Statistical groups were determined by Tukey's Post-Hoc test (p<0.05) following ANOVA analysis.

RESOURCE AVAILABILITY

Lead Contact

Further information and requests for resources and reagents should be directed to and will be fulfilled by the Lead Contact, Miguel A. Blázquez (mblazquez@ibmcp.upv.es).

Materials availability

Plasmids and plant materials generated in this research are all available from the Lead Contact upon request. Please note that the distribution of transgenic plants will be governed by material transfer agreements (MTAs) and will be dependent on appropriate import permits acquired by the receiver.

Data and Code Availability

Raw RNA sequencing datasets generated during this study were deposited to the Short Read Archive at the National Center for Biotechnology Information (NCBI) or the Sequence Read Archive at DNA Data Bank of Japan (DDBJ) under Bioprojects PRJNA695248 and PRJDB11176. The modified ITCN plugin for ImageJ is available at <https://github.com/PMB-KU/CountNuclei>. R scripts used for processing EdU data, Blast2GO annotation and RNA-seq analysis were deposited to <https://github.com/dorrenasun/MpDELLA>.

EXPERIMENTAL MODEL AND SUBJECT DETAILS

Plant Materials and Growth Conditions

Marchantia polymorpha accession Takaragaike-1 (Tak-1; male)³⁴ was used in this study as the wild-type (WT). Female lines *Mppi*^{ko} and *gMpPIF/Mppi*^{ko} were previously described as *pif*^{ko} #1 and *proPIF:PIF/pif*^{ko} #1, respectively²⁵. *M. polymorpha* plants were cultured on half-strength Gamborg's B5³⁵ medium with 1% agar at 21-22°C. Light conditions are specified in each figure; generally, long day (LD) conditions refer to cycles with 16 hours of light (90-100 $\mu\text{mol m}^{-2} \text{s}^{-1}$) and 8 hours of darkness in a Percival growth chamber (E-30B), while continuous white light (cW) was supplemented at the intensity of 50-60 $\mu\text{mol m}^{-2} \text{s}^{-1}$ by cold

cathode fluorescent lamp (CCFL; OPT-40C-N-L, Optrom, Japan) in a growth room.

Nicotiana benthamiana wild-type seeds were sown in pots filled with regular soil mixture from a local provider and covered for a week with a plastic humidity dome after watering. Plants grown in a growth room under long day conditions (16 of light [$120 \mu\text{mol m}^{-2} \text{s}^{-1}$] and 8 hours of darkness) at 24°C (light) and 20°C (darkness).

METHOD DETAILS

Cloning and plasmid construction for plant transformation

Various Gateway-compatible entry vectors related to MpDELLA were generated. The full length CDS, GRAS domain (amino acids 173 to 560), promoter (4.3kb upstream of ATG), and genomic (promoter and CDS) regions were amplified from genomic DNA by PCR using Phusion High-Fidelity Polymerase (Thermo Fisher Scientific) with attB-containing primers, and introduced into pDONR221 (Thermo Fisher Scientific) vector using Gateway BP Clonase II Enzyme mix (Thermo Fisher Scientific) to generate pENTR221-MpDELLA, -MpDELLA^{GRAS}, -_{pro}MpDELLA and -gMpDELLA, respectively. The CDS region was also amplified with KOD FX Neo DNA polymerase (Toyobo Life Science) and directionally cloned into pENTR/D-TOPO (Thermo Fisher Scientific) to create pENTR-MpDELLA. For pENTR1A-_{pro}MpDELLA-short, a slightly shorter promoter region was amplified with PrimeSTAR GXL DNA Polymerase (TaKaRa Bio) and inserted between the *Sall* and *NotI* sites of pENTR1A (Thermo Fisher Scientific) with T4 DNA ligase (TaKaRa Bio). pENTR1A-gMpDELLA-short was further created by seamless integration of the CDS fragment with the In-Fusion Cloning kit (TaKaRa Bio). Finally, both constructs were extended at the 5' end by In-Fusion insertion to create pENTR1A-_{pro}MpDELLA and pENTR1A-gMpDELLA, matching with the lengths of pENTR221 counterparts.

To create the vectors for MpDELLA overexpression, pENTR221-MpDELLA and pENTR211-gMpDELLA were recombined with pMpGWB106 and pMpGWB107³⁶ using Gateway LR Clonase II Enzyme mix (Thermo Fisher Scientific) to generate pMpGWB106-MpDELLA and pMpGWB107-gMpDELLA,

respectively. pENTR-MpDELLA was recombined with pMpGWB310 and pMpGWB313 for the generation of pMpGWB310-MpDELLA and pMpGWB313-MpDELLA, while pENTR1A_{-pro}MpDELLA and pENTR1A-gMpDELLA were recombined with pMpGWB304 to generate pMpGWB304_{-pro}MpDELLA and pMpGWB304-gMpDELLA. All these binary vectors were introduced into Tak-1 plants.

To monitor the cell division activity, the promoter (3.8 kb upstream of ATG) and coding sequence of the first 116 amino acids (including the destruction box) of MpCYCB;1 (Mp5g10030) was amplified with KOD -Plus- Ver.2 (Toyobo Life Science) and ligated into the the *Sall* and *EcoRV* sites of pENTR1A (Thermo Fisher Scientific) with Ligation high Ver.2 (Toyobo Life Science). The resulting plasmid was recombined with pMpGWB104 and then transformed into the *M. polymorpha* transgenic line MpDELLA-GR #5.

CRISPR/Cas9-based genome editing of MpDELLA and MpSMR (Mp1g14080) was performed as previously described³⁷. For MpDELLA, various guide RNAs were designed in the coding sequence and the 5'-untranslated region. For MpSMR, the guide RNA was designed upstream of the CDKI domain with Benchling³⁸. Double stranded DNA corresponding to the guide RNA protospacers were generated by annealing complementary oligonucleotides and inserted into Bsal-digested pMpGE_En03³⁷ by ligation using DNA T4 ligase (Promega), and then transferred to the binary vector pMpGE010³⁷ using Gateway LR Clonase II Enzyme mix (Thermo Fisher Scientific). *M. polymorpha* transformation was carried out in Tak-1 for MpDELLA, or the transgenic line MpDELLA-GR #5 for MpSMR, as described below.

For the construction of MpPIF-MpDELLA double overexpression lines, the MpPIF (Mp3g17350) coding region containing the stop codon was amplified from cDNA, cloned into pENTR/D-TOPO (Thermo Fisher Scientific), then recombined with pMpGWB105 using Gateway LR Clonase II Enzyme mix (Thermo Fisher Scientific). The resulting construct was transformed into the *M. polymorpha* transgenic line MpDELLA-GR #5.

All entry plasmids were confirmed by restriction enzyme digestion and Sanger sequencing. Destination vectors were confirmed by restriction enzyme digestion.

***Marchantia polymorpha* genetic transformation**

All the *M. polymorpha* transgenic lines are listed in the Key Resources Table. Transformants were obtained by agrobacterium-mediated transformation from regenerating thalli, using *Agrobacterium tumefaciens* strains GV3101 (pMP90 C58) or GV2260³⁹⁻⁴¹. Briefly, gemmae were grown in standard conditions (either cW or LD), during 14 days and cut into four pieces without apical notches, then cultured for 3 days on standard medium with 1% sucrose to induce regeneration. Regenerating fragments were co-cultured with *A. tumefaciens* in liquid medium with 100 mM acetosyringone with agitation. After three days the plants were washed six times with autoclaved water, incubated for 30 min in 1 mg/mL cefotaxime and plated on selective plates containing 0.5 μ M chlorsulfuron or 10 mg/l hygromycin (see Key Resources Table) and 100 mg/l cefaxime.

Regenerating transgenic plants (T1) checked by PCR amplification from crude DNA extracts. Gemmae derived from T1 plants (G1) were confirmed and further descendants used for experiments. For CRISPR/Cas9-based genome editing, G1 plants were checked by PCR amplification followed by Sanger sequencing, to assess genome editing events, and confirmed for stable editing in G2 plants derived from gemmae of G1 plants.

Plant growth and EdU staining

For the measurement of plant sizes, images of the whole culturing plates were taken vertically above with a digital camera (Canon EOS Kiss X7i). The thallus projection areas were analyzed with ImageJ 1.52a⁴² by thresholding the images with the default algorithm on the blue color channel and batch-measured with the function “Analyze Particles”.

For the detection of S-phase cells, constitutive- and native-promoter MpDELLA overexpression lines were grown from gemmae for seven days under cW. MpDELLA-GR lines were grown from gemmae under cW for five days, then transferred onto the plates containing mock solvent or 1 μ M dexamethasone

(DEX) and cultured for two days. All the plants were labeled with 20 μ M 5-ethynyl-2'-deoxyuridine (EdU) in liquid half-strength Gamborg's B5 medium under cW for 2 h. Then they were fixed with 3.7% formaldehyde for 1 h, washed for 5 min twice with phosphate buffer saline (PBS), and permeabilized in 0.5% Triton X-100 in PBS for 20 min. After two 5-min washes with 3% bovine serum albumin (BSA) in PBS, samples were incubated with the reaction mixture from Click-iT EdU Imaging Kit with Alexa Fluor 488 (Invitrogen) in the dark for 1 h. After staining, samples were protected from light, washed twice with 3% BSA in PBS and soaked in ClearSee solution⁴³ for 3-7 days. After that, the samples were mounted to slides with 50% glycerol and observed with Keyence BZ-X700 all-in-one fluorescence microscope. Z-stacks of fluorescence images were taken in 2- μ m steps with the YFP filter (Keyence 49003-UF1-BLA, excitation at 490-510 nm, detection range 520-550 nm) and merged together with the BZ-X Analyzer software (1.3.1.1).

Microscopy & histochemical analysis

For GUS activity assay, plants were vacuum-infiltrated with GUS staining solution (50 mM sodium phosphate buffer pH 7.2, 0.5 mM potassium-ferrocyanide, 0.5 mM potassium-ferricyanide, 10 mM EDTA, 0.01% Triton X-100 and 1 mM 5-bromo-4-chloro-3-indolyl- β -D-glucuronic acid) for 15 min, and then incubated at 37 °C overnight (>16 hours). Samples were de-stained with 70% ethanol and imaged under an Olympus SZX16 stereoscope. To prepare agar sections, stained samples were embedded in 6% agar and sectioned into 100- μ m slices with LinearSlicer PRO 7 (DOSAKA EM, Kyoto, Japan), then imaged with Keyence BZ-X700 microscope in the bright-field.

Confocal laser scanning microscopy on *gMpDELLA-Cit* gemma was performed using a Leica TCS SP8 equipped with HyD detectors. A white light laser was used to visualize Citrine (excitation 509 nm). Diphenylborinic acid 2-aminoethyl ester (DPBA) staining was used to visualize flavonoids as previously described⁴⁴. Whole thalli were stained for 15 minutes at 0.25% (w/v) DPBA and 0.1% (v/v) Triton X-100. Epifluorescence microscopy of stained flavonoids in

gemmalings was performed on a Leica DMS1000 dissecting microscope using a GFP filter for detection of DPBA fluorescence.

Scoring of gemma cup dormancy

To score the dormancy of gemma cups, constitutive- and native-promoter MpDELLA overexpression lines, as well as *Mppif^{ko}* plants were grown from gemmae on half-strength Gamborg's B5 plates with 1% sucrose under cW for 28 days. MpDELLA-GR and *pro35S:Cit-MpPIF* MpDELLA-GR lines were grown on half-strength Gamborg's B5 plates without sucrose under cW for 10 days, then transferred onto plates containing mock solvent or 1 μ M DEX and cultured for another 20 days before evaluation. Gemma cups with observable gemmae were observed carefully under stereoscopes, marked on photos taken with a digital camera and then counted. If a gemma with rhizoid and/or growth expansion was observed in a certain gemma cup, it is considered as non-dormant. Representative plants were also photographed with Leica M205C stereo microscopes to show the dormancy of gemma cups in different transgenic lines.

Gemma germination assay

Gemma germination assays were carried out following the previous publication²⁵. In each experiment, fifty gemmae of each group were planted onto half-strength Gamborg's B5 plates containing 1% sucrose under green light, then treated with far-red light (30 μ mol photons $m^{-2} s^{-1}$) for 15 minutes. For MpDELLA-GR related experiments, 1 μ M DEX or the mock solvent was supplemented in the agar plates. After one day of imbibition in the dark, gemmae were irradiated with nothing or a pulse of red light (4500 μ mol photons m^{-2}) and then cultured for another six days in the dark. Photos of each gemmae were taken using Leica M205C or Olympus SZX16, then evaluated for germination based on growth expansion and/or the development of rhizoids.

Gametangiophore formation observation

To monitor the progress of gametangiophore formation in transgenic lines shown in Figure 2B, plants were grown from gemmae on half-strength Gamborg's B5 plates with 1% sucrose under continuous white light ($\sim 50 \mu\text{mol photons m}^{-2} \text{s}^{-1}$, in a CCFL growth cabinet from Nippon Medical & Chemical Instruments, LH-80CCFL-6CT) supplemented with far-red light ($\sim 20 \mu\text{mol photons m}^{-2} \text{s}^{-1}$ provided by diodes from Valore, Japan: VBL-TFL600-IR730. Referred to as cW+FR.). Individual plants were examined and counted for visible gametangiophores each day under stereoscopes. For the experiment in Figure 2I, gemmae of inducible lines or the wild-type control were grown on half-strength Gamborg's B5 plates with 1% sucrose with no DEX under cW for 10 days, then half pieces of thallus were transferred onto plates containing 1 nM DEX or mock solvent and cultured under cW+FR. Gametangiophore formation progresses were observed for half plants similarly as described above.

Yeast-two hybrid assays

For yeast two-hybrid analyses, MpPIF full length CDS and CDS fragments were amplified from cDNA and introduced into pCR8 using the pCR8/GW/TOPO TA Cloning Kit (Thermo Fisher Scientific) to generate pCR8-MpPIF and -MpPIFdel1-4. Then they were recombined with pGADT7-GW⁴⁵ using Gateway LR Clonase II Enzyme mix (Thermo Fisher Scientific) to produce Gal4-activation domain (AD) fusion proteins. To avoid the previously shown N-terminal transactivation of MpDELLA⁷, only the GRAS domain (pENTR221-MpDELLA^{GRAS}) was introduced into pGBKT7-GW⁴⁵ to fuse with the GAL4 DNA-binding domain. Yeast transformation was performed by lithium acetate/single-stranded carrier DNA/polyethylene glycol method as previously described⁴⁶. Y187 and Y2HGold yeast strains were transformed with pGADT7 and pGBKT7-derived expression vectors and selected with Synthetic Defined (SD) medium lacking leucine (-Leu) or tryptophan (-Trp), respectively. Subsequently, haploid yeasts were mated to obtain diploid cells by selection in SD/-Leu-Trp medium. Protein interactions were assayed by the nutritional requirement on histidine (His). SD/-Leu-Trp plates were used as growth control, and SD/-Leu-Trp-His plates supplemented with 5 mM 3-amino-1,2,4-triazole (3-AT, Sigma-Aldrich) was used for interaction evaluation. Spotting assays were performed using cultures with optical density =

1 ($OD_{600\text{ nm}} = 1$) as initial concentration in sequential drop dilutions, and plated with a pin multi-blot replicator. Photos of the same-fold dilutions were taken 3 days after plating.

Co-immunoprecipitation (Co-IP) and Bimolecular Fluorescence Complementation (BiFC) assays

Co-IP vectors were obtained by introducing MpDELLA CDS (pENTR221-MpDELLA) into pEarleyGate104 and MpPIF fragments (pCR8-MpPIF and -MpPIFdel3) into pEarleyGate201⁴⁷. For BiFC, pENTR211-MpDELLA and pCR8-MpPIF were recombined with pMDC43-YFN and pMDC43-YFC⁴⁸, respectively. *Agrobacterium tumefaciens* GV3101 containing binary plasmids for Co-IP and BiFC were used to infiltrate 4-week-old *Nicotiana benthamiana*. Briefly, overnight grown exponential cultures of *A. tumefaciens* were collected by centrifugation, resuspended in agroinfiltration solution (10 mM MES, 20 mM MgCl₂, 200 μM acetosyringone, pH 5.6), and incubated at room temperature during 4-6 hours. Resuspended cultures were adjusted to $OD_{600\text{ nm}} = 0.1$ with agroinfiltration solution and mixed in equal volumes when necessary. Agroinfiltration was carried out through abaxial leaf surfaces using 1 ml needle-free syringes.

For Co-IP, leaves were re-infiltrated with a solution of 25 μM MG-132 8 hours before collection 3 days after *A. tumefaciens* infiltration, grinded in liquid nitrogen and homogenized in 1 ml extraction buffer (50 mM Tris-HCl pH 7.5, 150 mM NaCl, 0.1% Triton, 2 mM PMSF, and 1x protease inhibitor cocktail [Roche]). Proteins were quantified using the Bradford assay. 50 μg of total proteins were stored as input. One milligram of total proteins was incubated for 2 h at 4°C with anti-GFP-coated paramagnetic beads and loaded onto μColumns (Miltenyi). Wash and elution from beads was performed according to manufacturer's instructions. Samples were analyzed by Western-blot after running two 12% SDS-PAGE gels in parallel. One gel was loaded with 25 μg of input, and 10% of eluted proteins; following wet transfer, the PVDF membrane was incubated with an anti-GFP antibody (JL8, 1:5000). The second gel was loaded with 25 μg of input, and 90% of eluted proteins and, after transfer, the membrane incubated with an anti-HA-HRP antibody (3F10, 1:5000). Chemiluminiscence was detected

with SuperSignal West Femto substrates (Thermo-Fisher Scientific) and imaged with a LAS-3000 imager (Fujifilm).

For BiFC, leaves were analyzed with a Zeiss LSM 780 confocal microscope 3 days after infiltration. Reconstituted YFP signal was detected with emission filters set to 503-517 nm. Nuclei presence in abaxial epidermal cells was verified by transmitted light.

Dual luciferase transactivation assay

MpDELLA and MpPIF-expressing vectors used for Co-IP (pEarleyGate104-MpDELLA and pEarleyGate201-MpPIF) were used as effector plasmids. A previously available construct with the *Arabidopsis thaliana* *PIL1* promoter controlling the firefly luciferase gene expression, and a constitutively expressed *Renilla* luciferase gene was used as reporter plasmid³⁰. The promoter consists of 1.8 kb upstream of the gene ATG codon, including three consecutive G-boxes known to be bound *in vivo* by PIF3. Transient expression in *N. benthamiana* leaves was carried by agroinfiltration as previously reported⁴⁹. The amount of infiltrated bacteria was set by OD_{600 nm} measurement of *A. tumefaciens* liquid cultures. Combinations of pre-set reporter-carrying bacteria (OD_{600 nm} = 0.1) and varying amounts of effector-carrying bacteria were mixed and co-infiltrated together. All the mixes were co-infiltrated alongside *p19* vector-carrying bacteria at a OD_{600 nm} = 0.01. Firefly (*Photinus pyralis*) and control *Renilla* luciferase activities were assayed in extracts from 1-cm in diameter leaf discs, using the Dual-Glo Luciferase Assay System (Promega) and quantified in a GloMax 96 Microplate Luminometer (Promega). Three leaf disc extracts were quantified per sample in each experiment and repeated for three times. Final quantifications represent means of ratios between firefly luciferase and *Renilla* luciferase read-outs in three independent experiments.

RNA isolation, cDNA synthesis, and RT-qPCR analysis

To examine the expression levels of MpDELLA and MpPIF in different transgenic lines, 14-day-old plants grown under cW were homogenized in liquid nitrogen. Total RNA was isolated with TRIzol reagent (Thermo Fisher Scientific) following

the manufacturer's instructions. After checking the concentration and quality of RNA using a NanoDrop 2000 spectrophotometer (Thermo Scientific), up to 3 μ g of total RNA was digested with RQ1 RNase-Free DNase (Promega) and reverse-transcribed using ReverTra Ace (Toyobo Life Science) and an oligo (dT)₂₀ primer. Resulting cDNA was diluted 10 times in ddH₂O, and 5 μ L was used for each 25- μ L quantitative real-time PCR (qPCR) with TaKaRa Ex Taq (TaKaRa Bio) and SYBR Green I Nucleic Acid Gel Stain (Lonza). Reactions were performed in a CFX96 real-time PCR detection system (Bio-Rad), with an initial denaturation step of 30 s at 95 °C and then cycled for 40 times with 5 s at 95 °C and 30 s at 60 °C. At the end of amplification, standard melt curve analysis supplemented by the CFX Maestro software was performed to validate amplified targets.

For other qPCR experiments, total RNA was extracted with a RNeasy Plant Mini Kit (Qiagen) according to the manufacturer's instructions. cDNA was prepared from 1 μ g of total RNA with PrimeScript 1st Strand cDNA Synthesis Kit (Takara Bio Inc). Resulting cDNA was diluted 1:9 in ddH₂O and 1 μ L of the resulting dilution used in the PCR reaction. PCR was performed in a 7500 Fast Real-Time PCR System (Applied Biosystems) with SYBR premix ExTaq (Tli RNaseH Plus) Rox Plus (Takara Bio Inc), using the comparative C_T standard program implemented in the 7500/7500 Fast Software according to manufacturer's instructions, including melt curve analysis to validate amplified targets.

Sample reactions were pipetted in triplicates per biological replicate and gene. All relative expression levels were calculated following Hellemans *et al.*⁵⁰, and MpEF1 α (MpELONGATION FACTOR 1 α , Mp3g23400) was used as the reference gene²⁵. Primers are listed in Table S2.

RNA sequencing

For the MpDELLA overexpression data set, WT and *pro35S:MpDELLA-Cit* plants were grown from gemmae on half-strength Gamborg's B5 plates containing 1% sucrose under LD conditions for 30 days. Then whole plants for two biological replicates were collected for total RNA extraction total RNA with a RNeasy Plant Mini Kit (Qiagen) according to the manufacturer's instructions. The

RNA concentration and integrity [RNA integrity number (RIN)] were measured with an RNA nanochip (Bioanalyzer, Agilent Technologies 2100). Library preparation with TruSeq RNA Sample Prep Kit v.2 (Illumina) and sequencing of 75-nt single-end reads on Illumina NextSeq 550 were carried out at the Genomics Service of the University of Valencia.

For the *Mppif^{ko}* dataset, Tak-1 and *Mppif^{ko}* were grown from gemmae on half-strength Gamborg's B5 plates containing 1% sucrose under continuous red-light conditions (50 $\mu\text{mol photons m}^{-2} \text{s}^{-1}$) for 7 days, then irradiated with far-red light (50 $\mu\text{mol photons m}^{-2} \text{s}^{-1}$). Whole plant materials for three biological replicates were collected each at 0, 1, and 4 h after the irradiation. Total RNAs were extracted using RNeasy Plant Mini Kit (Qiagen) and purified with the RNeasy MinElute Cleanup Kit (Qiagen). RNA concentration and qualities were examined by Qubit Assays (Thermo Fisher Scientific) and the Agilent 2100 Bioanalyzer. Libraries were prepared using a TruSeq RNA Sample Prep Kit v.2 (Illumina), quantified by KAPA Library Quantification Kit (Kapa Biosystems), and sequenced of 126-nt single-end reads on Illumina HiSeq 1500 at National Institute for Basic Biology (Okazaki, Japan).

Non-targeted flavonoid-related metabolite profiling

Analysis of secondary metabolites in freeze-dried *Marchantia* samples was carried out following a non-targeted approach as previously described⁵¹. Briefly, samples (c.a. 10 mg) were extracted in 80% aqueous MeOH containing biochanin A at 1 mg L⁻¹ (Sigma-Aldrich, Madrid, Spain) as internal standard by ultrasonication for 10 min. Crude extracts were centrifuged and clean supernatants recovered and filtered through PTFE 0.2 μm syringe filters directly into dark chromatography vials. Extracts were injected into a UPLC system (10 μL) (Acquity SDS, Waters Corp. Ltd. USA) and separations carried out on a C18 column (Luna Omega Polar, C18, 1.6 μm , 100 \times 2.1 mm, Phenomenex, CA, USA) using acetonitrile and ultrapure water, both supplemented with formic acid at a concentration of 0.1% (v/v), as solvents at a flow rate of 0.3 mL min⁻¹. A gradient elution program starting from 5% to 95% acetonitrile in 17 min followed by a 3 min re-equilibration period was employed. Compounds were detected by mass spectrometry using a hybrid quadrupole time-of-flight mass spectrometer (QTOF-

MS, Micromass Ltd., UK) coupled to the UPLC system through an electrospray source. Samples were analyzed in both positive and negative electrospray modes within 50-1000 Da mass range using two simultaneous acquisition modes: 1) low CID energy for profiling purposes and 2) high CID energy for MS/MS of selected compounds, this was achieved by setting an energy ramp from 5-60 eV. During measurements cone and capillary voltages were set at 30 V and 3.5 kV, respectively; source and block temperatures were kept at 120°C. Desolvation gas (N₂) was kept at 350 °C at a flow rate of 800 L h⁻¹. Nebulization gas was also N₂ at a flow rate of 60 L h⁻¹. In the collision cell, pure Ar was used as the collision gas. Exact mass measurements were achieved by monitoring the reference compound lockmass leucine-enkephalin ([M+H]⁺ 556.2771 and [M-H]⁻ 554.2514, respectively); therefore, the resulting mass chromatograms were acquired in centroid mode.

Analysis of survival after oxidative stress

For survival measurement, 10 gemmae per genotype and experiment were grown on top of Whatman filter papers discs (Thermo Fisher) on half-strength Gamborg's B5 1% agar medium for 6 days, and then transferred to half-strength Gamborg's B5 1% agar medium supplemented with 100 µM methyl viologen to produce a severe oxidative stress for 10 days. Gemmallings were transferred back to half-strength Gamborg's B5 1% agar medium for recovery. Survival was counted when independent apical regions resumed growth and represented as the percentage of growth-resuming apical regions of the total number at the beginning of the stress treatment.

In *MpDELLA-GR* related assays, the same procedure was followed, but mock and 1 µM dexamethasone (DEX) were included for DELLA activity induction during the 10 days of oxidative stress treatment. In addition, DEX or mock (ethanol) were added in water solution 24 hours before stress treatment.

QUANTIFICATION AND STATISTICAL ANALYSIS

General statistical analyses

Statistical significance for biological samples was analyzed by applying Student's t test in pairwise comparisons, and one-way ANOVA corrected by Tukey HSD (alpha = 0.05) in the case of multiple group comparisons using GraphPad Prism version 8 (<http://www.graphpad.com>). If the number of samples (n) was more than three in each group, Shapiro-Wilk tests were performed to validate the normality of data distribution. The use of each test, as well as number of samples and replicates (technical and/or biological) if applicable, and p-value thresholds to account for statistical significance of each experiment are stated in the figure legend. Graphical depiction of center and dispersion per group sample represents mean and SD unless specified.

Quantification of dividing cells in EdU-labelled tissue

EdU-labelled nuclei were marked and counted with a modified version of the ITCN plugin⁵² in ImageJ 1.52a⁴². Spatial coordinates for the nuclei were exported and processed with R scripts⁵³ to calculate density maps using the *spatstat* package⁵⁴. Actively dividing area was measured as with nucleus densities higher than 0.001 μm^{-2} . See Key Resources Table for the repository of plugins and scripts used.

RNA sequencing data analyses

For RNA-seq data processing, reads from described sources were mapped to the *M. polymorpha* reference genome and quantified using Salmon 1.3.0⁵⁵. Reads from male lines were mapped to the MpTak1 v5.1 genome⁵⁶, while reads from female *Mppif^{ko}* plants were mapped to autosome sequences from MpTak1 v5.1 plus the known U-chromosome scaffolds from genome ver 3.1¹¹. Differential gene expressions between sample pairs were analyzed with the R package DESeq2⁵⁷, in which both autosome and V chromosome genes were considered for the MpDELLA overexpression set, while only autosome genes were compared between Tak-1 and *Mppif^{ko}*. Genes with a minimum fold change of 2 and adjusted p-value smaller than 0.01 were considered as significantly changed in expression. Compared with the wildtype, *pro35S:MpDELLA-Cit* led to the significant up- and down-regulation of 4 and 2 V-chromosome genes,

respectively. The total number of MpTak1 v5.1 autosome genes was used for checking if MpDELLA-regulated genes were enriched in differentially expressed genes caused by Mppi^{#o} using Fisher's exact test. UpSet plots were created using the R package ComplexHeatmap⁵⁸.

Fuzzy Gene Ontology (GO)⁵⁹ annotations for the v5.1 (plus ver 3.1 U-chromosome) genes were generated using the Blast2GO algorithm⁶⁰ written in R scripts. Briefly, all *M. polymorpha* reference proteins were blasted⁶¹ against a database containing all UniProtKB⁶² entries with non-IEA (inferred from electronic annotation) GO annotations, plus all Swiss-Prot entries (release 2020_05) with an e-value threshold of 0.001. Then the GO annotations from top 25 blast hits for each target protein were scored and concatenated based on their similarity and the GO hierarchy (release 2020-06-01). Annotations with scores higher than the user-defined thresholds (40 for cellular component, 55 for biological process, 50 for molecular function) were transferred to *M. polymorpha* proteins. GO enrichment analysis was conducted with biological process terms with the classic fisher's test from the *topGO* package⁶³. R packages *GO.db*⁶⁴, *Rtsne*⁶⁵, *GOSemSim*^{66,67}, *rrvgo*⁶⁸ and *AnnotationForge*⁶⁹ were used for the clustering and visualization of top-enriched GO terms. Repositories for the raw sequence datasets, GO annotations and R scripts are listed in the Key Resources Table and the results are summarized in Data S1.

Metabolite profiling data processing

Processing of mass chromatograms was performed with *xcms*⁷⁰ after conversion to mzXML with *MSConvert*⁷¹ using default settings. Chromatographic peak detection was performed using the *matchedFilter* algorithm, applying the following parameter settings: *snr* = 3, *fwhm* = 15 s, *step* = 0.01 D, *mzdiff* = 0.1 D, and *profmeth* = bin. Retention time correction was achieved in three iterations applying the parameter settings *minfrac* = 1, *bw* = 30 s, *mzwid* = 0.05D, *span* = 1, and *missing* = *extra* = 1 for the first iteration; *minfrac* = 1, *bw* = 10 s, *mzwid* = 0.05 D, *span* = 0.6, and *missing* = *extra* = 0 for the second iteration; and *minfrac* = 1, *bw* = 5 s, *mzwid* = 0.05 D, *span* = 0.5, and *missing* = *extra* = 0 for the third iteration. After final peak grouping (*minfrac* = 1, *bw* = 5 s) and filling in of missing features using the *fillPeaks* routine of the *xcms* package, a data matrix consisting

of feature × sample was obtained. When available, identification of metabolites was achieved by comparison of mass spectra and retention time with those of authentic standards or alternatively were tentatively annotated by matching experimental mass spectra in public databases (metlin, Massbank or HMDB). Known and tentative flavonoid-related compounds were chosen for comparison. Before statistical analyses, raw peak area values were normalized to internal standard area and sample weight. Pairwise comparisons were carried out using a two-tailed Student's t-test comparing two groups of samples of identical variance.

KEY RESOURCES TABLE

REAGENT or RESOURCE	SOURCE	IDENTIFIER
Antibodies		
Anti-GFP JL-8	Takara Bio	Cat#632380
Anti-HA-Peroxidase, High Affinity (3F10)	Sigma-Aldrich	Cat#12013819001
Goat anti-Mouse IgM (Heavy Chain) Secondary Antibody, HRP	Thermo Fisher Scientific	Cat#626820
Bacterial and Virus Strains		
<i>Escherichia coli</i> DH5 α	Widely distributed	N/A
<i>Escherichia coli</i> TOP10	Widely distributed	N/A
<i>Agrobacterium tumefaciens</i> GV3101 (pMP90 C58)	40	N/A
<i>Agrobacterium tumefaciens</i> GV2260	41	N/A
Chemicals, Peptides, and Recombinant Proteins		
Gamborg's B5 salts	35	N/A
Chlorsulfuron	Sigma-Aldrich	Cat#N11461
Chlorsulfuron (Glean XP)	Dupont	EPA#352-653
Hygromycin B	PanReac AppliChem	Cat#A2175-0005
Hygromycin B	Nacalai Tesque	Cat#07296-24
Cefotaxime sodium	Duchefa Biochemie	Cat#C0111.0005
Cefotaxime (CLAFORAN)	Sanofi	Cat#6132409D1050
3,5-Dimethoxy-4-hydroxyacetophenone (Acetosyringone)	Sigma-Aldrich	Cat#D134406
Dexamethasone (DEX)	Sigma-Aldrich	Cat#D4902
Dexamethasone (DEX)	Fujifilm Wako	Cat#041-18861
Albumin, bovine (BSA)	Nacalai Tesque	Cat#08777-36
3-Amino-1,2,4-triazole	Sigma-Aldrich	Cat#A8056-100G
Methyl viologen dichloride hydrate	Sigma-Aldrich	Cat#856177
5-bromo-4-chloro-3-indolyl- β -D-glucuronic acid (X-Gluc)	Carbosynth	Cat#B-7300
Diphenylboric acid 2-aminoethyl ester (DPBA)	Sigma-Aldrich	Cat#358835
MG-132 in Solution	Calbiochem	Cat#474791
cOmplete Protease Inhibitor Cocktail	Sigma-Aldrich	Cat#05056489001
Phenylmethylsulfonyl fluoride (PMSF)	Sigma-Aldrich	Cat#P7626-1G
Biochanin A	Sigma Aldrich	Cat#D2016
LC/MS grade methanol	Fisher Scientific	Cat#A456-212
LC/MS grade acetonitrile	Fisher Scientific	Cat#A/0638/17
LC/MS grade formic acid	Fisher Scientific	Cat#A117-50
Critical Commercial Assays		
Phusion High-Fidelity Polymerase	Thermo Fisher Scientific	Cat#F530L
KOD FX Neo DNA polymerase	Toyobo Life Science	Cat#KFX-201
KOD -Plus- Ver.2 DNA polymerase	Toyobo Life Science	Cat#KOD-211
PrimeSTAR GXL DNA Polymerase	TaKaRa Bio	Cat#R050A
pENTR/D-TOPO Cloning Kit	Thermo Fisher Scientific	Cat#K2400-20
pCR8/GW/TOPO TA Cloning Kit	Thermo Fisher Scientific	Cat#K2500-20
In-Fusion HD Cloning Kit	TaKaRa Bio	Cat#639649
<i>Bsa</i> I	New England Biolabs	Cat#R0535L

EcoR V	TaKaRa Bio	Cat#1042A
Not I	TaKaRa Bio	Cat#1166A
Sal I	TaKaRa Bio	Cat#1080A
T4 DNA ligase	Promega	Cat#M1804
T4 DNA ligase	TaKaRa Bio	Cat#2011A
Ligation high Ver.2 DNA ligase	Toyobo Life Science	Cat#LGK-201
Gateway BP Clonase II Enzyme mix	Thermo Fisher Scientific	Cat#11789-020
Gateway LR Clonase II Enzyme mix	Thermo Fisher Scientific	Cat#11791-020
Click-iT EdU Alexa Fluor 488 Imaging Kit	Invitrogen	Cat#C10337
Protein Assay Dye Reagent Concentrate	BIO-RAD	Cat#500-0006
µMACS GFP Isolation Kit	Miltenyi Biotec	Cat#130-091-125
SuperSignal West FEMTO maximum sensitivity substrate	Thermo Fisher Scientific	Cat#34095
Dual-Glo Luciferase Assay System	Promega	Cat#E2920
TRIzol Reagent	Invitrogen	Cat#15596018
RNeasy Plant Mini Kit	QIAGEN	Cat#74904
RNeasy MinElute Cleanup Kit	QIAGEN	Cat#74204
RQ1 RNase-Free DNase	Promega	Cat#M6101
RNase-free DNase Set Kit	QIAGEN	Cat#74254
ReverTra Ace	Toyobo Life Science	Cat#TRT-101
PrimeScript 1st strand cDNA Synthesis Kit	Takara Bio	Cat#6110A
TaKaRa Ex Taq	Takara Bio	Cat#RR001A
SYBR Green I Nucleic Acid Stain	Lonza	Cat#50513
SYBR Premix Ex Taq	Takara Bio	Cat#RR420W
Bioanalyzer RNA6000 Nano Kit	Agilent Technologies	Cat#5067-1511
Qubit RNA HS Assay Kit	Thermo Fisher Scientific	Cat#Q32852
TruSeq RNA Library Prep Kit v2	Illumina	Cat#RS-122-2001
KAPA Library Quantification Kit	Roche	Cat#KK4824
Luna Omega 1.6 mm Polar C18 100 x 2.1 mm	Phenomenex	Cat#00D-4748-AN
Cytiva Whatman Qualitative Filter Paper: Grade 1 Circles	Fisher Scientific	Cat#10738611

Figure 1

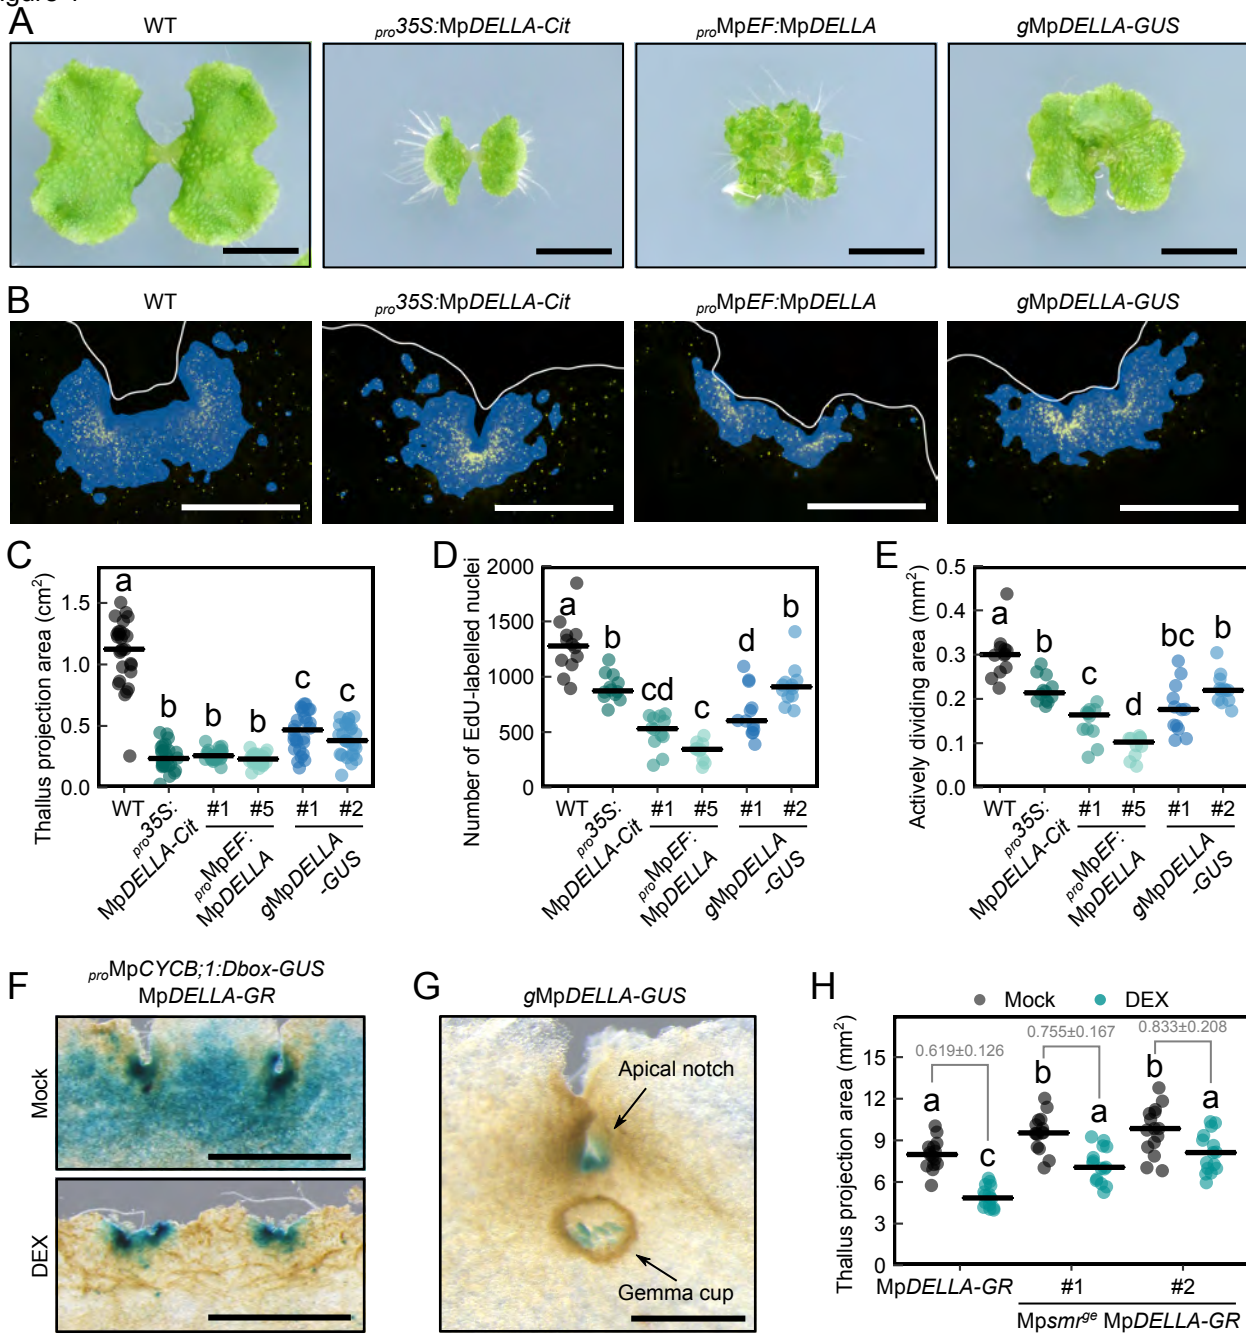

Figure 2

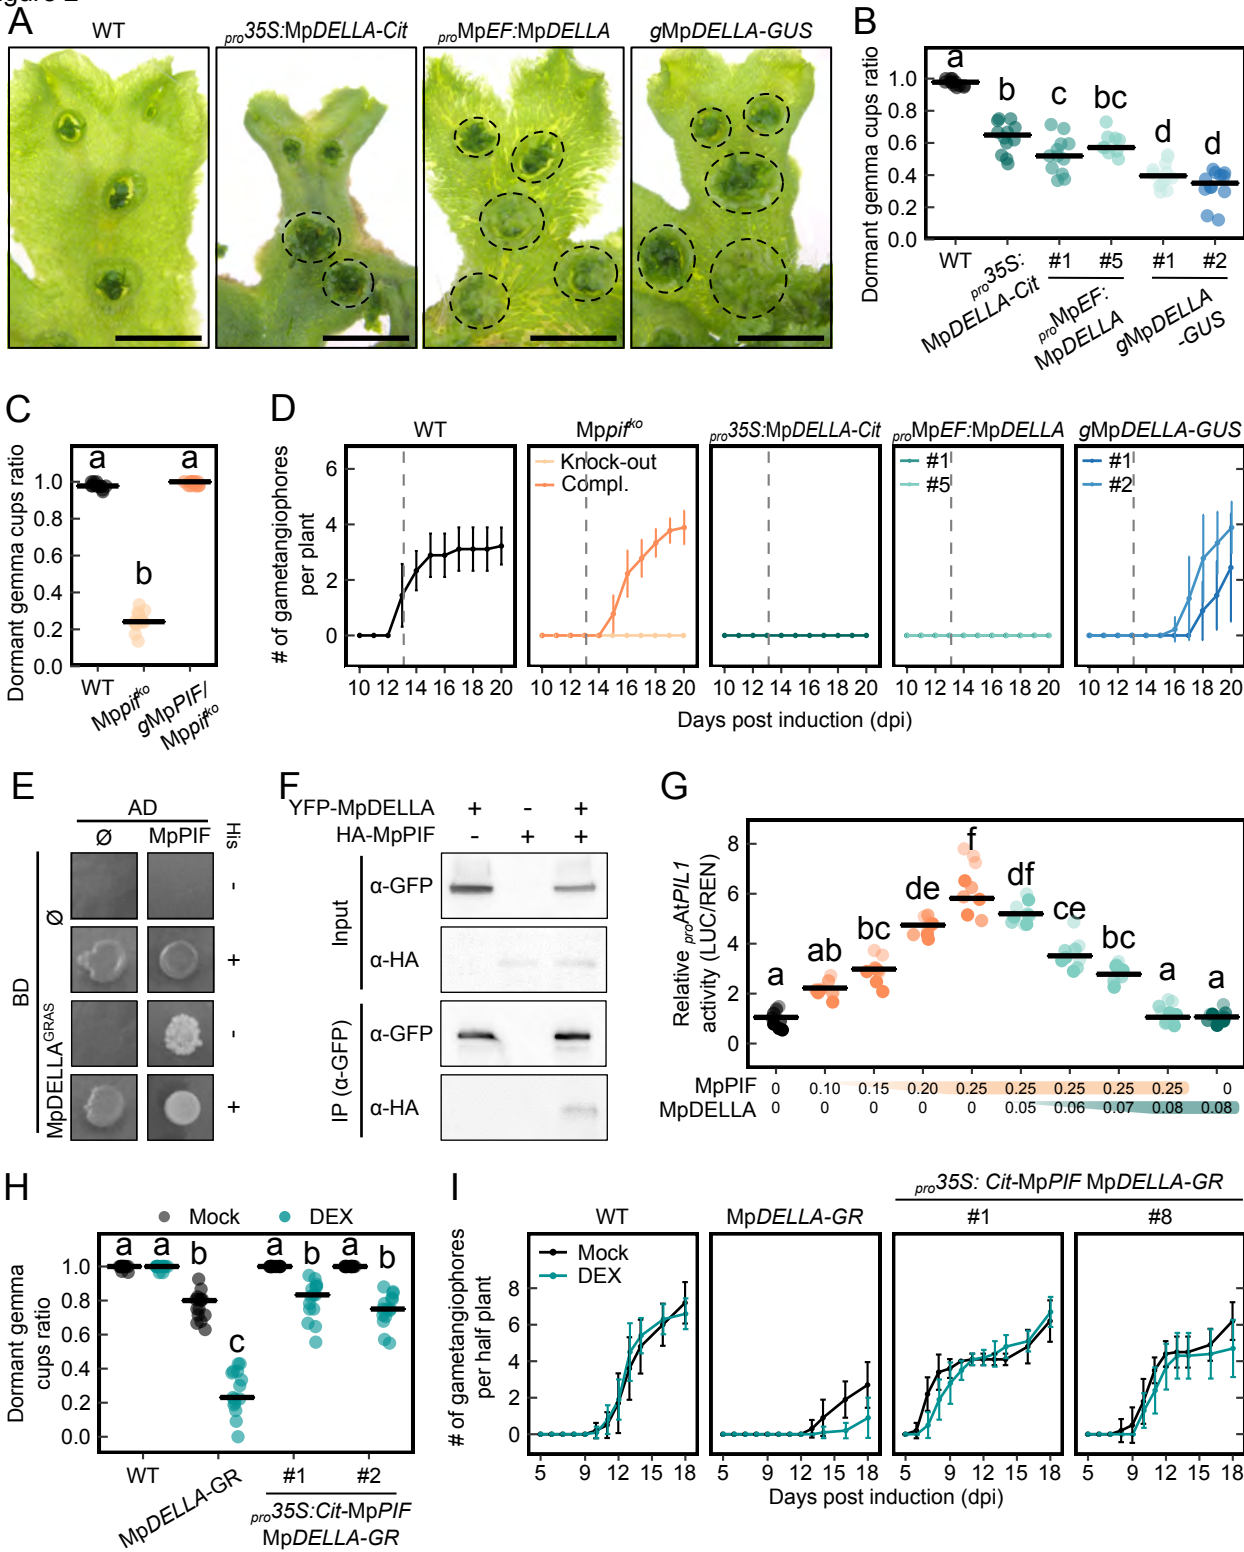

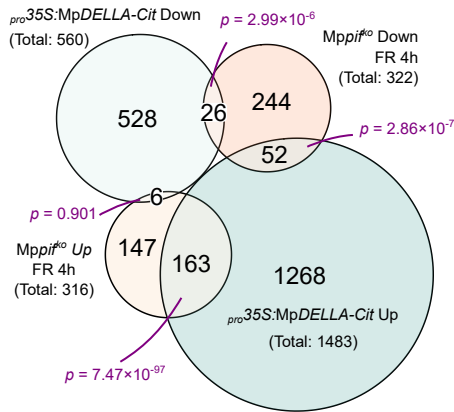

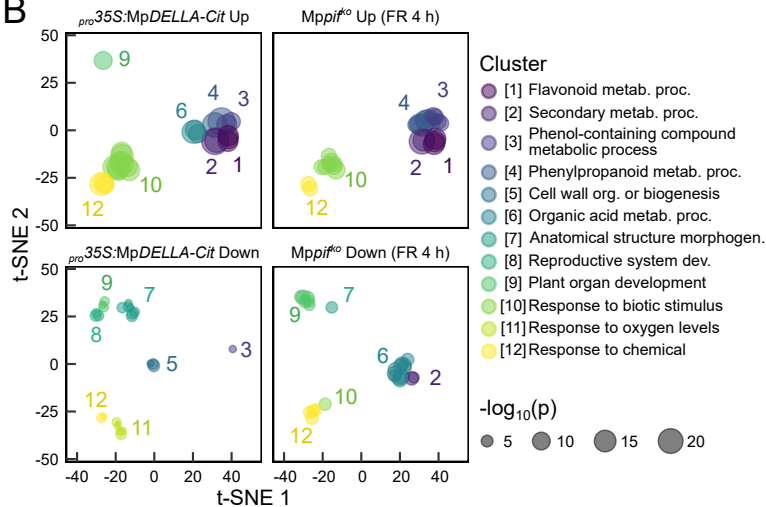

Figure 3

A

B

C

D

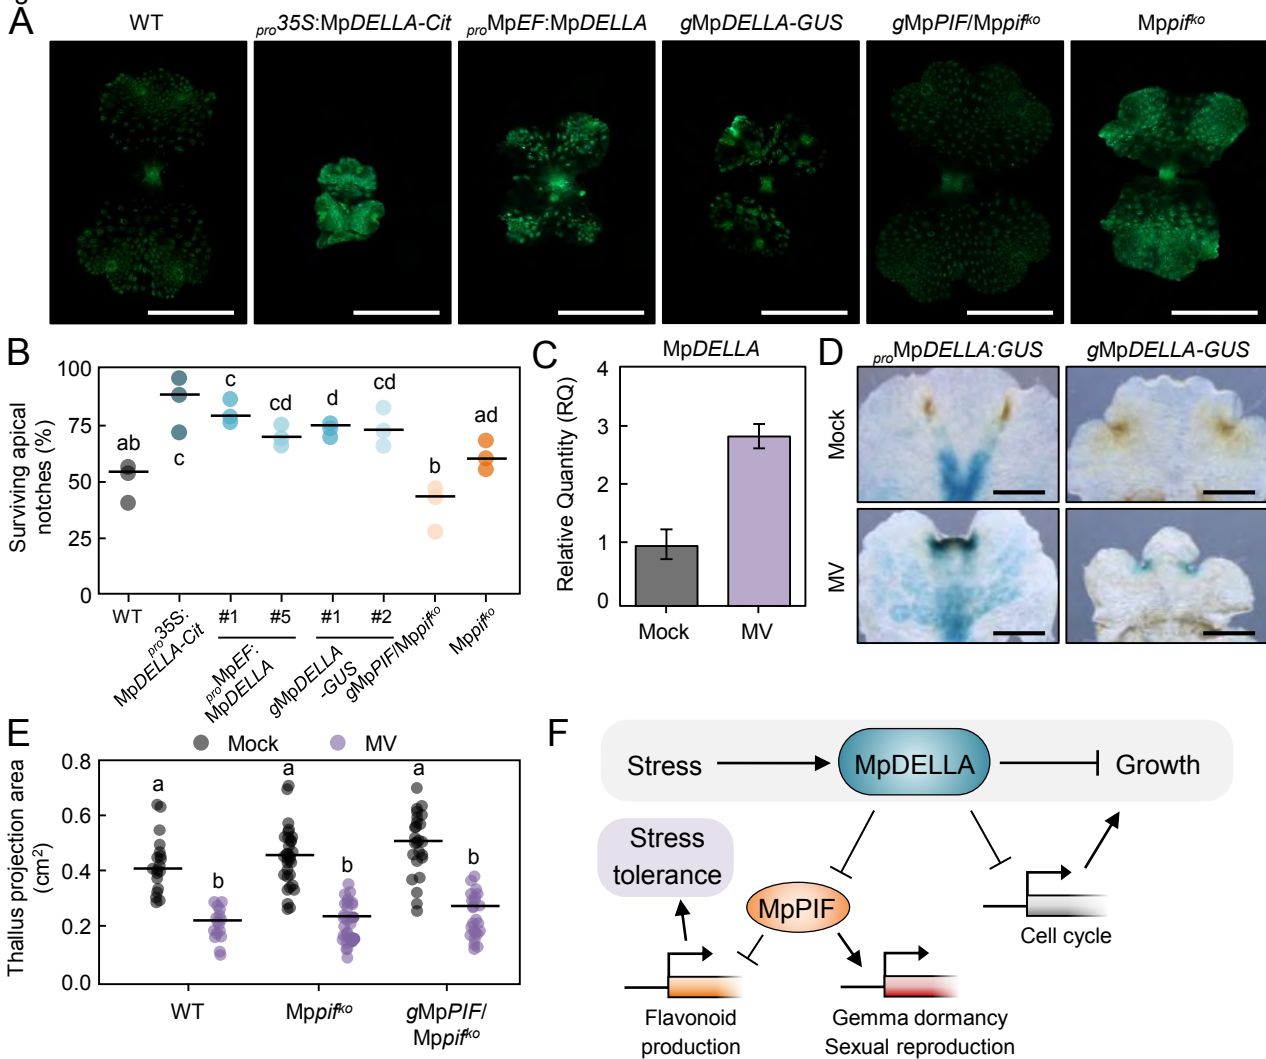

Figure 4

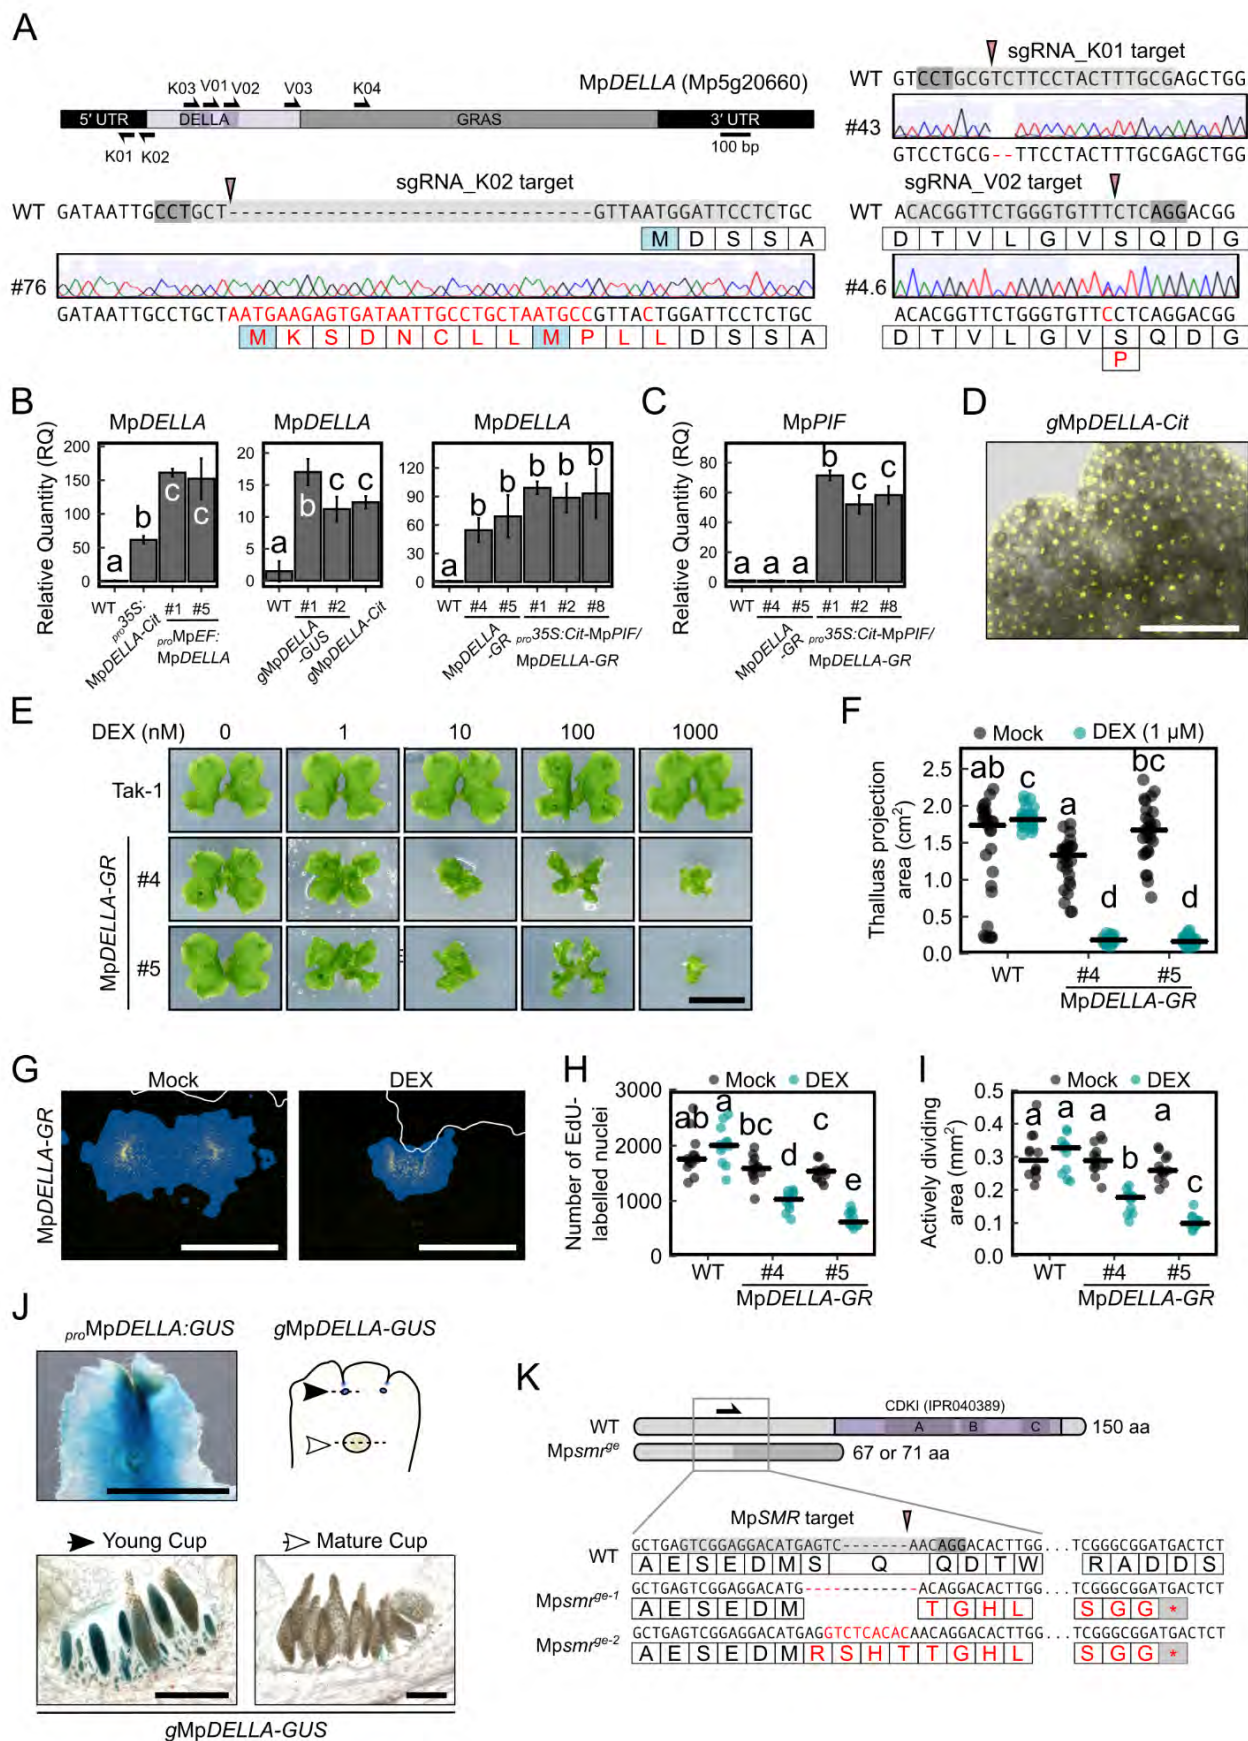

Figure S1. Characterization of transgenic lines involving MpDELLA. Related to Figure 1.

- (A) CRISPR-Cas9 genome editing attempts to obtain a *Mpdella* mutant. Positions of short guide RNA (sgRNA) targets designed independently in Kyoto (K) or Valencia (V) were indicated in the illustration, and chromatograms showed sequencing data for three mutations obtained. #76 from sgRNA_K02 changed the sequences around the start codon but caused no frameshifts. sgRNA_V02 generated the 1-bp substitution in #4.3 in a chimeric manner and was eventually taken over by the wild-type tissue. The 2-bp deletion with sgRNA_K01 was successful but it did not change the coding sequence.
- (B) Relative expression level of *MpDELLA* determined by RT-qPCR in 14-day-old gemmalings.
- (C) Relative expression level of *MpPIF* determined by RT-qPCR in 14-day-old gemmalings of *pro35S:Cit-MpPIF MpDELLA-GR* lines.
- (D) Microscopic image of the apical notch of *gMpDELLA-Cit* gemma showing *MpDELLA-Cit* nuclear localization. Scale bar, 200 μ m.
- (E) Morphology of *MpDELLA-GR* plants, grown from gemmae for 14 days with mock or different concentrations of DEX. Scale bar, 5 mm.
- (F) Measurement of plant sizes in *MpDELLA-GR* gemmalings, grown from gemmae with mock or 1 μ M DEX for 14 days. n=27.
- (G) Apical notches of 7-day-old *MpDELLA-GR* gemmalings, treated with mock or 1 μ M DEX for two days and labelled with EdU (yellow signals). Plant boundaries are marked with white lines, and blue color indicates the area occupied by dividing cells. Scale bar, 500 μ m.
- (H) Number of EdU-labelled nuclei in the apical notches of 7-day-old *MpDELLA-GR* gemmalings, treated with mock or 1 μ M DEX for two days. n=12.
- (I) Quantification of actively dividing area in the apical notches of 7-day-old *MpDELLA-GR* gemmalings, treated with mock or 1 μ M DEX for two days. n=12.
- (J) GUS-stained thallus of 21-day-old *MpDELLA* reporter lines, showing the range of promoter activity across the thallus (*proMpDELLA:GUS*, Scale bar, 5 mm) or *MpDELLA* protein accumulation in developing (black arrow) and mature (white arrow) gemma cups (agar sectionings of *gMpDELLA-GUS*. Scale bars, 200 μ m).
- (K) Genotype information for the *Mpsmr^{ge} MpDELLA-GR* lines. Predicted protein products from wild-type and genome-edited *MpSMR* locus were illustrated (purple boxes: CDKI functional domains; dark-grey shade: frameshifts caused by genome editing). Sequences of wild-type and both CRISPR/Cas9-derived alleles were shown in alignments. In A, B, error bars represent SE (n=3). In E, F, G, dots represent individual plants and horizontal lines represent mean values. Statistical groups were determined by Tukey's Post-Hoc test (p<0.05) after one-way ANOVA.

Figure S2. Physical and functional interaction between MpDELLA and MpPIF. Related to Figure 2.

(A) Images of 28-day-old plants showing premature gemmae germination inside the cups of *Mppif^{ko}* and the complemented line (*gMpPIF/Mppif^{ko}*). Dashed circles indicate non-dormant gemma cups. Scale bar, 5 mm.

(B) Germination frequencies of the wild-type and *MpDELLA-GR* gemmae under different light conditions. Gemmae were imbibed and treated without (Dark) or with a pulse of red light (4500 $\mu\text{mol photons m}^{-2}$) followed by incubation in the dark. Dark grey and turquoise columns represent gemmae supplemented with mock or 1 μM DEX, respectively.

(C) Bimolecular fluorescence complementation assays showing *MpDELLA*-*MpPIF* interaction in *N. benthamiana* abaxial leaves.

(D) Physical interaction between *MpDELLA* GRAS domain and *MpPIF* bHLH domain shown by yeast two-hybrid assays of *MpPIF* deletion fragments. Although there is no conserved APB domain in *MpPIF*, its theoretical position was marked by ψAPB and used for fragmentation. *MpPIF* amino acids present on each fragment are 1-472 (del1), 132-760 (del2), 473-760 (del3) and 588-760 (del4). Histidine (His) supplemented media used as growth control. 5 mM 3-amino-1,2,4-triazole (3-AT) was added to His-depleted medium.

(E) Physical interaction between YFP-*MpDELLA* and HA-*MpPIFdel3* (aa 473-760) shown by co-immunoprecipitation after agroinfiltration in *N. benthamiana* leaves.

(F) Germination frequencies of *MpDELLA-GR* gemmae with additional expression of *MpPIF* (*pro35S:Cit-MpPIF*) under different light conditions as indicated in (B). Dark grey and blue columns represent gemmae supplemented with mock or with 1 μM DEX, respectively.

(G) Morphology of 14-day-old *MpDELLA-GR* and *pro35S:Cit-MpPIF/MpDELLA-GR* plants, grown with different concentrations of DEX. Scale bar, 1 cm.

In B, F, error bars represent standard deviation from three independent experiments (n = 50 per experiment). Statistical groups were determined by Tukey's Post-Hoc test ($p < 0.05$) following ANOVA analysis.

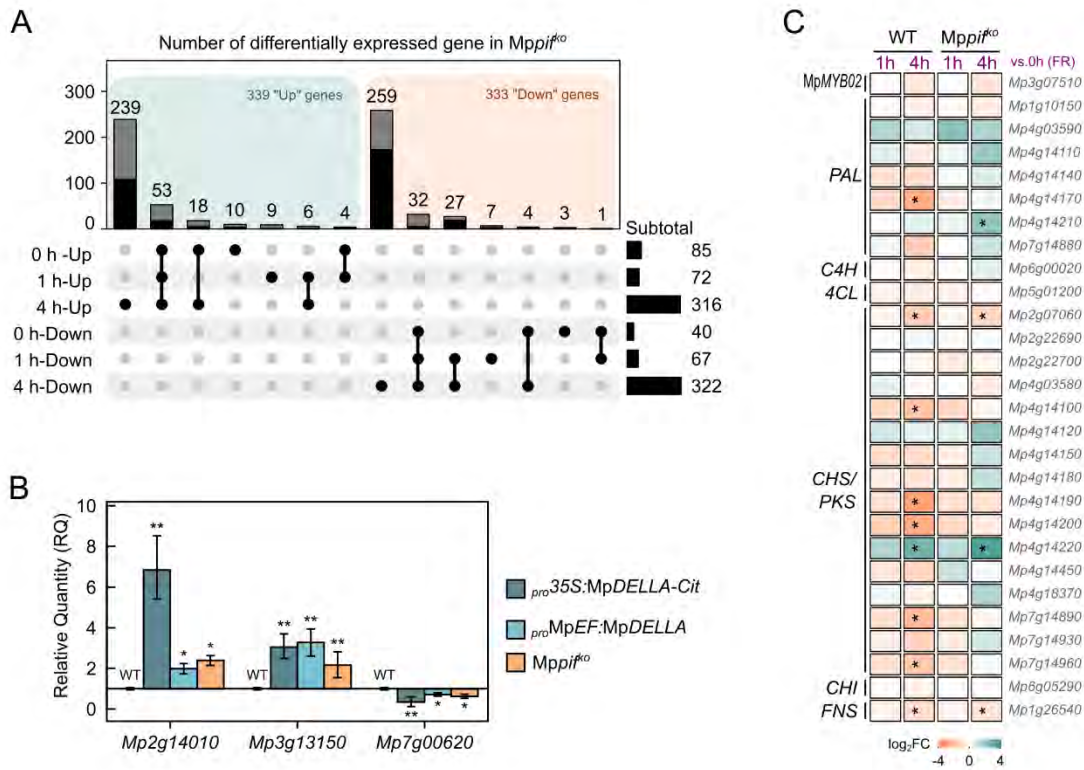

Figure S3. *MpPIF*-dependent gene expression changes in response to far-red light. Related to Figure 3.

(A) UpSet plot showing differentially expressed genes between *Mppif*^{ko} and the wild-type at different time points after far-red light (FR) irradiation. Black proportions in the top column plot represent genes ever changed significantly (with $|\log_2FC| > 1$ and adjusted $p < 0.01$ calculated by DESeq2) in response to far-red treatment in either genotypes.

(B) Relative expression level of selected genes by RT-qPCR, as a verification for the RNA-seqs. Error bars represent standard deviation from three biological replicates. Asterisks indicate statistically significant differences with respect to the wild type (*, $p < 0.05$; **, $p < 0.01$, after a Student's t-test)

(C) Fold changes in expression (\log_2 scale) of genes related to flavonoid biosynthesis, compared to time point 0 in both genotypes. Asterisks indicate genes considered as significantly changed (with $|\log_2FC| > 1$ and adjusted $p < 0.01$ calculated by DESeq2).

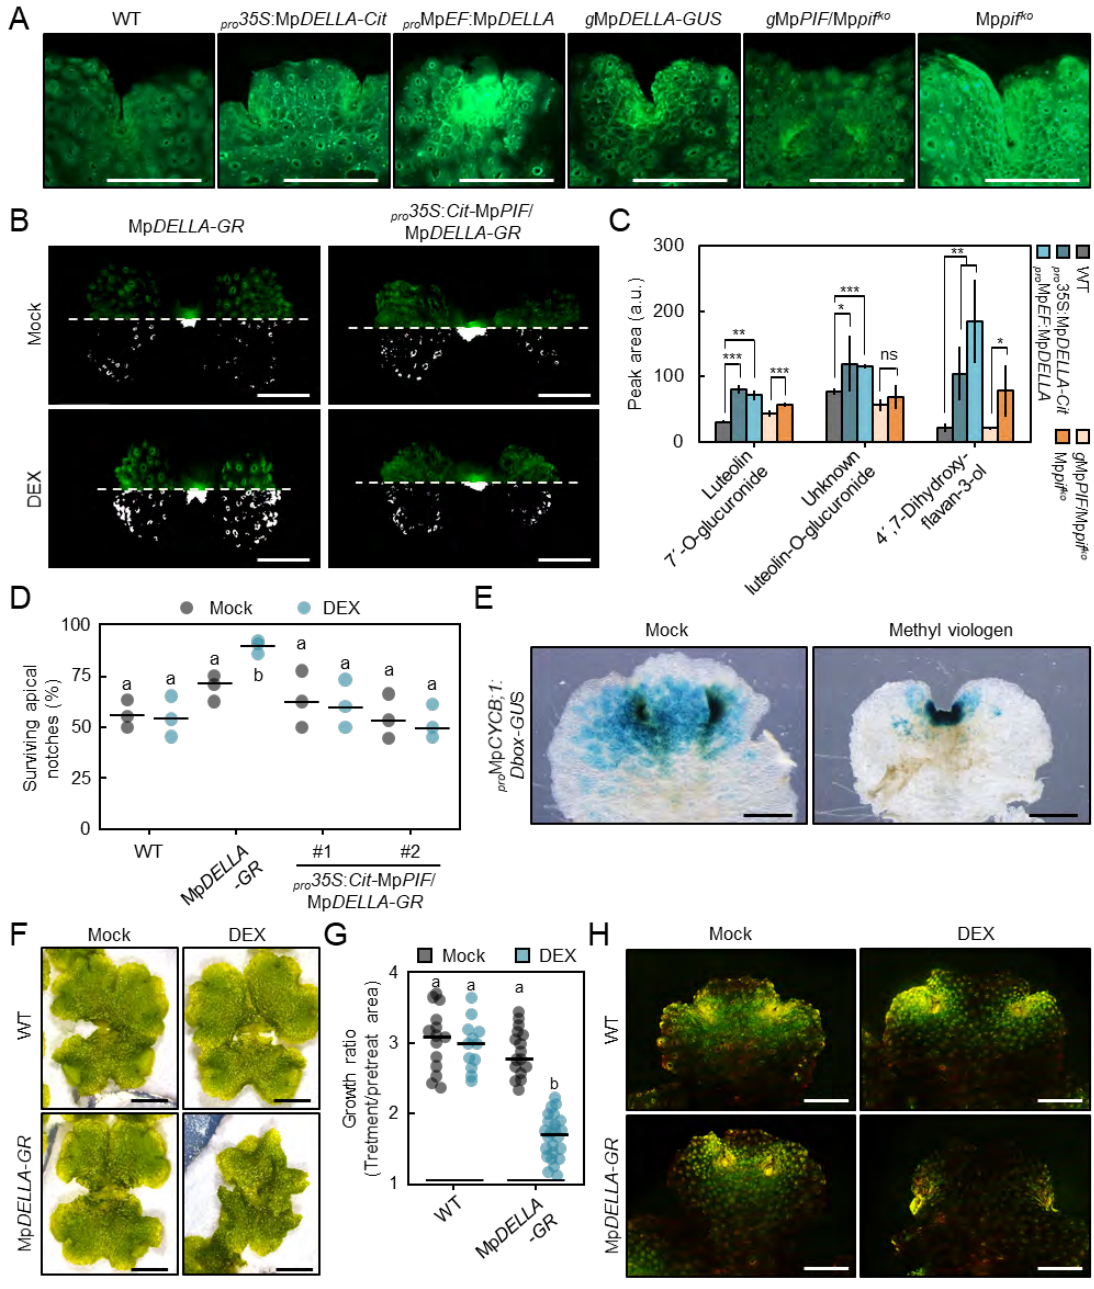

Figure S4. Involvement of MpDELLA in the response to oxidative stress. Related to Figure 4.

(A) Images of apical region of Figure 4A gemmalings, stained by DPBA. More intense fluorescent signals denote higher general flavonoid content. Scale bar, 1 mm.

(B) Images showing DPBA staining of 9-day-old *MpDELLA-GR* and *pro35S:Cit-MpPIF MpDELLA-GR* gemmalings, grown with or without 1 μ M DEX for 3 days. Upper halves, original picture taken with GFP filter; Lower halves, pseudo-color intensity binary maps (threshold at 30%) to facilitate the comparison of the differences in fluorescence signal between images. Scale bar, 2 mm.

(C) Differentially accumulated flavonoid-related compounds in different genotypes as found by untargeted metabolomics analyses. Original data with individually detected ions and parameters of detection can be found in Table S1.

(D) Percentage of surviving apical notches after a 10-day treatment with 100 μ M methylviologen (MV). *MpDELLA-GR* induction with 1 μ M DEX started one day earlier before MV application and was further maintained throughout the stress treatment.

(E) Images of 13-day-old *MpCYCB;1-GUS MpDELLA-GR* plants stained for GUS activity after mock or 10 μ M MV treatment for 6 days. Scale bar, 1 mm.

(F) Morphology of 14 days-old wild-type and *MpDELLA-GR* plants grown for three days after local application of 20 μ M DEX at the apical notch. Scale bar, 4 mm.

(G) Quantification of the growth ratio in F, accounted as the thallus projection area three days after DEX treatment versus thallus projection area the day of application.

(H) Images of DBPA staining showing the effect of apical notch local DEX application in plants identical to those in F. Scale bar, 2 mm.

In C, fold changes and p-values from Student's t-tests are calculated with quantifications from four samples per genotype with the sole exception of Tak-1 (three samples). In D, E dots represent biological replicates and horizontal lines median values from three independent experiments, in G, dots represent individual measurements in two independent experiments, statistical support is provided by one-way ANOVA analysis, and groups determined by Tukey's Post-Hoc test ($p < 0.01$).

Table S2. List of oligonucleotides, related to STAR methods.

^aThe last nucleotide of this primer does not match with the current reference genome, though the amplification was successful and confirmed by sequencing.

Additional overhangs for proper cloning (Gateway/restriction site/sticky end) are marked in red; start codons are underlined.
