10

11 **Abstract**

12 *Psyllium* fibre has known health benefits, which are highly related to its gelling properties,
13 so it is important to know the functional properties and its gelling capacity to its possible
14 incorporation as a new source of DF in foods. Therefore, the purpose of this research
15 was to evaluate these properties of two *Psyllium* fibres. Physicochemical (particle size
16 distribution, pH, water content, water activity, hygroscopicity and bulk density and
17 porosity), hydration (water holding, water retention and swelling capacity, fat absorption
18 capacity and solubility), and nutritional properties (mineral content, total phenolics
19 compounds and antioxidant capacity) of dietary fibre (DF) samples were recorded.
20 Moreover, physicochemical (water content, pH and colour) and mechanical properties
21 (back extrusion test, rheological measurement and texture profile analysis) of gel
22 samples were performed before and after heat treatment (20 min at 65 °C). The hydration
23 properties of Plantago Husk (PH) were higher than those in Plantago Powder (PP), but
24 in functional terms, high values of phenols and antioxidant activity were found in PP.
25 However, both samples displayed similar gelling properties. As a result of the rheological
26 and textural analysis, both fibres showed good gelling properties at both high (65 °C)
27 and cool (5 °C) temperatures, at concentrations 4% to 7%. Moreover, the results indicate

28 that PH and PP have suitable characteristics to be functional ingredients, which can help
29 to avoid possible negative effects on food sensory and structural characteristics.

30

31 **Keywords:** *Psyllium* fibre; hydration properties; functional capacity; gelling properties.

32

33 1. INTRODUCTION

34 There is a growing awareness about diet and health, which has brought about changes
35 in consumer eating habits and the demand for healthier foods has increased (de Moraes
36 Crizel, Jablonski, de Oliveira Rios, Rech, & Flôres, 2013). Fibre was one of the first
37 ingredients to be associated with health in the 1980s and has been used by the food
38 industry ever since (Dervisoglu, & Yazici, 2006; de Moraes Crizel et al., 2013). Plants
39 high in dietary fibre (DF) and natural antioxidants have drawn increasing attention in
40 recent years (Zhu, Huang, Peng, Qian, & Zhou, 2010). DF consumption offers several
41 health benefits, including body weight control, reduced serum lipid and cholesterol,
42 controlled postprandial glucose responses and colon cancer prevention, which are
43 attributed to the physicochemical and functional properties of DF (Ma, & Mu, 2016). DFs
44 also have well-known technological functions, such as water absorption and water
45 retention and can, thus, reduce shrinkage, cooking loss and drip loss during storage, and
46 can minimise production costs without affecting final products' sensory properties (Han,
47 & Bertram, 2017). Thus the emergence of new fibre sources and processing methods to
48 improve fibre's functionality has extended its applications in the food industry. Further,
49 they have opened new possibilities to design new fibre-enriched products and generate
50 new textures for a variety of applications (Rosell, Santos, & Collar, 2009).

51 *Psyllium* seed husk (*Plantago ovata*) is a source of natural DF that is of interest for food
52 and pharmaceutical sciences as a functional ingredient (Ren, Linter, & Foster, 2020a). It
53 comprises arabinoxylan, a polymer rich in arabinose and xylose, whose digestibility in
54 humans is limited (Jalanka et al., 2019). *Psyllium* has been used in traditional medicine
55 worldwide (Fradinho, Soares, Niccolai, Sousa, & Raymundo, 2020; Ren, Yakubov,
56 Linter, MacNaughtan, & Foster, 2020b). Ren et al. (2020b) and Franco, Sanches-Silva,
57 Ribeiro-Santos, and Ramos de Melo (2020) have reported that *Psyllium* husk seed has
58 good water absorbability with gelling properties, and can be used as a hydrocolloid for
59 functional applications in food production. Hydrogels in food are mostly applied for
60 structuring purposes to gain desirable rheological or textural properties, and for

61 stabilising foams, dispersions, emulsions and particles. In recent years, hydrogels have
62 drawn attention for their applications to deliver food bioactives (Mao, Lu, Cui, Miao, &
63 Gao, 2020). Much research has been conducted into *Psyllium* health benefits for
64 diabetes, constipation, colon cancer prevention, diarrhoea, inflammatory bowel disease
65 (ulcerative colitis), irritable bowel syndrome symptoms, abdominal pain, obesity and
66 hypercholesterolaemia (Guillon & Champ, 2000; Jane, McKay, & Pal, 2019; Franco et
67 al., 2020; Belorio, Marcondes, & Gómez, 2020, Ren et al., 2020b). It also contributes to
68 satiety, hypocholesterolaemia and prebiotics (Jalanka et al., 2019; Fradinho et al., 2020;
69 Franco et al., 2020).

70 It is important to point out that the purpose of this research was to carry out a simpler
71 and more practical characterisation of different commercial *Psyllium* than those found in
72 the literature (Fischer et al., 2004; Yin et al., 2012; Benaoun et al., 2017; Patel, Tanna,
73 Mishra & Jha, 2018; Patel et al., 2019) to facilitate the choice and its possible application
74 by companies in the development of new products and modification of existing ones.

75 In order to determine *Psyllium* fibre applications, it is vital to characterise and evaluate
76 them according to their functional properties. So this study aimed to characterise two
77 commercial *Psyllium* fibres to know their physicochemical properties, phenol content,
78 antioxidant properties and mineral contents, and to characterise the physicochemical,
79 textural and rheological gels that form to elucidate their potential use in food products.
80 This characterisation could help to avoid possible negative effects on food sensory and
81 structural characteristics, and also to provide new textures to develop new foods.

82

83 **2. MATERIAL AND METHODS**

84 **2.1. Samples**

85 Two *P. ovata* samples were herein used: Plantago Powder (PP) and Plantago Husk
86 (PH). All these samples were supplied by Productos Pilarica S.A. (Paterna, Spain). The
87 names, ingredients and proximate composition of the samples are shown in Table 1 and
88 Fig. 1.

89

90 **2.2. *Psyllium* samples analysis**

91 All the *Psyllium* samples were analysed in triplicate for each analysis.

92

93 **2.2.1. Particle size distribution**

94 Sample particle size distribution was determined by applying the laser diffraction method
95 and Mie theory following the ISO13320 regulation (AENOR 2009) in a particle size
96 analyser (Malvern Instruments Ltd., Mastersizer 2000, UK) equipped with a dry sample
97 dispersion unit (Malvern Instruments Ltd., Scirocco 2000). The volume (in percent)
98 against particle size (in micrometres) was obtained and the size distribution was
99 characterised by the volume mean diameter (D[4,3]). The standard percentiles d(0.1),
100 d(0.5), and d(0.9) represent the particle size below which 10%, 50% and 90% of the
101 sample lies, respectively. These parameters were estimated by the Mastersizer 2000
102 software (version 5.6) considering the particle diameter.

103

104 **2.2.2. Water content and water activity**

105 Water content (x_w) (g water/100 g sample) was determined by vacuum oven drying
106 (Vaciotem, J.P. Selecta, Spain) at 70 °C until constant weight (AOAC, 2000). Samples'
107 water activity (a_w) was analysed by the AquaLab PRE LabFerrer equipment (Pullman,
108 USA).

109

110 **2.2.3. pH**

111 Samples' pH was measured upon dispersions (10% w/v) of samples in distilled water
112 following described methods (Bender et al., 2020).

113

114 **2.2.4. Hygroscopicity**

115 Samples (about 0.2 g in a Petri dish) were placed at 25 °C in an airtight plastic container
116 with Na₂SO₄ saturated solution (81% RH). After 1, 5, and 7 days, each sample was

117 weighed and hygroscopicity (Hg) was expressed as g of water gained per 100 g dry
118 solids (Cai & Corke, 2000).

119

120 **2.2.5. Bulk density and porosity**

121 The porosity (ϵ), or percentage of air volume related to the total volume, was calculated
122 from the true (ρ) and bulk (ρ_b) densities using $\epsilon = (\rho - \rho_b) / \rho$ according to Igual, García-
123 Segovia and Martínez-Monzó (2021). Samples' real density was determined by a helium
124 pycnometer (AccPyc 1330, Micromeritics, Norcross, USA). For the bulk density (ρ_b)
125 determination, about 2 g of the powder were placed inside a 10 mL graduated test tube
126 and the occupied volume was noted. Bulk density was calculated by dividing the powder
127 mass by occupied volume, expressed as g/L.

128

129 **2.2.6. Determination of hydration properties**

130 Water-holding capacity (WHC) and water retention capacity (WRC) were determined as
131 described by Raghavendra, Rastogi, Raghavarao, and Tharanathan (2004) and by
132 Chantaro, Devahastin, and Chiewchan (2007). WHC and WRC were determined by
133 placing 1 g of sample in a calibrated cylinder and then adding 30 mL of distilled water.
134 Samples were hydrated for 18 h at 25 °C. WRC tubes were centrifuged at 3,000 $\times g$ for
135 20 min. Finally for both determinations, supernatants were removed, and the hydrated
136 residues were weighed and dried at 100 °C for 3 h until constant weight. The results
137 were expressed as g water/g dry sample.

138 Swelling water capacity (SWC) was determined as described by Navarro-González,
139 García-Valverde, García-Alonso, & Periago (2011) with slight modifications. One gram
140 of sample was placed in a graduated test tube and hydrated with 20 mL of distilled water.
141 The sample was stored for 18 h at 25 °C, and then the bed volume was recorded. SWC
142 was expressed as volume mL/g sample.

143 The water solubility index (WSI) was established by the method of Mahdavi, Jafari,
144 Assadpour, and Ghorbani, (2016) with slight modifications. Samples (approx. 1 g) were

145 mixed in centrifuge tubes with 30 mL of distilled water for 5 min until mixtures became
146 homogeneous. Solutions were then incubated at 37 °C in a water bath for 30 min.
147 Afterwards, tubes were centrifuged at 17,640 ×g for 20 min at 4 °C. Supernatants were
148 collected and dried in an oven at 100 °C until constant weight. The results were
149 expressed as a percentage.

150 Following the method reported by Navarro-González et al. (2011) with minor
151 modifications, fat adsorption capacity (FAC) was determined. Samples (4 g) were placed
152 in a centrifuge tube with 24 g of sunflower oil. Contents were stirred for 30 sec every 5
153 min for 30 min. Later samples were centrifuged at 1,600 ×g for 25 min. Free oil was
154 decanted and FAC was expressed as g oil/g sample.

155

156 **2.2.7. Ash and mineral content**

157 The method 930.05 of AOAC procedures (Horwith, & Latimer, 2005) was used to
158 determine the total ash content. A sample (500 mg) was incinerated at high pressure in
159 a microwave oven (Muffle P Selecta Mod.367PE) for 24 h at 550 °C, and ash was
160 gravimetrically quantified.

161 The multiminer determination was made in an inductively coupled plasma optical
162 emission spectrometer, model 700 Series ICP-OES of Agilent Technologies (Santa
163 Clara, USA), with axial viewing and a charge coupled device detector as described in
164 García-Segovia, Igual, Noguero, and Martínez-Monzo (2020). Mineral compositions
165 (macro- and microelements) were expressed as mg/100 g sample.

166

167 **2.2.8. Total phenolic compounds**

168 The extraction of total phenols (TP) comprised homogenising a sample with methanol
169 and HCL (6N), and then centrifuging according to Tomás-Barberán, et al. (2001). TP
170 were quantified by the method of Selvendran, and Ryden (1990) and Benzie, and Strain
171 (1999) based on the Folin-Ciocalteu method. Absorbance was measured at 765 nm in a
172 UV-visible spectrophotometer (Thermo Electron Corporation, USA). Total phenolic

173 content was expressed as mg of gallic acid equivalents (GAE) (Sigma-Aldrich, Germany)
174 per 100 grams of sample using a standard curve 0-800 mg range of gallic acid /mL.

175

176 **2.2.9. Antioxidant capacity**

177 Antioxidant capacity (AC) was assessed using the free radical scavenging activity of the
178 samples evaluated with stable radical 1,1-diphenyl-2-picrylhydrazyl (DPPH) (Sánchez-
179 Moreno et al., 2003) following the methodology of Igual et al. (2016). A UV-visible
180 spectrophotometer (Thermo Electron Corporation, USA) was used to measure
181 absorbance at 515 nm. The percentage of DPPH was calculated in the same way as
182 other authors (Igual et al., 2019). The final results were expressed as milligram Trolox
183 equivalents (TE) per 100 grams of sample (mg TE/100 g) using a Trolox calibration curve
184 within the 10-500 mg/L range (Sigma-Aldrich, Germany).

185

186 **2.3. Preparation of gels**

187 In order to prepare the gel samples, fibre powders were dissolved in cold water (5 °C)
188 for 30 min at the 1, 2, 3, 4, 5, 6 and 7% concentrations. Then samples were divided into
189 two batches. One of them was directly stored under cold conditions (24 h at 5 °C) until
190 gel stabilisation. However, the other batch was subjected to heat treatment at 65 °C for
191 20 min before being stored at 5 °C for 24 h. After storing them, samples were tempered
192 at 25 °C before carrying out the analysis.

193

194 **2.4. Gel analysis**

195 **2.4.1. Water content and pH**

196 Water content (x_w) (g water/100 g sample) was performed as in the powder fibres.

197 The gel samples' pH determined with a pH-meter Crison MultiMeter MM 41 (Hach Lange,
198 Spain).

199

200 **2.4.2. Colour**

201 In order to determine gel colour, the CIE*L*a*b* colours were measured according to
202 García-Segovia et al. (2020) with a Konica Minolta CM-700d colorimeter (Konica Minolta
203 CM-700d/600d series, Tokyo, Japan). Measurements were taken on white and black
204 backgrounds by taking D65 as a standard light and 10° as a standard observer. In order
205 to determine samples' translucency, the Kubelka–Munk theory for multiple scattering to
206 the reflection spectra was applied (Talens, Martinez-Navarrete, Fito, & Chiralt, 2002).
207 The calculated reflectance of an infinitely thick layer of a material was used to obtain
208 samples' coordinate CIE*L*a*b* parameters that presented translucency.

209

210 **2.4.3. Back extrusion test**

211 A back extrusion test was performed according to the method described by Cevoli et al.
212 (2013) with minor modifications. Textural characteristics were evaluated at all the sample
213 concentrations (1-7%) by a TA-XT2 Texture Analyser (Stable Micro Systems Ltd,
214 Godalming, UK) equipped with an extrusion disc (25.4 mm in diameter) positioned
215 centrally over the sample plastic container (diameter: 50 mm, height: 75 mm) with 40 g
216 of sample (approximately 30 mm height). The test was performed at a depth of 50% at
217 the 1 mm/s test speed. The attributes calculated from the force-deformation curve were
218 consistency (N s) (area under the curve up), firmness (N) (maximum force),
219 cohesiveness (N) (maximum negative force) and viscosity (N s) (resistance to flow off
220 the disc).

221

222 **2.4.4. Rheological measurements**

223 Flow curves were performed only at the 4, 5, 6, and 7% concentrations, at which the
224 consistency results of the back extrusion test were lower than 100 N s, as measured by
225 a Kinexus pro⁺ rotational rheometer (Malvern Instruments, Worcestershire, UK) and the
226 rSpace software, equipped with a system of coaxial cylinders (C25/PC25). A sample (20
227 mL) was loaded in the geometry and rested to equilibrate for 3 min to achieve a

228 temperature equilibrium (25 °C) and stress relaxation in a heat-controlled sample stage
229 (Peltier Cylinder Cartridge, Malvern Instruments, Worcestershire, UK). According to the
230 method described by Cevoli et al. (2013) with slight modifications, samples were
231 exposed to a logarithmically increase shear rate from 0 to 200 s⁻¹ in 3 min. Flow curves
232 were evaluated using the *Ostwald -de Waele* (Eq. (1)) rheological model, where σ is the
233 shear stress (Pa), γ is the shear rate (s⁻¹), k is the consistency coefficient (Pa sⁿ) and n
234 the flow behaviour index (dimensionless). This model is used to describe flows of
235 rheologically complex fluids (Shapovalov, 2017). The apparent viscosity at the 50 s⁻¹
236 shear rate (η_{ap}) were calculated (Ribes, Peña, Fuentes, Talens, & Barat, 2020). Each
237 flow curve was performed in triplicate at each sample concentration.

238

$$239 \quad \sigma = k \gamma^n \quad \text{Eq. (1)}$$

240

241 **2.4.5. Texture profile analysis (TPA)**

242 The texture profile analysis (TPA) was performed only on the sample concentrations
243 from 4% to 7%, which presented consistency over 100 N s. Forty grams of each gel
244 preparation concentration were weighed inside a cylindrical plastic container (diameter:
245 50 mm, height: 75 mm). Gel structures were removed from the container before the
246 analysis, which was performed by a TA-XT2 Texture Analyser (Stable Micro Systems
247 Ltd, Godalming, UK) and the Texture Exponent software (version 6.1.12.0). Following
248 the method described by Ađar et al. (2016), a double compression cycle test was run up
249 to 50% strain compression of the original portion height using an aluminium cylinder
250 probe (diameter: 75 mm).

251

252 **2.5. Statistical analysis**

253 An analysis of variance (ANOVA), with a confidence 95% level ($p < 0.05$), by the
254 Statgraphics Centurion XVII Software, version 17.2.04, was applied to evaluate

255 differences in samples. A correlation analysis of all the studied parameters with a 95%
256 significance level was carried out (Statgraphics Centurion XVII).

257

258 **3. RESULTS AND DISCUSSION**

259 **3.1. Psyllium fibres analysis**

260 **3.1.1. Physicochemical properties**

261 Particle size distribution is an important parameter that determines fibre functionality and
262 role in the digestive tract (transit time, fermentation, and faecal excretion) (Rosell,
263 Santos, & Collar, 2009). Fig. 2 shows the particle size distribution in all the samples; as
264 we can see, these samples vastly differed. PH presented the highest particle size,
265 between 40 and 1,660 μm , but with a narrow range of particles between 40 and 105 μm .
266 The particle size for PP was lower, and was distributed from 3 to 631 μm , and
267 concentrated mostly between 40–631 μm . Table 2 shows the volume mean diameter
268 ($D[4,3]$) and the standard percentiles $d(0.1)$, $d(0.5)$, and $d(0.9)$ of samples' particle size.
269 These differences in the samples' particle size distribution implied that the differences in
270 $D[4,3]$, $d(0.1)$, $d(0.5)$ and $d(0.9)$ were significant ($p < 0.05$).

271 Table 2 shows the physicochemical properties (a_w , x_w , pH, and Hg); significant
272 differences in a_w and x_w were found between samples ($p < 0.05$). According to the a_w
273 values of by the tested samples, PP presented the lowest a_w , which are similar to those
274 found by de Moraes Crizel et al. (2013). According to Fernández-López et al. (2009), the
275 ideal a_w to avoid microorganism growth and degradation reactions in products with a low
276 water content is between 0.11 and 0.40. Both our tested samples fell within this range.
277 PH showed the highest x_w , with a value of 5.93 (0.14) $\text{g}_w/100 \text{ g}$ sample. These values
278 are like some commercial DF of the different sources found by Rosell, Santos, and Collar
279 (2009), but were lower than those shown by Chong, Ball, McRae, and Packer (2019) for
280 *Psyllium* husk (10.53 $\text{g}/100 \text{ g}$). The samples' pH values were similar, but significant
281 differences were seen between them ($p < 0.05$). PP had a significantly higher pH than
282 PH ($p < 0.05$). The hygroscopicity (Hg) of PH was significantly higher than PP ($p < 0.05$).

283 In storage terms, lower hygroscopicity could be more positive given the importance of its
284 flowability factor (Moghbeli, Jafari, Maghsoudlou, & Dehnad, 2020).
285 The bulk density (ρ_b) and porosity (ϵ) of the samples are presented in Table 2. The
286 samples with a lower ρ_b had a higher ϵ , and *vice versa*. In addition, small, but significant
287 differences were found for these parameters ($p < 0.05$). The sample with the lowest ρ_b
288 was PH. Lan et al. (2012) reported lower ρ_b values for *Polygonatum odoratum*, but they
289 were similar to cellulose (0.38 g/mL). In addition, there were significant Pearson
290 correlations among ρ_b with D[3,4], d(0.1), d(0.5), and d(0.9) ($p < 0.05$) being -0.9888, -
291 0.9855, -0.9876, and -0.9905, respectively. Therefore, the lower D[4,3], d(0.1), d(0.5),
292 and d(0.9) the higher ρ_b because a fibre with a low bulk density should show more
293 surface area and polar groups, which could make both its swelling capacity and oil-
294 binding capacity increase (Lan et al., 2012; Tejada-Ortigoza, Garcia-Amezquita, Serna-
295 Saldívar, & Welti-Chanes, 2016). Uronic acid was detected in polysaccharides extracted
296 from leaves or seeds of *Psyllium* (Zhang et al., 2019), this acid together with the polar
297 groups and a more surface area to the surrounding water leads to an increase in the
298 swelling volume (Tejada-Ortigoza et al., 2016).

299

300 **3.1.2. Mineral content**

301 Table 3 shows the ash content, total minerals and individual mineral content of both
302 samples (Figs. S1 and S2 original equipment graphs). For both ash and total mineral
303 contents, significant differences were found between PP and PH ($p < 0.05$), where PP
304 had the highest ash and mineral contents, which could be associated because the PP
305 sample came from seed (Table 1). Regarding the individual mineral content, no
306 significant differences ($p > 0.05$) were observed between both DF samples (PP and PH)
307 in Se, Zn and Cu contents. For the other analysed minerals, significant differences ($p <$
308 0.05) were present between the PP and PH DF samples, and the P, K, Ca, Na, Fe and
309 Mn values were higher for PP. The results of Ca, Fe and Cu in *Plantago psyllium* and
310 *Plantago ovata* obtained by Ziemichód, Wójcik and Różyło (2019) were comparable to

311 those presented for the PH sample. In addition, Bukhsh, Malik, and Ahmad (2007)
312 showed similar results in *Psyllium* seed husk to K, Ca and Mn found in the PH sample.
313 Chong et al. (2019) obtained similar values to the PH sample for both ash content and
314 Ca, Mg, and Fe minerals in *Psyllium* husk. However, the Fe value for the PP sample,
315 and also for other trace elements like Mn, Zn and Cu of both samples, should be
316 highlighted because, as Rousseau et al. (2020) pointed out, Fe and Zn deficiency poses
317 global health problems with about 30-33% of the world's population at risk, predominantly
318 in underdeveloped countries.

319

320 **3.1.3. Total phenolic compounds and antioxidant capacity**

321 Table 3 shows the studied samples' TP content and antioxidant capacity (AC). The PP
322 TP and AC values were significantly higher than for the other sample ($p < 0.05$). This
323 was probably due to this sample coming from seed compared to PH, which came from
324 *Psyllium* husk. The TP and AC values obtained for PH were like those presented by
325 Chong et al. (2019) for *Psyllium* husk. However, the TP content for PP was higher than
326 that found by Navarro-González et al. (2011) for tomato peel fibre. According to our
327 results, the TP content of the *Psyllium* samples was positively and significant compared
328 to the studied samples' AC ($p < 0.05$). The Pearson correlation between TP and AC was
329 0.9458. Thus, TP strongly affected AC, which coincides with other authors for Lulo
330 (*Solanum quitoense*) (Igal et al., 2014) and grapefruit (Igal et al., 2019). Given the high
331 TP content of PP, we highlight the remarkable attributes and quality as an alternative
332 source of DF. The TP content presented positive correlations with ash, total mineral
333 content, P, K, Ca, Na, Mg, Fe and Mn (0.9693, 0.9782, 0.9633, 0.9927, 0.9645, 0.9178,
334 0.9260, 0.9347 and 0.9474, respectively) ($p < 0.05$), and also with AC (0.8944, 0.9701,
335 0.9815, 0.9563, 0.9434, 0.9135, 0.9637, 0.9671 and 0.9972, respectively). However, this
336 could be negative as DF and components like polyphenols are related to lower mineral
337 absorption in the small intestine due to binding and/or physical entrapment.
338 Nevertheless, this is believed to be balanced for DF fermentation in the colon by gut

339 microflora as the short-chain fatty acids that form can release trapped minerals to
340 increase the absorptive surface area and their absorption, which is significant in the
341 event of deficiency (Baye, Guyot, & Mouquet-Rivier, 2017).

342

343 **3.1.4. Hydration properties**

344 The hydration properties of DF are related to the chemical structure of component
345 polysaccharides, and other factors porosity, particle size, ionic forms, pH, temperature,
346 ionic strength, type of ions in solution and stresses on fibres (Elleuch et al., 2011). These
347 properties partly determine the fate of DF in the digestive tract and account for some of
348 their physiological effects (Guillon, & Champ, 2000). The definition of WHC is the amount
349 of water retained by a sample without being subjected to stress (Rosell, Santos, & Collar,
350 2009). PH and PP showed significant differences for WHC ($p < 0.05$) (Table 2), and PH
351 had the highest and PP the lowest WHC values. The WHC values of these DF were
352 higher than the values found by Rosell, Santos, and Collar (2009) for all the tested
353 commercial fibres, except for inulin (11.05 g/g), and those observed by Kwindu, Onipe,
354 and Jideani (2018) (3.83 g/g) for *Psyllium* fibre, but were markedly lower than those
355 reported by Chong et al., (2019) (45 g/g) for *Psyllium* husk fibre. As in the results by Zhu
356 et al. (2010) revealed for wheat bran DF before and after grinding, WHC increases with
357 a larger particle size because a reduction in particle size may alter the fibre matrix
358 structure.

359 WRC has DF's ability to retain water when subjected to an external force, such as
360 centrifugation (Ma, & Mu, 2016). Table 2 shows the WRC values of the tested samples
361 and the significant differences appeared between PH and PP ($p < 0.05$). These results
362 were notably lower than those of Kale, Yadav, and Hanah (2016) (45.7 g/g), but were
363 higher than those reported by Kwindu, Onipe, and Jideani (2018) (4 g/g) for *Psyllium*
364 fibre. The WRC of PH was higher than the value of Lan et al. (2012) for the DF isolated
365 from *P. odoratum* by being left to dry in the sun (23.94 g/g), but the PP value was lower
366 than that for cellulose (12.42 g/g). According to de Moraes Crizel et al. (2013) and

367 Grigelmo-Miguel and Martin-Belloso (1999), DF with high WRC values can be used as
368 a functional food ingredient to reduce calories, avoid syneresis and modify both the
369 viscosity and texture of processed food. SWC is the volume occupied by a known fibre
370 weight under the employed condition. In addition, SWC and WRC provide not only an
371 overview of fibre hydration, but also useful information for fibre-supplemented foods
372 (Guillon, & Champ, 2000). The SWC of PH was significantly higher than that of PP ($p <$
373 0.05) (Table 2). Guillon, and Champ (2000) reported a list of fibres' hydration properties
374 with different particle sizes where the range of SWC values was from 5.5 to 11.9 mL/g.
375 Accordingly, the SWC values of both the tested samples fell within this range.

376 The nature of the glycidyl component and the structural characteristics of fibre are
377 involved in the WSI, which is expressed as the percentage of the fraction that is
378 solubilised under defined conditions (de Moraes Crizel et al., 2013). PP had higher
379 solubility, and significant ($p < 0.05$) differences appeared between samples (Table 2).
380 The high solubility of PP could be due to it being a sample with a high soluble fibre (SDF)
381 (data from suppliers in Table 1). It is also well-known that high solubility can inhibit the
382 digestion and absorption of nutrients from the gut (Guillon, & Champ, 2000), such as
383 glucose and cholesterol (Belorio, Marcondes, & Gómez, 2020). Besides, soluble fibres
384 have shown a better ability to provide viscosity and to form gels or act as emulsifiers
385 (Elleuch et al., 2011). The WSI results for PP was higher than those reported by de
386 Moraes Crizel et al. (2013) for DF from orange (28.95%), but lower than shown by
387 Femenia et al. (1997) for DF from cauliflower florets dried at 75 °C (48.1%). However,
388 the WSI value was lower for PH.

389 FAC is fibre's ability to absorb fat or oil, which is important in nutrition for preventing fat
390 loss while cooking because fat is absorbed in the intestinal lumen, which lowers
391 cholesterol (Navarro-González et al., 2011; Ma, & Mu, 2016) and retains food flavours
392 (de Moraes Crizel et al., 2013). Table 2 shows the FAC of the tested samples. The FAC
393 of PH was higher than that of PP, and significant differences were found between
394 samples ($p < 0.05$). The PH value was higher than the values shown for fibre from tomato

395 peel (1.46 g oil/g) by Navarro-González et al. (2011), and was similar to that found by
396 Femenia et al. (1997) for cauliflower stem fibre dried at 40 °C (2.1 g oil/g). However, the
397 PP value was similar for the tomato peel fibre value indicated by Navarro-González et
398 al. (2011).

399 The ability of *Psyllium* to absorb water and oil is by the interaction between the hydroxyl
400 groups of water and those of the polysaccharide macromolecules present in the mucilage
401 (Chaplin, 2003; Dikeman and Fahey, 2006; Beikzadeh et al., 2017). Polysaccharides
402 obtained from seeds and husk of *Psyllium* are comprised of xylose, galactose, rhamnose,
403 arabinose (Patel et al., 2019); then, molecules such as arabinose and xylose create the
404 hydrogen bonds in the mucilage (Beikzadeh et al., 2017). The hydrophilic feature of
405 mucilage causes interaction between water and increases water retention capacity
406 during cooking and storage (Beikzadeh et al., 2017).

407 The physicochemical parameters and hydration properties are related, a correlation
408 analysis between parameters was conducted (Table 4). All the hydration properties
409 showed statistically significant Pearson's correlation coefficients when related to D[4,3],
410 d(0.1), d(0.5), d(0.9), Hg and pH ($p < 0.05$). Hygroscopicity showed positive correlations
411 with hydration properties, except for the WSI, where higher Hg led to a better ability to
412 absorb water and oil. Moreover, a_w and x_w correlated positively with WHC, WRC and
413 FAC, but negative correlations with the WSI, and no correlations with SWC were found.
414 However, pH correlated positively with WHC and the WSI, but negatively with SWC,
415 WRC and FAC. Bulk density (ρ_b) correlated negatively with WHC, WRC and FAC, but
416 positively with the WSI. When ρ_b had high values, the capacity of DF to bind water and
417 oil decreased, but high ρ_b values meant increased DF solubility. However, particle size
418 (D[4,3], d(0.1), d(0.5), d(0.9)) was positively related to hydration properties, except for
419 the WSI. When samples' particle size grew, the absorption capacity of water and oil
420 increased, but samples' solubility decreased. It can be generally stated that a reduced
421 particle size is related to a diminished ability to retain water and oil (Lan, Chen, Chen, &

422 Tian, 2012), but this effect cannot be generalised because both the chemical structure
423 and shape of DF also play an essential role (Rosell, Santos, & Collar, 2009). Besides,
424 authors like Zhu et al. (2010), Lan et al. (2012), and Ma, and Mu (2016) supported this
425 correlation by reporting similar results. Conversely, other authors like Chantaro et al.
426 (2008) and Rosell et al. (2009) showed that for a smaller particle size, fibres were better
427 able to bind water. These authors also showed the importance of not generalising and
428 analysing each fibre type because, as Tejada-Ortigoza et al. (2016) stated, these
429 properties are related to environmental conditions, the chemical structure of the DF
430 polysaccharides, and to treatments and/or extraction conditions.

431 Moreover, a correlation analysis between the multimineral content and hydration
432 properties was performed (Table 4). The total mineral content showed statistically
433 significant negative Pearson's correlation coefficients when related to all the hydration
434 properties (SWC, WHC, WRC and FAC), except for the WSI, which had a positive
435 correlation ($p < 0.05$). Additionally, minerals P, K, Ca, Na, Mg, Fe and Mn correlated
436 negatively with WHC, WRC and FAC, but positively with the WSI. This situation could be
437 related to the valence and ratio of the adsorbed ions, because the ion valence increased
438 or the ratio decreased, and the hydration force magnitude increased (Li et al., 2020). For
439 this reason, these minerals must be divalent ions because they are adsorbed in
440 completely hydrated states (Li et al., 2020). However, SWC was negatively associated
441 with K and Ca.

442

443 **3.2. Gel analysis**

444 **3.2.1. Physicochemical and optical properties**

445 Solutions of both DF samples were prepared at the 1, 2, 3, 4, 5, 6, and 7% concentrations
446 (heated and unheated) to know the physicochemical and mechanical properties of each
447 concentration, and their possible different uses in food. Table 5 shows both samples' x_w ,
448 pH and solution colour at each concentration. The x_w of both samples lowered when the
449 DF concentration rose in both (with and without heat treatment). An interaction occurred

450 between samples' concentration and the employed DF sample (PP or PH) when x_w
451 lowered as the concentration of both DF samples increased. With PP, the drop in the 6%
452 and 7% concentrations was significantly more marked ($p < 0.05$) regardless of the
453 temperature at which structures formed.

454 The pH of the tested gels was similar for both samples, and the pH went from 6 to 7.
455 However, significant differences were observed in the pH values of both samples with
456 and without heat treatment ($p < 0.05$) (Table 5). An interaction between concentration
457 and used DF sample (PP or PH) was observed, and the pH values slight dropped for
458 both DF samples when concentration rose ($p < 0.05$). For pH, the most marked decrease
459 was observed in the PH sample up to the 3% fibre concentration (with and without heat
460 treatment). The sample with the highest pH was 65PH at the 1% concentration. No
461 significant effect on the pH values was observed in the solution concentrations for the
462 PH fibre because of heat treatment ($p > 0.05$), whereas the solutions made with the PP
463 fibre had slightly lower pH values in the heated samples ($p < 0.05$).

464 With both samples, when the DF samples' concentration went below 4%, the solid
465 content precipitated. When the concentration rose, dispersion homogeneity markedly
466 increased because samples were mixtures of whole cells and dispersed cell wall
467 materials of different particle sizes, as shown in Fig. 2. Therefore, the bigger material
468 absorbed water until it formed a stabler gel structure. Table 5 depicts the colorimetric
469 parameters (L^* , a^* and b^*) of the formulated samples. To illustrate the colour samples,
470 the images of gels are presented in Fig. 3 (with and without heat treatment). It can be
471 seen that, although both samples came from *Psyllium*, gel colours significantly differed
472 ($p < 0.05$), which could be due to the fact that PP came from *Plantago ovata* seed and
473 PH came mostly from husk (Table 1). Similar behaviour was observed in the gels made
474 with both samples, and parameters L^* , a^* and b^* significantly increased with a rising fibre
475 concentration both with and without heat treatment ($p < 0.05$). As observed in this study,
476 Wang et al. (2018) reported that the colour parameters increased in the homogenised
477 suspension and became more saturated with red and yellow. The colour of gel samples

478 depended mainly on the colour of solids as seen in Fig. 1, where PP was markedly
479 darker. The increase observed in the colour parameters was also related to the used DF,
480 and the PP gels generally had higher L^* and a^* values in the unheated and heated
481 samples ($p < 0.05$), but lower b^* values. Moreover, no significant differences were
482 observed in either luminosity (L^*) or redness (a^*) for the DF sample (PP or PH) and the
483 applied treatment ($p > 0.05$). Both samples displayed the same behaviour, but
484 yellowness (b^*) significantly decreased, which was observed when samples were
485 prepared with heat treatment in the gels formulated with PP ($p < 0.05$). The colour of
486 these samples was darker than the gels made with hydrocolloids like xanthan gum
487 (Chong et al., 2019). Other authors have indicated that the incorporating *Psyllium* into
488 different food products can increase colour darkness in products (Ahmadi, Kalbasi-
489 Ashtari, Oromiehie, Yarmand, & Jahandideh, 2012; Figueroa, & Genovese, 2019). Gel
490 colour is related to mineral content because positive Pearson correlations were found.
491 The increase in the luminosity (L^*) of both samples (heated and unheated) can be
492 associated with a higher total mineral content (0.8699), and Ca and Na showed a higher
493 correlation (0.8898 and 0.8877, respectively). However, an increase in redness (a^*) was
494 more related to the total mineral content when samples were heated (0.8507.; Na, Ca,
495 Mg, K, P and Fe were the minerals that were the most related to a rise in a^* when gels
496 were formed with heat (0.8233, 0.8218, 0.8128, 0.8115, 0.8062 and 0.8022,
497 respectively). For yellowness (b^*), a higher and positive correlation was also found with
498 the total mineral content when gels formed without heat treatment (0.8463). In this case,
499 K, P, Fe, Mg and Mn were the minerals that most strongly influenced the increase in b^*
500 (0.8976, 0.8923, 0.8874, 0.8801 and 0.8559, respectively).

501

502 **3.2.2. Mechanical properties**

503 The back extrusion assay was performed at all the gel concentrations (1-7%), similarly
504 to a previous study in order to know the mechanical properties of both *Psyllium* DFs (Fig.
505 S3 original graphs). Table 6 depicts the back extrusion parameter results. This table

506 indicates that not only the consistency and firmness of *Psyllium* gels increased as the
507 DF concentration rose, but so did viscosity and cohesiveness as results showed by
508 Noguero, Igual and Pagán-Moreno (2021) for different DFs. However, the results of this
509 study showed that both *Psyllium* fibres had greater values of all back extrusion
510 parameters than DFs showed by Noguero, Igual and Pagán-Moreno (2021). Moreover,
511 a significant interaction took place between concentration and temperature ($p < 0.05$),
512 and all the back extrusion parameters increased when the gels were heated. This
513 increase in consistency was similar in the gels with both the *Psyllium* DF samples. The
514 gelling process begins with the formation of junction zones, these junctions grow and
515 join the polysaccharide molecules to form the gel network (Yu, Perret, Parker, & Allen,
516 2003). However, the interaction between treatment and the employed DF sample was
517 observed for firmness, cohesiveness and viscosity where the gels formulated with the
518 PP sample obtained significantly higher results for these parameters from the 5%
519 concentration ($p < 0.05$), except for viscosity, which presented significant differences
520 only in the 7% concentration. It is a well-known fact that *Psyllium* fibre has positive gelling
521 properties (Yu et al., 2003) and Askari et al. (2018) indicated that the gels formulated
522 with *Psyllium*-maize starch films had a more compact and homogeneous structure than
523 the films made only with starch. Therefore as this study indicates, both *Psyllium* fibres
524 can be used as gelling agents in food products with or without starch addition. In line with
525 the result shown in this study, Ren et al. (2020b) indicated that hydrated whole *Psyllium*
526 husk powder exhibited a gel-like property and this gel became stronger when it was
527 formed by applying heating. Authors like Igual et al 2013 and Igual et al., 2014 indicated
528 that some parameters like consistency and viscosity are very important because they
529 are related to coverage in mouth with gelled products.

530 The Pearson correlations indicated that all the back extrusion parameters (consistency,
531 firmness, viscosity, cohesiveness) were associated with samples' x_w , pH, and mineral
532 composition. A negative correlation between x_w and pH with consistency (-0.8044 and -
533 0.7445, respectively) and firmness (-0.7777 and -0.7141) was found, and a positive

534 correlation appeared between x_w and pH with viscosity (0.9035 and 0.8081, respectively)
535 and cohesiveness (0.8923 and 0.7992, respectively). The total mineral content was
536 positively related to consistency and firmness (0.7494 and 0.7636, respectively), and Ca
537 (0.8267 for consistency and 0.8176 for firmness) and Na (0.8247 for consistency and
538 0.8154 for firmness) were the most influential minerals. However, viscosity and
539 cohesivity negatively correlated with total mineral content (-0.8149 and -0.8609,
540 respectively). In this case, Ca (-0.8939 for viscosity and -0.9213 for cohesiveness) and
541 Na (-0.8859 for viscosity and -0.9223 for cohesiveness) were the most influential
542 minerals. In practice, Li et al. (2018) and Liu et al. (2018) indicated that the gelation of
543 food biopolymers could be induced by different approaches, including temperature,
544 pressure, acids, salts, enzymes, ethanol, among others. From the results of this study,
545 the consistency and firmness of the *Psyllium* gels increased with a lower pH. It can also
546 be stated that gel formation is due to ionic interactions with Ca and Na (Mao et al., 2020).
547 The consistency, firmness and viscosity parameters of the gels formed at cold
548 temperature (5 °C) were also associated with DF samples' SWC, and negatively with
549 firmness and consistency (-0.8740 and -0.8698, respectively) and positively with
550 viscosity (0.8886). However, consistency was positively related to the WSI (0.8143).
551 When gels were formed with heating, a negative Pearson correlation with WHC was
552 found (-0.8187).

553 As the 1%, 2% and 3% concentrations were not homogeneous and did not form a stable
554 hydrogel, a decision was made to perform flow curves and TPA from only concentrations
555 4% to 7%. Hence the samples with a consistency lower than 100 N s as a result of the
556 back extrusion assay were characterised by the flow curve analysis (Fig. S4 original
557 graphs). Consistency (k), flow behaviour (n) and goodness of fit (R^2) are shown in Table
558 7. All the data were fitted with Ostwald's power law. The PP gels had the highest k and
559 an increase in k was related to a rising DF concentration, Su, Zhu, Adhikari, Li, and Wang
560 (2020) indicated the same results for the citrus fibre-oil dispersions. On the contrary, no
561 significant differences were observed between the gels made with PH fibre ($p > 0.05$).

562 All the formulated gels had a k higher than 20 Pa s. So their gelling properties can be
563 identified with semisolid or spoonable foods (Aguayo-Mendoza et al., 2019), and can be
564 used as fat replacers and/or texture modifiers of meat analogues, among others. n was
565 lower than 1 in all the samples, which means that our samples behaved as pseudoplastic
566 fluids. As no changes were observed in n due to increasing PH fibre content ($p > 0.05$),
567 the rising PP concentration led to a significant decrease in this parameter ($p < 0.05$).
568 Both k and n were related to particle size (D[4,3] and d (0.9)). For k , a negative Pearson
569 correlation was presented, which meant that a drop in k was associated with a bigger
570 particle size (-0.9211 for D[4,3] and -0.9757 for d (0.9)). However, positive correlations
571 were found between D[4,3] and d (0.9) with n (0.8822 and 0.9545, respectively). Wang
572 et al. (2018) have also reported that this parameter depends on particle size distribution.
573 Pearson correlations were found between the flow curve parameters and hydration
574 properties, except for SWC. k and η_{ap} were negatively related to WHC (-0.9427 and -
575 0.8861, respectively), WRC (-0.9939 and -0.8766, respectively) and FAC (-0.9933 and -
576 0.8394, respectively), but positively with the WSI (0.9914 and 0.8123, respectively). n
577 was positively correlated with WRC and FAC, and negatively with the WSI (0.8862,
578 0.9111 and -0.9252, respectively).
579 Dikeman and Fahey (2006) (p. 652) indicated that “*viscosity as related to DF refers to*
580 *the ability of some polysaccharides to thicken or form gels when mixed with fluids*
581 *resulting from physical entanglements among the polysaccharides constituents within*
582 *the fluid or solution*” and apparent viscosity is the most common term in the literature
583 related to DF. The trend of samples’ apparent viscosity is shown in Fig. 4, where it can
584 be observed that the tendency of all the gels was similar, although the PH samples
585 seemed to have lower apparent viscosity. Table 7 confirms this. It shows the samples’
586 η_{ap} and that no concentration dependences were found with either sample ($p > 0.05$), but
587 both the η_{ap} of the PP gels was significantly higher than it was for the PH gels ($p < 0.05$).
588 These results agree with the reports by Agarwal, Hewson, and Foster (2018), and shear
589 viscosity was related to fibres’ source, processing and microstructure. Therefore in line

590 with Ren et al. (2020b), freshly prepared *Psyllium* husk dispersion can be described as
591 the concentrated suspension of gel particles and its rheological properties can be
592 ascribed to particles' viscoelastic properties and to the physical contacts and friction
593 between them. It is noteworthy that authors like Niknam, Ghanbarzadeh, Ayaseh, and
594 Rezagholi (2018) have reported that the addition of *Plantago major* seed to emulsions
595 can enhance the stability of samples during storage by increasing continuous phase
596 viscosity. Therefore, this could also be achieved by adding PP and/or PH. The present
597 study confirms both fibres can be used as texturizing agents to modify the food texture
598 to pudding-like consistency (> 1750 mPa s) for patients with oropharyngeal dysphagia
599 (Ribes, Estarriaga, Grau, Talens, 2021).

600 When characterisation ended, a TPA was performed in those samples that presented a
601 higher back extrusion consistency than 100 N s (Fig. S5 original graphs). The TPA
602 parameter results are shown in Table 8. Regarding the hardness results for the gels
603 formed without heat, it can be seen that the different concentrations of each DF sample
604 ($p > 0.05$), but the hardness of the gels formulated with PP was significantly higher ($p <$
605 0.05). When gels were formed by heating, concentration fibre dependence was found for
606 both samples, as was a high DF concentration and marked hardness. This increased
607 hardness was greater for the PH gels than for PP one. The highest results were for the
608 65PH sample at 7% ($p < 0.05$). A heat treatment effect appeared for the PH sample, and
609 the hardness of the gels formed by heating with the DF sample was higher, high
610 temperature fractions have stronger gel properties (Ren et al., 2020b). Comparing these
611 results with gels formed with other vegetable fibres (Noguerol, Igual, Pagán-Moreno,
612 2021), *Psyllium* gels form more stable and firmer gels

613 All the results for adhesiveness were negatives, which indicated that it formed a sticky
614 gel. The PH samples with no heat treatment presented lower adhesiveness than the gels
615 formed at 65 °C, but the adhesiveness for the PP gels decreased when gels were formed
616 with heating. It could be related to the different composition of the *Psyllium* fibre, because
617 the PP fibre is from the seed and has more proteins and carbohydrates (Table 1) which

618 can modify its conformation with heating. In addition, Ren et al. (2020b) indicated that
619 during heating, the gel phase gradually expanded and disappeared, which might play
620 the role of junction zone formation and responsible for the thermoreversible gel-like
621 properties. An interaction was observed between adhesiveness and the increased DF
622 concentration with both samples. The importance of this parameter lies in food texture
623 becoming unpleasant for consumers when it adheres to the palate and requires much
624 effort to separate it. It can be noted that springiness was similar for all the samples and
625 did not depend on the used fibre or concentration. Although, formulations with high
626 adhesiveness caused prolonged retention in buccal cavity (Bhatia & Ahuja, 2013).
627 Regarding cohesiveness, the gel samples with heat treatment generally obtained
628 significantly higher results ($p < 0.05$). It also depended on the DF used because the
629 cohesiveness of PP was greater ($p < 0.05$) at the highest concentration tested in this
630 study.

631 The chewability of both *Psyllium* samples was higher than the gel formed with a
632 combination of bamboo, psyllium and citric fibre presented by Noguerol, Igual and
633 Pagán-Moreno (2021). The highest chewability value was for the 65PH 7% gel. This
634 parameter also depended on fibre concentration for the gels formed at 65 °C. Authors
635 like Fradinho, Soares, Niccolai, Sousa, and Raymundo (2020) have indicated that both
636 hardness and adhesiveness are dependent on the *Psyllium* concentration in pasta, and
637 that pasta with *Psyllium* is less adhesive due to this material's gelling properties, which
638 favour a more cohesive structure with less cooking loss. As in the back extrusion assay,
639 positive correlations were found between hardness and Ca and Na minerals (0.6720 and
640 0.6607, respectively), but a negative correlation was observed when adhesiveness was
641 related to these minerals (-0.7258 and -0.7143, respectively). With the cohesiveness
642 Pearson correlations, this was associated with minerals K and Mn (0.6078 and 0.6056,
643 respectively) but, as with hardness, chewability showed a relation with Ca and Na
644 (0.6893 and 0.6789, respectively). As a result, both fibres PP and PH displayed gelling
645 properties at not only lower temperatures (65 °C), but also at cool temperatures (5 °C).

646 This should be highlighted because these samples can be used to adapt the texture of
647 different foods, while supplementation with *Psyllium* fibres implies potential health
648 benefits (Jalanka et al., 2019; Jane, McKay, & Pal, 2019). As with back extrusion and
649 flow curves, the TPA parameters were also related to the hydration properties of the DF
650 samples. When samples were formed without heat treatment, hardness correlated
651 negatively with WHC, WRC and FAC (-0.8564, -0.9114 and -0.9069, respectively), and
652 positively with the WSI (0.9247). On the contrary, adhesiveness was positively related to
653 WHC, WRC and FAC (0.9443, 0.9150 and 0.9101, respectively) and negatively to the
654 WSI (-0.8839). The resilience and chewability of the cold gels were associated with all
655 the hydration properties: negatively with WHC, WRC, SWC and FAC and positively with
656 the WSI (respectively -0.8996, -0.8917, -0.9415, -0.9034 and 0.9534 for resilience; -
657 0.9015, -0.9521, -0.7637, -0.9518 and 0.9673 for chewability). However, when gels were
658 formed with heating, relations were noted only between the cohesiveness and hydration
659 properties, with negative correlations with WHC, WRC and FAC (-0.9099, -0.9758 and -
660 0.9714, respectively), and a positive correlation with the WSI (0.9671). Therefore, gel
661 structure formation (heating or not) depended on the hydration properties of the DF
662 samples.

663

664 **3.3. Practical implications of this study**

665 The clean label trend has emerged due to the concern of consumers about healthiness
666 and sustainability of food products (Euromonitor International, 2016). Moreover, the
667 COVID-19 health crisis has increased the concern for a healthy lifestyle (Academia
668 Española de Nutrición y Dietética, 2020). Thus, the importance to include DF in our diet,
669 since it offers health benefits for body weight control, cholesterol, diabetes, constipation,
670 diarrhoea, inflammatory bowel disease, irritable bowel syndrome symptoms, and colon
671 cancer prevention (Ma, & Mu, 2016; Franco et al., 2020; Belorio, Marcondes, & Gómez,
672 2020).

673 For these reasons, according to the results obtained in this study, these two *Psyllium*
674 fibres could be used as new clean label texturizers, as well as to avoid the negative
675 effects in foods such as cooking loss, drip loss, syneresis, and fat loss. In addition, they
676 could also be used as fat replacers or to develop new plant-based products, since one
677 of the main problems for their development is texture. Furthermore, one of the main
678 reasons for the lower consumption of plant-based products by omnivores is because
679 they do not like the texture and flavour (Fiestas-Flores & Pyhälä, 2018; Nogueroles, Pagán,
680 García-Segovia & Varela, 2021). This DF could also be used to adapt food products to
681 patients with oropharyngeal dysphagia, because one of the most employed strategies to
682 overcome this problem is the use of texturing agents that modifies foods texture (Ribes
683 et al., 2021).

684

685 **4. CONCLUSIONS**

686 This study revealed that PH had the highest values for hydration properties, thus could
687 be a functional ingredient to avoid physical food properties, such as syneresis and fat
688 loss during cooking, and to improve textural and sensory characteristics. However, the
689 AC, the TP and the mineral content for PP were higher, which is a highlighted finding in
690 quality terms as an alternative source of DF. As a result of the rheological and textural
691 analysis, both fibres showed good gelling properties from concentration 4% to 7% at both
692 high (65 °C) and cool (5 °C) temperatures. These properties generally depended on the
693 DF concentration. According to these results, both PH and PP could lead to different gel
694 types that would allow their use as new sources of DF in food with different
695 characteristics, a use that could promote health benefits for human health. In addition,
696 they could also be used as fat replacers, to develop new products, to modified textures
697 and to adapt food products to elderly people. However, further studies in different foods
698 are required to check behaviour with other ingredients and to adjust the suitable
699 concentration to each food type.

Mean values (and standard deviations).

For the samples under the same conditions, the letter in superscript in the column indicates the homogeneous groups established by the ANOVA ($p < 0.05$) (^{a-r} for unheated, and ^{z-r} heated samples). To compare the same sample to the temperature effect, the same capital letter in superscript in the column indicates the homogeneous groups established by the ANOVA ($p < 0.05$). C: Concentration (%); 65 indicates the samples heated at 65 °C, 20 min; PH: Plantago Husk; PP: Plantago Powder.

Table 7. Flow curve parameters k (consistency index), n (flow index) and η_{ap} (shear viscosity at 50 s^{-1} shear stress) of the formulated *Psyllium* gels.

Ostwald-de Waele model					
Samples	C (%)	k (Pa s ⁿ)	n	η_{ap} (Pa s)	R^2
PH	4	21.5 (0.3) ^c	0.468 (0.006) ^a	2.7 (0.04) ^b	0.99
	5	24 (3) ^c	0.464 (0.016) ^a	3.0 (0.2) ^b	0.99
PP	4	42 (2) ^b	0.404 (0.007) ^b	4.10 (0.09) ^a	0.99
	5	69.4 (0.5) ^a	0.32 (0.05) ^c	4.91 (1.02) ^a	0.99

Mean values (and standard deviations).

The same letter in superscript in the line indicates the homogeneous groups established by the ANOVA ($p < 0.05$). C: concentration (%); PH: Plantago Husk; PP: Plantago Powder.
