## 24 25 26 27 Abstract

28  
29 Virtual reality is becoming an opportunity for multidisciplinary collaboration, including  
30 sensory science. The main objective of this work was to compare visual expectations  
31 generated by five real cakes evaluated in a laboratory testing booth with their virtual  
32 versions in a virtualized sensory booth. Real cakes were designed following the current  
33 pastries trends, and virtualization was made using a photogrammetric process. The  
34 virtual sensory booth was designed using Unity3D software. The participants were  
35 immersed in the 3D virtual environment through a head-mounted display (HMD). Data  
36 were analyzed using ANOVA mixed model, internal preference mapping and cluster  
37 analysis. The effects of context (real and virtual), the order in test session (crossover  
38 design), and socio-demographic factors were studied. **The results showed no statistically  
39 significant differences within real and virtual studied cakes. These results create new  
40 perspectives of the potential of this methodology to be used to rate virtual foods in an  
41 immersive environment at the same level as real foods. Regarding the impact of the  
42 socio-demographic factors on the acceptance of the cakes, only the effects of gender  
43 and sweet-tooth were statistically significant. Males assessed all variables associated  
44 with the cakes significantly higher ( $p<0.05$ ) than females. In the same way, all variables  
45 in all cakes were better evaluated by participants with a self-declared sweet-tooth  
46 ( $p<0.05$ ). In the internal preference map, participants were segmented into three clusters  
47 that could be identified with the different trends in the pastries market. These results may  
48 help companies build tailor-made marketing strategies using Immersive technologies to  
49 evaluate new food products to satisfy different consumer segments.**

## 44 1. Introduction

45 In the last decades, the most creative chefs around the world have been using scientific  
46 knowledge to innovate in their restaurants, therefore enhancing demands for innovation  
47 in complementary gastronomy areas such as bakery, pastries, food delivery, and  
48 beverages (Albors-Garrigos et al., 2013; Martínez-Monzó et al., 2013). **Traditional pastry  
49 based on empirical and intuitive experience has progressively transformed into a creative  
50 profession with rigorous knowledge of food ingredients and strong technical skills.** This  
51 high-quality Fine Pastry, while demanding in technique, has a whole aesthetic and  
52 emotional sensitivity in an amalgam of flavours, colours, textures and shapes of different  
53 ingredients (Rodes & Hernandez, 2011).

54 Fine Pastry is one of the most popular and increasing food categories to innovate in, due  
55 to its global consumption and sales as well as product range. Changes or modifications  
56 to the composition of these new creations can have an impact on the organoleptic  
57 characteristics of the final product, however, it is essential to ensure that consumer  
58 acceptance is maintained (Birch & Bonwick, 2019).

59 Market studies introduce the following key bakery and pastry trends for the next years:  
60 “Indulgence”, “Fusion”, “Identity”, and “Eatertainment” (Fona International, 2019).  
61 “Indulgence” refers to guilt-free enjoyment, where chocolate remains the most desired  
62 ingredient, and with over 80% of consumers considering that a balanced diet can include  
63 some indulgence. “Eatertainment” searches for new and different experiences, with new  
64 and exciting ingredients, sophisticated designs, and attractive appearances to be shared  
65 on social media. “Fusion” places its emphasis on global-inspired flavours, inspired in  
66 sweet-and-salty caramel sauces with unexpected creative textures. And finally, the  
67 “Tradition” trend, which aims to vindicate the identity and culture in each region (Fona  
68 International, 2019).

69  
70 In the marketplace, people do not have the ability to taste food prior to purchase.  
71 Therefore, the consumer creates a series of expectations based on both intrinsic and  
72 extrinsic product cues. Intrinsic cues are associated to the product’s sensory aspects  
73 (appearance, size or visual structure, texture, or flavour) and are one of the major food  
74 choice determinants (Cunha et al., 2018). On the other hand, extrinsic characteristics  
75 such as logo, packaging, brand, claims or even retail context, contribute to generate  
76 these expectations (Kpossa & Lick, 2020), where the evaluation of this plethora of cues  
77 by the consumers combines physiological, emotional and cognitive responses, which  
78 play a fundamental, often unconscious, role in consumer decisions (van der Laan et al.,  
79 2011).

80  
81 Since 2014, multisensory experiences (including visual, olfactive, auditive and tactile  
82 stimuli) have been designed to provide gastronomic dining experiences (Crofton et al.,  
83 2019; Youssef & Spence, 2021). **The arrival of Covid-19 has accelerated many of the  
84 trends that were already in place before the pandemic, especially those that allowed the  
85 reduction or elimination of contact between people. The scenario has changed  
86 completely, and the virtual is replacing the physical everywhere: medical centres,  
87 hospitals, offices and small businesses, meeting places and entertainment, among  
88 others, as well as in teaching and science (Barnes, 2020). In this digital context, virtual  
89 reality offers emerging opportunities for the discipline of sensory science (see review  
90 Crofton, 2019). In his review, Crofton shows that virtual reality can be applied in the form  
91 of context-enhancing technologies by replacing real environments with immersive  
92 settings, improving the ecological validity of research, and allowing for a better prediction**

93 of consumer sensory evaluations. This can be an opportunity to promote safety and  
94 create memorable experiences, in turn helping the gastronomy sector to redefine its  
95 future (Garibaldi & Pozzi, 2020; Schiopu et al., 2021). In this frame, there are two key  
96 points that must be considered when translating from the real to the virtual world, or vice-  
97 versa: the characteristics of the product itself (Köster, 2009) and the traits of the specific  
98 context in which the tasting takes place (Bangcuyo et al., 2015; Dacremont & Sester,  
99 2019; Jaeger & Porcherot, 2017; Kim et al., 2015; King et al., 2007) -the latter being the  
100 more increasingly explored.

101 A consumer test in the absence of a context may imply a "situational fallacy", leading to  
102 less involvement and consequently to an irregular and invalid hedonic classification  
103 (Köster, 2003). The same food product served in a different context (sensory booths,  
104 restaurant, home, etc) is perceived with different hedonic quality (Boutrolle et al., 2007;  
105 García-Segovia et al., 2015; King et al., 2007). Virtual Reality (VR) is becoming a great  
106 opportunity for multidisciplinary collaboration. The use of VR is emerging as an  
107 alternative to physically created immersion environments. With this technology,  
108 consumers wear VR helmets/glasses to experience a complete visual and audio  
109 environment (Porcherot et al., 2018; Siegrist et al., 2019). There are increasing  
110 possibilities to simulate real situations on a computer and promote users' immersion and  
111 sensations in different environments (Bangcuyo et al., 2015; Kong et al., 2020; Netto &  
112 Oliveira, 2004; Picket & Dando, 2019; Schnack et al., 2019; van Bergen et al., 2021;  
113 Wang et al., 2020). Virtual environments are designed to provoke high user involvement  
114 and provide extrinsic contextual information, presenting enormous potential as an ideal  
115 alternative to traditional environments used in sensory analysis (Hathaway & Simons,  
116 2017). Recreation of usual food consumption scenarios through immersive  
117 methodologies, such as VR, has been increasingly used by different researchers.  
118 Sinesio et al. (2019) compared the acceptance and emotional responses in consumption  
119 of different types of beers, in a virtual pub, a real pub, and a traditional central location  
120 test. Torrico et al. (2020) evaluated and compared perception, sensory acceptability, and  
121 emotional responses of a Cabernet Sauvignon wine in traditional sensory booths,  
122 contextual environments, and VR simulations. Stelick et al. (2018) developed a study  
123 where consumers were invited to taste three identical samples of blue cheese in three  
124 different contexts, a sensory booth, a virtual garden bench, and a virtual cow stable.

125 The choice of a food product is a complex process that depends on different interrelated  
126 variables. Changes to food texture during eating have an intense influence on food  
127 choice and acceptance of new products (Crofton et al., 2019). However, consumer  
128 perceptions or choices could be very sensitive to the visual realism of the food image  
129 depicted (Crofton et al., 2019). Appearance provided by the sense of vision is a more  
130 effective means of foraging, predicting which foods are likely going to be safe and  
131 nutritious to consume, and generating those expectations that will constrain the  
132 consumption experience (Spence et al., 2016; Stierand, 2016). At the moment, only  
133 Gouton et al. (2021) has compared VR with a real environment. In this work authors used  
134 a set of chocolate cookies to validate visual attribute perception assessed in real  
135 conditions (real cookies in natural environment) and VR (virtual cookies presented in VR  
136 in the same context). All results suggest that this technology is promising to provide a  
137 frame for further applications, such as the possibility of personalized design food  
138 products based on consumer expectations, desires, or preferences, offering food  
139 companies, retailers, restaurants or small businesses a new opportunity to digitalize and  
140 innovate (Wang et al., 2021).

141 For both context and food product, it is essential to ensure a realistic quality of the visual  
142 simulation due to consumer perceptions, as choices are very sensitive to the visual  
143 realism depicted (Crofton et al., 2019; Gouton et al., 2021; Ledoux et al., 2013).  
144 Currently, one of the most representative virtualization software on the market is the 3DS  
145 MAX software, its interface being simple and clear, and having a powerful modelling  
146 function, widely applied in the creative design industry (Peng et al., 2011).

147 Based on the opportunity that VR offers to sensory science, the main objective of this  
148 work was to compare participants' visual expectations in real and virtual environments  
149 using the same context (testing booth) and the same five designed cakes. **The impact of  
150 age, gender, eating behaviour, nutritional knowledge and socioeconomic variables on  
151 visual expectations was also studied as a secondary objective.**

152 **The overarching goals of this work are to evaluate if the mere immersion in a virtual  
153 environment would have any impact on the evaluation of food product expectations, and  
154 if a virtual sensory booth would allow relevant immersion, keeping the same  
155 discriminating power as a real life laboratory booth, thus opening new avenues for the  
156 set-up of sensory testing under COVID-19 or any other situation of restricted access to  
157 a sensory lab.**

## 158 2. Material and methods

### 159 2.1 Participants recruiting

160 One hundred and ten participants were recruited from *Universitat Politècnica de*  
161 *València's* participant database. The participants were recruited using a convenient  
162 intentional and reasoned sampling with predetermined inclusion criteria: a) at least  
163 occasional consumption of special cakes, b) **self-reported** intermediate interest in  
164 technology, c) free from allergies or diabetes disease. This non-probabilistic method is  
165 used more often than any other sampling in behavioural science to reach a first approach  
166 of results related to a research subject (Carrillo, 2012; Graveter & Forzano, 2008;  
167 Guerrero et al., 2010). In the recruitment phase, no information was provided about the  
168 objective of the project. The **Institutional Review Board** was informed, and this study was  
169 reviewed and approved. All subjects gave their informed consent before engagement in  
170 the study. For data security purposes, all subjects were assigned a random three-digit  
171 code. Data was treated anonymously and following the European General Data  
172 Protection Regulation (Regulation E. C., 2016).

### 173 2.2 Environment design: real versus virtual sensory booth

174 In the Real environment, the sensory booth of the Polytechnic Innovation City (at  
175 *Universitat Politècnica de Valencia*) was used (Figure 1a). The visual evaluations were  
176 carried out individually in sensory booths, without contextual tracks, under white lighting.  
177 The ambient temperature ( $22 \pm 2$  °C) and air circulation were controlled during the  
178 sessions (ISO, 2014).

179 In the Virtual environment, a duplicate sensory booth (Figure 1b) was created by taking  
180 photographs with a 360-degree **panoramic view** combined with 3D elements in the  
181 background, using the 3DMax software (Autodesk, Mill Valley, CA). This resulted in a  
182 realistic environment and faithful reproduction of the sensory booths used in the real  
183 context, designed using the Unity3D software (Unity Technology, Copenhagen, DK). The  
184 participants were immersed in the 3D virtual environment through a head-mounted  
185 display (HMD) Oculus Rift S (Lenovo, Hong Kong, China), in which the virtual

186 environment was presented. This device allowed subjects to move and turn their heads  
187 in the virtual world in a very natural and realistic way (Figure 1c).

188 \*\*Figure 1

### 189 2.3 Stimulus

190 In line with current trends, five cakes with different characteristics designed by “Casa La  
191 Curra” (Torrent, Valencia, Spain) were used in this study (Figure 2). Following the  
192 “Indulgence” trend, a “Coulan” (C) cake with molten chocolate heart of Guanaja 70% and  
193 raspberries (Figure 2a) was created. Considering the “Eatertainment” trend, the “Leonor  
194 cake” (LC) and “Saffron cake” (SC) were designed. LC was made of a *dacquoise* of  
195 coconut and almonds at the base, filled with a creamy almond praline and 34% Ivorie  
196 lemon mousse with white chocolate and decorated on the surface with pieces of candied  
197 orange (Figure 2b). SC consisted of a base of butter biscuit filled with a saffron cream  
198 with granny smith apple, steamed with saffron, rosemary honey and mousse of Manjari  
199 chocolate 64% (Figure 2c). “Walnut cake” (WC) represented the “Fusion” trend, being  
200 made of a *sablee breton* consisting of salted caramel cream, nuts, and creamy milk  
201 chocolate (Figure 2d). Finally, the “Chocomuffin” (CM) is a conventional muffin  
202 incorporated with a filling of 70% Guanaja chocolate (Figure 2e) representing the  
203 “Tradition” trend. The cakes were all frozen and taken out of the freezer 30 minutes prior  
204 to testing.

205 \*\*Figure 2

206 All the pastries were also virtualized using a photogrammetric process (Figure 2a-e). **In  
207 this study, 3DS Max was used to create a premium realistic context. To obtain the most  
208 realistic render of our fine cakes, the real products were virtualized using a  
209 photogrammetric and 3D scanning process.** The photogrammetric process consisted in  
210 collecting 80 pictures of the cakes in a hemispherical space by mean of the Orbitvu  
211 ALPHASHOT XL V2 3D scanner (Orbitvu, London, UK). These photographs were later  
212 used to obtain an accurate and highly photorealistic 3D model of each cake, using the  
213 RealityCapture software (Capturing Reality, Bratislava, SK) and the reconstructions were  
214 exported to .fbx format supported by Unity 2017.2.0f3<sup>®</sup> software.

215 The samples were presented in a randomized order between participants, while  
216 remaining the same across testing environments for each participant, to avoid changes  
217 in hedonic scores due to order effects (Mead & Gay, 1995) and to help ensure that the  
218 main variable influencing the data was the environmental difference.

### 219 2.4. Design and procedure

220 A crossover experimental design was selected. In this experimental design, participants  
221 were divided into two groups and different contexts (Real and Virtual) were evaluated  
222 during two time periods. **After three weeks, the participants crossed over from one  
223 context to another. Between time periods, a washout time was aimed to minimize the  
224 probability of participants memorizing the answers (carry over effect).** This design yielded  
225 a more efficient context comparison, as fewer participants were required to attain the  
226 same level of statistical power or precision as other statistical designs. Each group was  
227 balanced with respect to their **age group** ( $\chi^2_2=3.727$ ,  $p = 0.155$ ) and gender ( $\chi^2_1=3.456$ ,  
228  $p = 0.063$ ).

229 The experimental procedure was properly explained to all participants before the test  
230 started and each session lasted approximately 15 minutes. The sessions took place  
231 between 10:30h and 12:00h in the morning and between 18:00h and 19:30h in the

232 afternoon. Initially, participants rated their appetite by evaluating hunger on a 7-point  
233 Likert scale, in which the anchors ranged from 1 ("Not hungry") to 7 ("Very hungry"). The  
234 five cakes were presented monadically in a blind condition (labelled with random three-  
235 digit codes) following a complete balanced design. The virtual context was visualized by  
236 means of a head mounted display (HMD), model Oculus Rift S (Oculus Rifts S, Lenovo).  
237 The participants used a 7-point anchored scale to evaluate visual expectations about  
238 appearance (1-Extremely unacceptable to 7-Extremely acceptable), serving size (1-  
239 Extremely inadequate to 7- Extremely adequate), deliciousness (1-Extremely unpleasant  
240 to 7-Extremely delicious), and liking (1-Extremely dislike to 7- Extremely like) under both  
241 Real and Virtual environments. All participants answered the same questionnaire, which  
242 only varied in the way it was carried out between the different environments. For the  
243 Virtual context, a 3D digital questionnaire was developed, and the interaction of the user  
244 with the 3D questionnaire was done by means of a natural user interface using the 3D  
245 controllers of the HMD (Oculus Rifts S, Lenovo). In the real context, the panel responses  
246 were recorded on a tablet (10.1" Lenovo Tab E10, Hong Kong, China). Both experiences  
247 did not involve any tasting of the cakes.

## 248 2.5. Questionnaires

249 After evaluation, participants were asked to complete a structured electronic  
250 questionnaire. The questionnaire consisted of several sections dealing with (1)  
251 behavioural and eating habits, based on two previous studies by Márquez-Sandoval et  
252 al. (2014) and Unikel-Santoncini et al. (2004); (2) nutritional knowledge, based on the  
253 study by Parmenter & Wardle (1999); and (3) when the test was carried out in a Virtual  
254 context, as a measure of the sense of presence in the virtual environment, participants  
255 responded to a sense-of-presence questionnaire, based on Slater et al. (1994). Personal  
256 data relating to lifestyle, general interests and socio-demographics were also registered.

## 257 2.6. Statistical Analysis

258 To analyse the collected personal lifestyle, general interest and socio-demographics  
259 data, basic descriptive statistics and variable characterization was carried out.

260 Differences in the visual evaluation of the cakes, relative to the cross-over design were  
261 assessed using linear mixed model analysis of variance (ANOVA) with participants as a  
262 random effect, and order of test session (First vs Second) and type of cake as fixed  
263 factors, where cakes were nested to both the Virtual and Real contexts. Other variables  
264 related to the personal profile of participants such as age, gender, subjective hunger,  
265 sweet tooth preference, eating habits, nutritional knowledge, and presence in the virtual  
266 context were also analysed using a nested ANOVA model. A Fischer LSD post hoc test  
267 was also applied to estimate the differences between groups.

268 An internal preference map was prepared in order to study the relations between the  
269 participants' responses and their expected liking for the samples. The map was carried  
270 out using principal component analysis (PCA) of the correlation matrix of variables for  
271 each cake (objects), followed by a hierarchical cluster analysis (HCA), using Euclidean  
272 distances and Ward's method, to identify groups of participants with different expected  
273 liking. After obtaining the clusters, the individual participants were identified and  
274 represented with different symbols on the previously plotted preference map. To confirm  
275 that they differed from each other, a one-way ANOVA was applied on the mean of the  
276 expected evaluations. To better understand which aspects characterize the different  
277 clusters, a one-way ANOVA analysis was applied to compare cluster means and the  
278 variables related to participants' visual expectations. Moreover, chi-square tests were

1 279 used to verify significant differences between clusters in socio-economic and  
2 280 demographic data.

3 281 Quantitative data were reported as means and standard deviation, and the Fischer (LSD)  
4 282 multiple comparison test was applied to inspect for significant differences in the visual  
5 283 evaluation of cakes, with a 95% confidence level. Significant differences in qualitative  
6 284 data were analysed according to the Chi-square in k proportions test. All data analyses  
7 285 were performed using the XLSTAT statistical software v. 2021.2.1 (Addinsoft, 2020).

### 8 286 3. Results

#### 9 287 10 288 3.1. Influence of crossover design effects and participants' profile factors affecting 11 289 visual evaluation of cakes.

12 290 Differences in participants' visual expectations of the appearance, size, deliciousness,  
13 291 and liking of the five cakes under the two conditions (Real and Virtual context) and the  
14 292 order of the test session (first or second) were analyzed with ANOVA mixed models.  
15 293 Results are presented in Table 1. Only the factors cake (fixed) and participant (random)  
16 294 provide significant information to explain the variability in the visual evaluation of the  
17 295 measured variables.

#### 18 296 \*\*Table 1

19 297 When comparing the data between cakes (Figure 3.1) a similar pattern is shown for the  
20 298 Real and Virtual contexts. The Leonor cake (LC) was evaluated significantly higher  
21 299 ( $p < 0.05$ ) than other cakes in the Virtual environment, for appearance, deliciousness, and  
22 300 expected liking. In both contexts, appearance for Chocomuffin (CM) and Saffron cake  
23 301 (SC) was ranked significantly less than others. A similar pattern was observed for SC  
24 302 regarding serving size.

25 303 Across the experimental contexts, concerning the visual evaluation, no statistically  
26 304 significant differences were observed within cakes (Figure 3.2), except deliciousness for  
27 305 Coulan cake (CC) (discussed below). Therefore, for each type of cake, the Virtual  
28 306 environment neither worsened nor improved assessments when compared to the Real  
29 307 context, indicating the potential of this methodology to be used to rate virtual foods in an  
30 308 immersive environment at the same level as real foods.

#### 31 309 \*\*Figure 3

32 310 Results from the ANOVA model with the socio-demographic participant profile, indicated  
33 311 that only gender, self-declared sweet tooth, and type of cake were significant ( $p < 0.05$ ) in  
34 312 the visual evaluation of real and virtual cakes, while the serving size was not ( $p = 0.238$ ).  
35 313 No significant interactions between these factors were detected (Table 2). Other factors  
36 314 in the model such as age, level of hunger, eating habits, nutritional knowledge, or  
37 315 presence in Virtual context (previously clustered) did not bring significant information to  
38 316 explain the variability in visual expectations. Fischer's post hoc analyses identified  
39 317 differences between groups, also presented in Table 2. Males assessed all variables  
40 318 significantly higher ( $p < 0.05$ ) than females. In the same way, significant differences  
41 319 ( $p < 0.05$ ) were found in participants that self-declared as having a sweet tooth. Among  
42 320 the other factors, type of cake had the most influential effect. No significant differences  
43 321 were found within-cake in the two contexts, except for deliciousness of the CC (Table 2,  
44 322 Figure 3.2), probably due to the color and brightness of the Virtual CC being different  
45 323 from the expected (Spence & Piqueras-Fiszman, 2016). On the other hand, significant  
46 324 differences ( $p < 0.05$ ) were observed between cakes for all visual expectations. In all

325 visual parameters evaluated, SC was the worst ranked and LC obtained higher  
326 evaluation rates.

327 **\*\*Table 2**

### 328 3.2. Participants' expected liking

329 The results obtained from the internal preference map, based on the expected liking  
330 scores of each of the 10 cakes (from virtual and real), yielded four dimensions explaining  
331 66.1% of the variability. The squared cosines associated with the PCA are presented in  
332 Table 3, indicating which cakes are significantly correlated with each PC. Cakes  
333 considered to follow the "Eatertainment" and "Fusion" trends (LC, SC and WC) were well  
334 linked with PC1 (squared cosines varied from 0.57 to 0.36). The CM, considered in the  
335 "Tradition" trend, was aligned with the vertical axis, which was PC2 (squared cosine was  
336 0.65 and 0.38). The CC was associated with PC3 (squares cosines 0.49 and 0.32)  
337 separating the "Indulgence" trend from the others.

338 **\*\*Table 3**

339 The internal preference map for participants with three clusters was obtained after HCA  
340 on the PCs with eigenvalues >1, and confidence ellipses were presented in Figure 4. In  
341 the biplot PC1 vs. PC2 (Figure 4), expected liking vectors of LC, SC and WC (real and  
342 virtual), were closely related to each other, indicating their positive association. In  
343 addition, CM was not associated with these trends of cakes as it was almost orthogonal,  
344 and it was negatively correlated with CC. No differences were observed within cakes  
345 across the contexts.

346 Observing participants' segmentation after HCA, Cluster 1 (C1, n=39), placed mainly on  
347 the bottom-center of the map (Figure 5a), showed better liking expectation for the CC,  
348 and lower for CM. Participants in C1 could be aligned with "Indulgence" values.  
349 Participants in Cluster 2 (C2, n=38) had higher liking expectations for more  
350 "Eatertainment" cakes. Finally, Cluster 3 (C3, n=27) indicated a more traditional group,  
351 with higher expected liking for CM as the "Tradition" value.

352 **\*\*Figure 4.**

353 A one-way ANOVA showed that the three clusters differed significantly ( $p < 0.0001$ ) from  
354 each other with respect to the means of all visual expectations evaluated (Table 4). Three  
355 clusters presented the same approach in all visual evaluations following the expected  
356 liking used to determine HCA after PCA.

357 Cluster 2, with 36.5% of the total 104 participants, mainly linked with the "Eatertainment"  
358 trend, included those who scored the highest in all visual evaluations, as opposed to  
359 Cluster 3 (25.9%), most identified with the "Tradition" trend, which scored the lowest.

360 **\*\*Table 4**

361 From the socio-demographics data analysis, all three clusters presented similar  
362 characteristics (Table 5). No significant differences were detected between them for age,  
363 body mass index (BMI), nationality, educational level, monthly income, or partnership  
364 life. Differences were observed in gender and self-declared sweet tooth. Cluster 3, which  
365 was identified in the PCA as having a greater link with the "Tradition" trend, had a  
366 significantly higher percentage of females and had less of a sweet tooth. Cluster 2,  
367 related to the profile "Eatertainment", was characterized by a significantly higher  
368 percentage of males, and self-declared sweet tooth. No significant overall differences in

369 monthly income were shown between clusters, except for participants who declared high  
370 incomes, where differences between Cluster 2 and Cluster 3 were found to be significant.

371 \*\*Table 5

372 4. Discussion

373 In the last five years, immersive VR environment experiences have been used to study  
374 the effect of the consumption context on participant sensory testing involving food choice  
375 (Cheah et al., 2020; Fang et al., 2021; Goedegebure et al., 2020; Isgin-Atici et al., 2020;  
376 Lombart et al., 2020; Xu et al., 2021) or food evaluation (Ammann et al., 2020; Barbosa  
377 Escobar et al., 2021; Chen et al., 2020; Kong et al., 2020; Korsgaard et al., 2019;  
378 Nivedhan et al., 2020; Stelick et al., 2018; Torrico et al., 2020; Torrico et al., 2021; Wang  
379 et al., 2020; Worch et al., 2020). This work was framed in the application of VR  
380 technologies, where the participant was immersed in the full virtual environment, hence  
381 what is experienced exists only in the virtual world. The same environment and product  
382 were evaluated in a real sensory evaluation booth. To our knowledge, similar work was  
383 implemented by Gouton et al., (2021). In their work, authors compared participants'  
384 visual descriptions of real commercial cookies with their virtualized versions. In this case,  
385 authors concluded that descriptors elicited in visual tests were similar for both real and  
386 virtual experimental conditions. Despite differences in studied participant responses, our  
387 results are in accordance with these authors: no significant differences between cakes  
388 (real or virtual) were found in visual expectations, except for the deliciousness evaluation  
389 for the Coulan cake. Shape and colour (dark chocolate) was a limitation to obtain a  
390 photorealistic texture after virtualization (see figure 2a). This result was in agreement  
391 with results obtained by Zhang & Seo (2015) which observed in an eye-tracking study  
392 that colour and brightness in food pictures influenced participants' visual attention. In the  
393 same way, Zellner et al., (2010, 2014) reflected upon how manipulating colour and  
394 balance in food presentation affected its attractiveness. There are very few studies that  
395 focused on comparing VR and pictures, and there are even fewer that compared food  
396 recreated through virtual reality and food recreated through pictures. Nevertheless, it is  
397 know that the behavior of consumers is more identical to real life when presented with  
398 virtual cues as opposed to pictures (van Herpen et al., 2016). Additionally, it has been  
399 shown that virtual food is as effective as real food, and more effective than photographs  
400 of food, in producing psychological and physiological responses in patients with eating  
401 disorder, suggesting a possible advantage of using virtual stimuli instead of static  
402 pictures as an alternative to real stimuli to induce emotional reactions in subjects. Virtual  
403 food cues elicited similar anxiety levels in participants as those elicited by real food cues,  
404 and higher anxiety than those elicited by picture cues (Gorini et al., 2010).

405 In both experiences (Virtual and Real), only differences between pastries were observed.  
406 Visual perception, mainly colour, influences food expectations in different ways (Spence,  
407 2015, 2018; Wadhvani & McMahon, 2012), playing an important role in expected liking.  
408 The five cakes (real and virtual) presented to participants in this experience had different  
409 visual structures with the colour, gloss, translucency, and surface texture characteristic  
410 of its ingredients, following trends in the pastry market. As mentioned in some  
411 researches, visual attributes impact visual attractiveness and contribute to the  
412 identification of different ingredients, generating taste and flavour expectations and the  
413 quality of pastries (Paakki et al., 2019a; Paakki et al., 2019b), which can justify the  
414 differences found. In the crossover experimental design, participants were divided in two  
415 groups, one group started with the Virtual context and the second group started with the  
416 real one. Each one took part in two sessions and no differences were observed between

417 the first and second session. The results were in line with the ones presented by Gouton  
418 et al. (2021).

419 Gender differences, especially gender stereotypes, have been studied in food (Cavazza  
420 et al., 2015, 2017; Kimura et al., 2009, 2012; Vartanian et al., 2007), but also in the field  
421 of diet and social media (Nelson & Fleming, 2019), online cooking prejudices (Rokicki et  
422 al., 2016), and food choices and behaviours (Fagerli & Wandel, 1999; Grogan et al.,  
423 1997; Roos et al., 1998; Wardle et al., 2004). Most of these studies noted that despite  
424 women having healthier food habits, they paradoxically show higher levels of restrictive  
425 and emotional eating behaviours than men (Basow & Kobryniewicz, 1993; Conner et al.,  
426 2004; Grogan et al., 1997). These differences can be explained not only by differences  
427 in diet but also by cognition and motivation (Wardle et al., 2004) derived from different  
428 social norms, social media pressure to have the perfect body (Pritchard & Cramblitt,  
429 2014), and learning about masculine or feminine eating styles (Cavazza et al., 2020;  
430 Chaiken & Pliner, 1987; Graziani et al., 2021; Rolls et al., 1991). Nutritional value as a  
431 signal of healthy food is also associated to gender roles. In this way food that is high in  
432 calories and fat is related with men, while food low in calories and fat is with women  
433 (Barker et al., 1999). In line with these studies, our results suggest that the visual  
434 evaluation of cakes is conditioned by gender stereotypes, and support the idea that the  
435 gender-based stereotypes about food are more binding for women than for men  
436 (Cavazza et al., 2020). **Similar results were also presented in several studies about  
437 gender differences in eating sweet snacks (Grogan et al., 1997), sandwiches (García-  
438 Segovia et al., 2021), insect-based food alternatives (Caparros et al., 2016) or meat  
439 (Rozin et al., 2012). Cavazza et al. (2015) found that food type, portion size, and dish  
440 presentation influence the perceived association between food and gender.**

441 The portion size effect has been studied by different authors (Sheen et al., 2018)  
442 (Robinson et al., 2015, 2016; Sheen et al., 2018) to relate the increase in portion size in  
443 the last decades with the increase of energy intake. In three experiences designed by  
444 Robinson et al. (2016) to study the effect that visual exposure to larger versus smaller  
445 food portion sizes had on participant perception of a normal portion size, authors did not  
446 find evidence that visual exposure to larger portions altered snack food intake. Contrarily,  
447 studies on nudging have shown that the portion size of chocolate cake and apple slices  
448 may have a clear impact on the amount eaten (Hansen et al., 2016). In our experience,  
449 each cake presented to participants in real or virtual environment had the same portion  
450 size. No differences were found within cakes. Between the cakes, the most traditional  
451 one (Chocomuffin) was evaluated as the most adequate in size. According to our results,  
452 one potential interpretation can be that familiarity affects the importance attributed to the  
453 portion size in traditional cakes (virtual and real). In this sense, an interesting work about  
454 the effect of portion size using virtualized food/environment will be important for future  
455 research.

## 456 5. Limitations

457 These results should be observed with caution because of some limitations of this study.  
458 First, the study used mainly Spanish participants, with a moderate or high level of  
459 education, between the Z-generation and centennials by age, with a healthy weight, and  
460 not being usual users of immersive technologies. In order to generalize this outcome, a  
461 larger and more diverse population should be included in the following steps. Despite no  
462 significant differences being observed by participants for the same cake in each  
463 environment (Real or Virtual), some participants indicated differences in color and  
464 brightness between the virtual representation and the real Coulan cake. Considering that  
465 these effects might influence participants' visual attention (Frey et al., 2008), virtualizing

466 processes for dark and brilliant foods should be improved. On the other hand, in this  
467 work, only visual expectations about appearance, serving size, deliciousness, and liking  
468 were evaluated. To evaluate the complete experience for participants, VR technologies  
469 must continue to evolve. The research team is studying ways to incorporate the use of  
470 multisensory stimuli, such as olfactory, auditive and tasting into further research.

## 471 6. Conclusions

472 This study found that real or virtual environments did not exert a significant influence on  
473 participants' expectations on visual appearance, serving size, deliciousness or expected  
474 liking for Fine Pastry. This result provides insight to design future experiences to  
475 compare how virtual environments (e.g., congruent or incongruent food contexts) could  
476 affect visual expectations or willingness to buy. Immersive technologies could be a viable  
477 alternative for companies to evaluate new food products flexibly and with cost  
478 effectiveness. **Moreover, it demonstrates a reinforcement of the opportunity to use virtual  
479 labs to evaluate perceived expectation towards food products, when consumers are kept  
480 away from the sensory lab, due to COVID-19 or any other circumstance.**

Figure 1. a) Real sensory Booth (at UPV), b) Virtual sensory booth, c) Participant with HDM ready to be immerse in the evaluation.

Figure 2. Real vs. Virtual stimulus designed by “Casa La Curra”: (a) Coulan cake (CC), (b) Leonor cake (LC), (c) Saffron cake (SC), (d) Walnut cake (WC), (e) Chocomuffin (CM).

Figure 3. Mean (LSD) of visual evaluation of five cakes under Real and Virtual conditions: (1) between cakes; (2) within cakes. Abbreviations: CC (Coulan cake), LC (Leonor cake), SC (Saffron cake), WC (Walnut cake), CM (Chocomuffin); R (real cake) and V (virtualized cake) (\*) Only statistically significant differences are marked.

Figure 4. Internal preference mapping based on the visual expected liking ranking biplot PC1-PC2 Abbreviations: CC (Coulan cake), LC (Leonor cake), SC (Saffron cake), WC (Walnut cake), CM (Chocomuffin); R (real cake) and V (virtualized cake)

Table 1.- ANOVA mixed models to test significant differences of fixed and random effects from crossover design.

Source	Type	DF	Appearance		Serving Size		Deliciousness		Expected liking	
			F	p-value	F	p-value	F	p-value	F	p-value
Test session (TS)	Fixed	1	0.081	0.777	0.292	0.589	0.068	0.794	0.016	0.899

Table 3. Principal component analysis squared cosines table for cakes as active variable.

Active Variable	PC1	PC2	PC3	PC4
Chocomuffin_R	0.002	<b>0.378</b>	0.153	0.258
Chocomuffin_V	0.007	<b>0.653</b>	0.030	0.059
Coulan_R	0.074	0.142	<b>0.319</b>	0.166
Coulan_V	0.050	0.093	<b>0.485</b>	0.003
Leonor_R	<b>0.482</b>	0.006	0.056	0.006
Leonor_V	<b>0.566</b>	0.049	0.025	0.065
Saffron_R	<b>0.486</b>	0.037	0.109	0.073
Saffron_V	<b>0.411</b>	0.035	0.011	0.062
Walnut_R	<b>0.358</b>	0.002	0.041	0.148
Walnut_V	<b>0.356</b>	0.010	0.065	0.274

Note: Values in bold correspond for each variable to the PC for which the squared cosine is the largest.

Table 4. Clusters by visual expectations.

	All (N=104)	Cluster1 (N=39)	Cluster2 (N=38)	Cluster3 (N=27)	p-value
		Indulgence	Eaterainment	Tradition	
Appearance*	5.1 (1.3)	5.0 (1.3) <sup>b</sup>	5.5 (1.1) <sup>a</sup>	4.3 (1.4) <sup>c</sup>	<0.0001
Serving size*	4.9 (1.9)	4.7 (1.8) <sup>b</sup>	5.6 (1.6) <sup>a</sup>	3.7 (1.9) <sup>c</sup>	<0.0001
Deliciousness*	5.2 (1.3)	5.1 (1.3) <sup>b</sup>	5.7 (1.1) <sup>a</sup>	4.4 (1.4) <sup>c</sup>	<0.0001
Expected liking*	5.1 (1.4)	4.9 (1.4) <sup>b</sup>	5.7 (0.9) <sup>a</sup>	4.1 (1.3) <sup>c</sup>	<0.0001

\*Mean (SD). Different lower cases in the same line means a significant difference ( $P < 0.05$ ) according to ANOVA one-way and Fischer's LSD post hoc analysis

Table 5. Cluster's characterization according to socio-demographics (only significative differences are marked with superscripts).

		All (N=104)	Cluster1 (N=39)	Cluster2 (N=38)	Cluster3 (N=27)	p- value
			Indulgence	Eatertainment	Tradition	
<b>Gender (%)**</b>	Female	64.4	59.0 <sup>b</sup>	55.3 <sup>b</sup>	85.2 <sup>a</sup>	0.026
	Male	35.6	41.0 <sup>b</sup>	44.7 <sup>a</sup>	14.8 <sup>c</sup>	
<b>Age groups (%)</b>	<25	43.4	41.0	44.7	44.4	0.650
	26-45	30.8	38.5	28.9	22.2	
	>45	26.0	20.5	26.3	33.3	
<b>Nacionality (%)</b>	Spain	88.5	79.5	94.7	92.6	0.165
	European	58.0	7.7	2.6	7.4	
	Latioamerican	5.0	12.8	2.6	0.0	
<b>Education level (%)</b>	Low	5.8	0.0	7.9	3.7	0.576
	Middle	61.5	24.0	65.8	55.6	
	High	34.6	38.5	26.3	40.7	
<b>Monthly income (%)</b>	Low (<1000 €)	43.2	43.6	47.3	37.0	0.087
	Middle (1000-2000€)	29.8	28.2	39.5	18.5	
	High (> 2000€)	19.2	20.5 <sup>ab</sup>	7.9 <sup>b</sup>	33.3 <sup>a</sup>	
	NA	7.7	7.7	5.3	11.1	
<b>Partnership life (%)</b>	Along	7.7	15.4	2.6	3.7	0.515
	In couple	23.1	23.1	26.3	18.5	
	In family	49.0	41.0	52.6	55.6	
	Shared apartment	19.2	17.9	18.4	22.2	
	NA	1.0	2.6	0.0	0.0	
<b>Sweet Tooth (%)**</b>	Yes	78.8	84.6 <sup>b</sup>	86.8 <sup>a</sup>	59.3 <sup>c</sup>	0.024
	No	21.2	15.4 <sup>a</sup>	13.2 <sup>a</sup>	40.7 <sup>b</sup>	
<b>Age*</b>		34 (14)	33(13) <sup>a</sup>	34(14) <sup>a</sup>	35(14) <sup>a</sup>	0.803
<b>BMI*</b>		24(3)	24(3) <sup>a</sup>	24(3) <sup>a</sup>	23(2) <sup>a</sup>	0.187
<b>Subjective hunger level at the start of the experiment * (scale 1 "not hungry" to 7"very hungry")</b>		3.5 (1.6)	3.3 (1.5) <sup>a</sup>	3.7 (1.6) <sup>a</sup>	3.5 (1.5) <sup>a</sup>	0.827

\*Mean (SD). Similar superscripts in the same line means a no significant difference ( $P < 0.05$ ) according to ANOVA one-way and Fischer's LSD post hoc analysis

\*\*Different lower cases in the same line mean a significant difference ( $P < 0.05$ ) according to Chi-square in k proportions test.
