

Enabling the Green Total Factor Productivity of the Construction Industry with the Prospect of Digital Transformation

Abstract: This research study adopts 30 provinces, municipalities and autonomous regions in China as the research object in order to explore the green total factor productivity (GTFP) of the construction industry with the prospect of digital transformation. Based on construction industry panel data from 2011-2017, the CCR model and PCE model evaluation model are used to measure the GTFP of the construction industry in the context of digital transformation. The results of the research study identify the following: (A) The PCE model was able to differentiate all decision units and complete ranking. (B) The GTFP of the construction industry in East, North, South-Central, and Southwest China is relatively high, while that in Northeast and Northwest China is low. Thus, there is room for improvement in Northeast and Northwest China to a certain extent. (C) The higher the optimism of decision makers about the digital transformation of the construction industry is, the higher the GTFP of the construction industry; additionally, when decision makers become increasingly more optimistic about the digital transformation of the construction industry, the GTFP of the construction industry decreases to a certain extent, while when decision makers become increasingly less optimistic about the digital transformation of the construction industry, the GTFP of the construction industry increases to a certain extent.

Keywords: Digital transformation; Prospect theory; Construction industry; Green total factor productivity (GTFP).

1 Introduction

Since the reform and opening up more than 40 years ago, China's economy has developed rapidly, leading to the emergence of the 'Chinese economic miracle'^[1], which has attracted worldwide attention. However, this rapid growth of China's economy has come at the expense of the environment. The development path of high investment, high consumption and high pollution has become a "bottleneck" for sustainable economic development. As an important sector of the national economy, the construction industry is no exception[2]. Moreover, digital and green development has become an inevitable trend in the development of the construction industry[3]. With the innovative breakthrough and integrated development of the new generation of information

32 and communication technology (ICT), digital technologies that build on building information
33 modelling (BIM) are becoming the driving force behind the transformation, upgrading and
34 sustainable development of the construction industry[4].

35 'Digital transformation' is a concept based on harnessing the latest digital technologies (such
36 as cloud computing, big data, artificial intelligence, Internet-of-Things, robotics, and blockchain)
37 and related capabilities to drive organizational business model innovation and business ecosystem
38 reconstruction. Indeed, digital transformation can be viewed as moving beyond more traditional
39 information technology (IT) implementations focused on process automation and optimization
40 through enabling changes and resulting implications for products, services, and business models as
41 a whole^[5]. With the development of a new generation of IT and the increase in the availability of
42 innovative technologies, such as big data, artificial intelligence and cloud computing, digital
43 transformation is enabling the creation of new value creation paths in order to facilitate
44 organizational change and concomitantly drive disruptions, such as driving consumer behaviours
45 and creating new competitive landscapes[6].However, digital transformation in the construction
46 industry is currently still its infancy and while many have advocated the potential benefits[7-11]
47 there is now a pressing need to investigate the prospect of digital technologies in the construction
48 industry. Furthermore, digital transformation has also been viewed as an important emerging enabler
49 to improve the sustainability of the construction sector[12, 13] and thereby generate improved
50 performance for the industry across economic, environmental and social outcomes. Therefore, this
51 research study has adopted the Chinese construction industry as the object of an empirical
52 investigation of industry panel data from 2011-2017 in order to utilize the prospect cross-efficiency
53 evaluation model is used to measure the green total factor productivity of the construction industry
54 with the prospect of digital transformation.

55 First,the existing articles seldom pay attention to the influence of digitalization on total factor
56 productivity, so this paper expands the existing research. Second,this paper adopts the PCE model
57 based on prospect theory, which not only overcomes the disadvantage that some evaluation units can
58 not be further distinguished because the traditional DEA model always evaluates the efficiency value
59 from its own perspective, but also solves the problem that the traditional cross-efficiency model does
60 not fully consider the subjective preference of decision makers in the process of efficiency evaluation,
61 can not reflect the different risk attitudes of decision makers when they face the benefits and losses,
62 and is difficult to meet the actual decision-making needs of decision makers. Third,this study

63 systematically combs the existing research, and concludes that the input index and output index of
64 total factor productivity improve the reliability of the research as much as possible. Finally, the
65 results of this study are helpful for the government to evaluate the prospect of GTFP digital
66 transformation in construction industry.

67 The paper is organized as follows. Section 2 presents the literature review. Then, methodology
68 is presented in Section 3. Section 4 shows the empirical results, with Section 5 discussing these
69 results. Finally, conclusions are made in Section 6.

70

71 **2 Literature review**

72 **2.1 Digital transformation in the construction industry**

73 In recent years, the topic of digital transformation has aroused the attention of the business
74 management community [14]. Indeed, industries are actively embracing digital transformation,
75 including the automotive industry [15], food industry [16], fashion industry [17], aerospace
76 industry [18] as well as the construction industry [19]. In the case of the construction industry, digital
77 transformation can be viewed as building on the use of building information modeling (BIM) that
78 acts as a big data platform in the architecture, engineering, and construction (AEC) industry and to
79 support the transition to a smart industrial paradigm [20].

80 Extending the functionality of BIM usage in the construction sector offers the capability to
81 provide improved efficiencies across different aspects of the industry and this has also been
82 articulated in terms of the paradigm of Construction 4.0 [21]. For instance, BIM systems can be
83 extended through incorporating material databases along with corresponding use of big data, smart
84 sensors and increasing levels of automation in order to improve the efficiency and safety of the
85 construction of roads incorporating recycled materials [22]. This extension can also be considered
86 in terms of moving beyond purely the construction stage, since it has been identified that IoT
87 (internet-of-things)-BIM systems can be deployed to whole life benefits for FM (facilities
88 management) and the built environment applications, namely energy management, operations and
89 maintenance management, space management, FM project management, emergency management
90 and quality management [23]. While yet other options also exist in regard to utilizing BIM to secure
91 sustainability related benefits, such as improved energy efficiency in the built environment [24].

92 In regard to the technological dimension of digital transformation, there are opportunities to
93 utilize various technologies, such as artificial intelligence [25], IoT and big data [26], augmented
94 and virtual reality [27], robotics [28] as well as additive manufacturing [29]. There are also a number
95 of more emerging technologies that can be considered as part of digital transformation in the
96 construction sector. In this regard, blockchain systems based on distributed ledger technology have
97 been identified as having a number of potential applications in the construction industry[30]. This
98 includes enabling higher levels of productivity through adopting situational instances of Payments
99 in Project Management (PPM) and Procurements in Supply Chain Management (PSCM) as well as
100 harnessing BIM to underpin using Smart Asset Management (SAM) [31]. Whereas digital twins
101 have been evaluated as having application to workforce safety in the construction industry [32] and
102 explored as providing improved capabilities for construction site logistics [33].
103

104 From an international perspective and in the case of Nigeria, Ezeokoli et al. ^[34] investigated the
105 opinions of construction sector professionals on the digital transformation of the construction
106 industry; the study showed that 69% and 12% of professionals believe that digital transformation is
107 an opportunity and a threat, respectively, while 19% of professionals believe that it is both. Whereas,
108 Kraatz et al.[35] have described the productivity benefits in the Australian transport infrastructure
109 sector through the construction industry adopting BIM, virtual design and construction (VDC) and
110 integrated project delivery (IPD) systems. Koseoglu et al. [36] carried out research on the BIM-
111 Enabled Digital Transformation of a new airport project in Istanbul, Turkey, finding that the major
112 challenges involve sustaining continuous monitoring and controlling the project execution phase as
113 well as managing engineering complexity while remaining aligned with the BIM learning curves of
114 key stakeholders. The researchers also identified that more strategic level control measures,
115 incentivized virtual systems to enable collaborative working and ongoing digital delivery
116 mechanisms can be viewed as enablers of digital transformation on infrastructure projects. Hwang
117 et al. [37] investigated the implementation status and project performance in the Singapore
118 construction industry through integrated digital delivery (IDD) and found that IDD implementation
119 resulted in a number of benefits for the sector, including improved overall project, project cost,
120 project quality and project schedule performance. In other work, Pfnür and Wagner[38] identified
121 three impact mechanisms of the digital transformation in the real estate industry in Germany, which
122 is based on the perspectives of occupiers (concerned with access to more flexible space), service

123 providers (concerned with increasing the efficiency of traditional processes) and investors
124 (acknowledging the needs of the occupiers but not necessarily pursuing resulting strategies.

125

126 **2.2 Green total factor productivity**

127 In the construction industry, green total factor productivity (GTFP) is an intuitive manifestation
128 of economic growth through considering energy consumption and carbon emissions. Indeed, it can
129 be argued that GTFP reflects the real green growth performance indicators of the economic system
130 during a certain period of time. In this regard, a systematic analysis of the GTFP of the construction
131 industry enables the evaluation of the development status of the construction industry[39]. Research
132 on GTFP originated in the middle and late 20th century and was developed during the first ten years
133 of the 21st century[40].

134 The current research on this topic focuses on the measurement of GTFP in the construction
135 industry. The parameter estimation method using the Solow residual value[41], stochastic frontier
136 analysis (SFA) method[42] and the nonparametric data envelopment analysis (DEA)[43] have all
137 been widely used. DEA is more popular among scholars due to its advantages in dealing with
138 multiple inputs and outputs. In 1983, Pittman used DEA for the first time to study GTFP considering
139 poor output. Ebrahimi and Salehi[39] used DEA to calculate technical efficiency, pure technical
140 efficiency, scale efficiency, and cross-efficiency to discuss carbon dioxide emission reduction and
141 improve energy efficiency. Hu et al.[44], based on the Malmquist index of DEA and sequential
142 benchmark technology, proposed an index for evaluating carbon emission performance in the
143 framework of TFG. Whereas Xiang et al.[4] used the global Malmquist-Luenberger model to
144 measure the GTFP of the construction industry. Although scholars have conducted extensive
145 research on the GTFP of the construction industry, there is a lack of research on the prospect of
146 digital transformation in this sector. Therefore, empirical research is required on whether digital
147 transformation can engender greater benefits to the construction industry. Such research also needs
148 to identify the role that digital transformation can play in resource conservation and whether it can
149 improve the GTFP of the construction industry.

150 **3 Research methods**

151 **3.1 Research strategy**

152 In order to address the gap in the knowledge base identified in the literature review, this research
153 study uses the prospect cross-efficiency (PCE) model to measure the GTFP of the construction

154 industry with the prospect of digital transformation. The model deploys a self-evaluation system to
 155 alleviate the drawbacks of the traditional method of relying solely on the self-evaluation system for
 156 the evaluation of decision-making units (DMUs). This approach determines that the globally optimal
 157 DMU has achieved the goal of fully ranking all DMUs. The model has been used to describe the
 158 degree of optimism of decision makers regarding the prospect of the digital transformation of the
 159 construction industry in a cross-efficiency evaluation and analyses the six major regions of China
 160 for the construction industry from 2011 to 2017. This is achieved by changing the parameter value
 161 representing the degree of optimism of decision makers about the prospect of the digital
 162 transformation of the construction industry (excluding the GTFP of Tibet, Hong Kong, Macao and
 163 Taiwan regions) to compare the ranking of the GTFP of the construction industry in various regions
 164 under different parameter values. This study uses a systematic GTFP measurement model to
 165 comprehensively and accurately measure the GTFP of the construction industry. The study thereby
 166 enhances the application of GTFP in the construction industry and provides a reference for research
 167 on GTFP in other industries. Furthermore, the study explores the impact of the prospect of digital
 168 transformation on GTFP in the construction industry.

169

170 3.2 CCR model of self-efficiency evaluation

171 Assuming that $D=\{DMU_1, DMU_2, \dots, DMU_n\}$ is a set of n evaluated DMUs, each DMU
 172 generates s outputs by consuming m inputs. Let $N=\{1,2,3,\dots,n\}$, $k \in N$; $M=\{1,2,3,\dots,m\}$, $i \in M$; and
 173 $S=\{1,2,3,\dots,s\}$, $r \in S$. For DMU_k , $k=1, 2, 3,\dots,n$, input is defined as X_{ik} ($i=1, 2,\dots,m$), and output is
 174 defined as Y_{rk} ($r=1, 2, 3,\dots,s$); see Table 1. The relative efficiency of DMU_k is defined as follows:

$$175 \quad E_{kk} = \sum_{r=1}^s u_{rk} Y_{rk} / \sum_{i=1}^m v_{ik} X_{ik} \quad (1)$$

176 where u_{rk} and v_{ik} are the nonnegative weights of s outputs and m inputs, respectively. In the
 177 self-efficiency evaluation, the relative efficiency of 3 compared to other DMUs can be measured
 178 with the following Charnes–Cooper–Rhodes (CCR) model:

$$179 \quad \max E_{kk} = \sum_{r=1}^s u_{rk} Y_{rk} / \sum_{i=1}^m v_{ik} X_{ik}$$

$$180 \quad \text{s.t. } \sum_{r=1}^s u_{rk} Y_{rj} / \sum_{i=1}^m v_{ik} X_{ij} \leq 1, \quad j \in N$$

$$181 \quad u_{rk}, v_{ik} \geq 0 \quad r \in S, i \in M \quad (2)$$

182 Model (2) is a nonlinear programming model. To facilitate the solution, this section uses the
 183 CCR model to transform Model (2) into the following linear programming model:

$$\begin{aligned}
 184 \quad & \max E_{kk} = \sum_{r=1}^s u_{rk} y_{rk} \\
 185 \quad & \text{s.t. } \sum_{r=1}^s u_{rk} y_{rj} - \sum_{i=1}^m v_{ik} x_{ij} \leq 0, \quad j \in N \\
 186 \quad & \sum_{i=1}^m v_{ik} x_{ik} = 1 \\
 187 \quad & u_{rk}, v_{ik} \geq 0 \quad r \in S, i \in M \quad (3)
 \end{aligned}$$

188 where u_{rk}^* and v_{ik}^* are the optimal output and input weights, respectively, and $E_{kk}^* =$
 189 $\sum_{r=1}^s u_{rk}^* y_{rk}$ is the CCR efficiency of DMU_k , which represents the best relative efficiency of
 190 DMU_k calculated through self-evaluation. If $E_{kk}^* = 1$ and optimal weights u_{rk}^* and v_{ik}^* are
 191 positive, then 6 is valid; otherwise, it is invalid.

192 **Table 1 Input-output value of DMUs**

DMU _s	DMU ₁	DMU ₂	DMU _n
Output values	y_{11}	y_{12}	y_{1n}
	y_{21}	y_{22}	y_{2n}

	y_{s1}	y_{s2}	y_{sn}
Input values	x_{11}	x_{12}	x_{1n}
	x_{21}	x_{22}	x_{2n}

	x_{m1}	x_{m2}	x_{mn}

193

194 3.3 CCR model of cross-efficiency evaluation

195 In Model (3), each DMU is evaluated with the optimal weight, which may lead to a CCR
 196 efficiency value of 1 for many DMU self-efficiency evaluations, which cannot be further
 197 distinguished. To compensate for this shortcoming, Sexton et al. ^[12] proposed a cross-efficiency
 198 evaluation CCR model, which evaluates the overall performance of each DMU by using the total
 199 weight of all DMUs. If u_{rk}^* and v_{ik}^* are the optimal weights of the output and input,
 200 respectively, of DMU_k given by Model (3), then the cross-efficiency score of DMU_d is as follows:

$$201 \quad E_{dk} = \frac{\sum_{r=1}^s u_{rk} y_{rd}}{\sum_{i=1}^m v_{ik} x_{id}}, \quad d \in N, d \neq k \quad (4)$$

202 For each DMU_k , Model (3) is calculated n times each time, and each DMU obtains n-1
 203 crossover efficiency and optimal self-efficiency. Moreover, n DMUs can obtain n groups of input-
 204 output weights using n*n crossover. In terms of the efficiency matrix, the diagonal elements in Table
 205 2 present the CCR efficiency score of self-efficiency evaluation, E_{kk}^* .

206 To evaluate the overall performance of each DMU and calculate the average cross-efficiency of
 207 each row (see Table 2), the cross-efficiency of DMU_d is defined as follows:

208

$$E_d = \sum_{k=1}^n E_{dk} / n, \quad d \in N \quad (5)$$

209

Cross-efficiency score E_d provides a peer-to-peer evaluation of DMU_d , and accordingly, these n DMUs can be completely compared or ranked.

211

Table 2 Cross-efficiency matrix of DMUs

DMU	Target DMU				Average cross-efficiency
	DMU ₁	DMU ₂	DMU _n	
DMU ₁	E_{11}	E_{12}	E_{1n}	$\sum_{k=1}^n E_{1k} / n$
DMU ₂	E_{21}	E_{22}	E_{2n}	$\sum_{k=1}^n E_{2k} / n$
.....
DMU _n	E_{n1}	E_{n2}	E_{n3}	$\sum_{k=1}^n E_{nk} / n$

212

213 3.4 Prospect theory

214

In 1979, Kahneman and Tversky proposed the prospect theory ^[13]. As a descriptive theory about the decision-making behaviour of risky individuals, prospect theory has been regarded as one of the most influential behavioural decision-making theories ^[14]. Moreover, prospect theory involves the following important principles ^[13].

218

(1) Reference dependence, where a decision maker usually perceives a gain or loss according to a reference point; therefore, the decision maker's foreground value curve is divided into a gain domain and a loss domain on the basis of this reference point.

221

(2) Loss aversion, where a decision maker is more sensitive to loss than to gain. For this reason, the loss domain of the foreground value curve is steeper than the gain domain.

223

(3) Sensitivity reduction, where a decision maker shows a profit trend of avoiding risk and a loss trend of seeking risk. Correspondingly, the foreground value curve is concave in the gain domain and convex in the loss domain.

226

The functional aspect of prospect theory is described as follows:

227

$$V(\Delta Z) = \begin{cases} (\Delta Z)^\alpha, & (\Delta Z \geq 0) \\ -\theta(-\Delta Z)^\beta, & (\Delta Z < 0) \end{cases} \quad (6)$$

228

ΔZ is used to measure the deviation of Z from reference point Z_0 . If $\Delta Z \geq 0$, then the result is regarded as a gain; otherwise, the result is regarded as a loss ($\Delta Z < 0$). Parameters $0 < \alpha < 1$ and $0 < \beta < 1$ indicate the convexity of the value function in the gain and loss domains, respectively, θ indicates the loss avoidance coefficient, and $\theta > 1$ indicates that the loss area value function is steeper than the gain area value function.

232

233 Existing cross-efficiency evaluation methods assume that a decision maker is completely
 234 rational and usually belongs to the theoretical framework of expected utility. Noting that prospect
 235 theory is very consistent with the actual decision-making behaviour of human beings, the following
 236 section proposes a new cross-efficiency evaluation model based on prospect theory.

237

238 3.5 PCE model

239 Prospect theory reveals that a decision maker usually reflects the quality of results according to
 240 a reference point. The selection method for the reference point considers the following points: zero
 241 value, average value, median value, worst value and best value. This study is based on prospect
 242 theory and chooses the best and worst values. The worst DMU usually consumes the most input and
 243 produces the least output, and the best DMU usually consumes the least input and produces the most
 244 output. In prospect theory, if the value of a DMU is higher than that of the worst DMU, then it is
 245 viewed as a return. Relative loss can be regarded as a lower value than the optimal DMU, in which
 246 case, the DMU is regarded as a loss.

247 If the reference point is the worst DMU, then the foreground gain of the i -th input of DMU_k
 248 and the r -th output is $V_{I_{ik}}^+ = (x_i^- - x_{ik})^\alpha$ and $V_{O_{rk}}^+ = (y_{rk} - y_r^-)^\alpha$, respectively, among which
 249 $x_i^- = \max\{x_{ik}\}$ and $y_r^- = \min\{y_{rk}\}$.

250 If the reference point is the best DMU, then the prospect loss of the i -th input of DMU_k and the
 251 r -th output is $V_{I_{ik}}^- = -\theta(x_{ik} - x_i^+)^\beta$ and $V_{O_{rk}}^- = -\theta(y_r^+ - y_{rk})^\beta$, respectively, among which
 252 $x_i^+ = \min\{x_{ik}\}$ and $y_r^+ = \max\{y_{rk}\}$.

253 Suppose that $N = \{1, 2, \dots, n\}$, $k \in N$, $M = \{1, 2, \dots, m\}$, $i \in M$, and $S = \{1, 2, \dots, s\}$, for $r \in S$,
 254 and that there are n DMUs to be evaluated; the output and input of DMU_k ($k \in N$) are y_{rk} ($r \in S$)
 255 and x_{ik} ($i \in M$), respectively. Thus, a PCE model is constructed as follows:

$$256 \quad \max \lambda (\sum_{r=1}^s u_{rk} (y_{rk} - y_r^-)^\alpha + \sum_{i=1}^m v_{ik} (x_i^- - x_{ik})^\alpha)$$

$$257 \quad - (1-\lambda) (\sum_{r=1}^s u_{rk} \theta((y_r^+ - y_{rk})^\beta) + \sum_{i=1}^m v_{ik} \theta(x_{ik} - x_i^+)^\beta)$$

$$258 \quad \text{s.t. } \sum_{i=1}^m v_{ik} x_{ik} = 1$$

$$259 \quad \sum_{r=1}^s u_{rk} y_{rk} = E_{kk}^*$$

$$260 \quad \sum_{r=1}^s u_{rk} y_{rj} - \sum_{i=1}^m v_{ik} x_{ij} \leq 0 \quad j \in N$$

$$261 \quad u_{rk}, v_{ik} \geq 0, \quad r \in S \quad i \in M \quad (7)$$

262 Parameter λ represents the relative importance of the gain that satisfies $0 \leq \lambda \leq 1$. In the PCE
 263 model, different λ values represent different attitudes of decision makers. If $0 \leq \lambda < 0.5$, then the
 264 decision maker will pay more attention to a loss rather than a gain; if $\lambda = 0.5$, then the decision maker
 265 will consider the factors of gain and loss equally important; and if $0.5 < \lambda \leq 1$, then the decision maker
 266 will pay great attention to the gain preference.

267 Parameter α represents the concavity of the value function in the gain area, which indicates the
 268 degree of optimism of the decision maker about the digital transformation of the construction
 269 industry. A larger α value means that the decision maker is very optimistic about the digital
 270 transformation of the construction industry. At this time, the decision maker is looking for risks.
 271 When α tends towards 0, the decision maker avoids risks in the evaluation process, and the evaluation
 272 results of the corresponding PCE model are quite conservative. Parameter β represents the convexity
 273 of the internal value function of the loss area, which represents the degree of the decision maker's
 274 disapproval of the digital transformation of the construction industry. A larger β value means that
 275 the decision maker is very dissatisfied with the digital transformation of the construction industry.
 276 At this time, the decision maker is sensitive to losses. When β tends towards 0, the decision maker
 277 seeks risks in the evaluation process, and the evaluation results of the corresponding PCE model are
 278 quite risky.

279

280 3.6 Data and evaluation index system

281 The DMUs in the model are the provinces, municipalities and autonomous regions examined in
 282 this study, which selects the construction industry panel data of 30 provinces, municipalities, and
 283 autonomous regions from 2011-2017 in China. The data used in this study mainly come from the
 284 "China Statistical Yearbook", "China Energy Statistical Yearbook", "China Construction Statistical
 285 Yearbook" and the relevant statistical yearbooks of various provinces and regions in China. Other
 286 data come from the following website; <http://cyfd.cnki.com.cn/>. Due to lack of data availability and
 287 completeness, relevant data for the Tibet Autonomous Region were excluded.

288 In order to select appropriate indicators, this study refers to the selection of input-output
 289 variables in the existing research on GTFP in the construction industry, as shown in Table 3.

290 **Table 3 Existing GTFP evaluation index system for the construction industry**

Author	Years	Investment index	Output indicators
Li and Liu	2010	(1) Labour (2) Capital	(1) Total value added
Wang et al.	2011	(1) Labour (2) Capital	(1) Total value added
Liu et al.	2013	(1) Labour (2) Capital	(1) Value added
He	2013	(1) Labour (2) Capital (3) Mechanical value of labour per capita	(1) Total value added (2) Total profit and taxes (3) Overall labour productivity

Li et al.	2014	(1) Labour (2) Capital (3) Number of enterprises (4) Mechanical value of labour per capita	(1) Total income of the enterprise (2) Completed construction area
Shi et al.	2016	(1) Capital (2) Operational investment	(1) Total profit (2) Project settlement profit
Hu and Liu	2016	(1) Labour (2) Completed construction (3) Energy	(1) Total value added
Hu and Liu	2017	(1) Labour (2) Completed construction	(1) Total value added (2) Carbon dioxide emissions
Chen et al.	2018	(1) Labour (2) Equipment	(1) Value added (2) Total value added (3) Total profit and tax
Hu and Liu	2018	(1) Labour (2) Capital (3) Equipment	(1) Total value added
Huo et al.	2018	(1) Labour (2) Capital (3) Equipment (4) Energy	(1) Total added value (2) Completed construction area

291 This study examined the existing evaluation indicators of GTFP in the construction industry.
 292 Subsequently, four input variables as well as two output variables and one undesired output variable
 293 were selected and digital transformation was established. Table 4 presents the prospective evaluation
 294 index system for the GTFP of the construction industry.

295 **Table 4 GTFP Evaluation Index System of the Construction Industry**

Index	Type	Unit
Number of employees in construction enterprises	Input	Millions
Total assets of construction enterprises	Input	Billions
Total power of construction machinery	Input	10 ⁴ kw
Building energy consumption	Input	Ten thousand tons
Total output value of the construction industry	Expected output	Billions
Total profit of the construction industry	Expected output	Billions
Carbon dioxide emissions	Undesired output	Ten thousand tons

296 4 Results and Analysis

297 This empirical study takes the construction industry of 30 provinces, municipalities and
 298 autonomous regions in China from 2011 to 2017 as the research object. Taking the digital
 299 transformation of the construction industry as the prospect, the CCR model and the PCE model are
 300 used to measure the GTFP of the construction industry, and the GTFP of the construction industry
 301 with the prospect of digital transformation is measured. The two models are compared and subjected
 302 to sensitivity analysis, and the following conclusions are drawn.

303

304 4.1 Evaluation Results of the CCR Model

305 It is useful to present an illustrative example of the evaluation results from 2016. The evaluation
 306 results for the other years could be obtained in the same way. Based on the input-output data of the
 307 construction industry in 2016, the efficiency values of 30 DMUs were calculated by the CCR model
 308 (self-efficiency evaluation). The results are provided in last column of Table 5. According to Table

309 5, the efficiency value of most DMUs is 1, signifying that they are effective and that each DMU
310 cannot be further distinguished. Therefore, the PCE model was introduced to calculate the cross-
311 efficiency value of each DMU to comprehensively rank all DMUs.
312

Table 5 Input-Output of the Construction Industry in 2016

This study followed the research of scholars Zhang et al. [15] through aiming to further reveal

DMU	Input					Output		Efficiency of the CCR model
	Labours	Total assets	Total power of construction machinery and equipment	Energy consumption	Carbon dioxide emissions	Total output value	Gross profit

the differences in the spatial distribution of GTFP in the construction industry. Therefore, the 30

provinces and cities were divided into six regions based on their geographical location and economic

317 development level, namely, East, South-Central, North, Northeast, Southwest, and Northwest China.
 318 Specifically, East China includes Shandong, Jiangsu, Anhui, Jiangxi, Zhejiang, Fujian, and Shanghai;
 319 South-Central China refers to Henan, Hubei, Hunan, Guangxi, Guangdong, and Hainan; North China
 320 includes Inner Mongolia, Beijing, Tianjin, Hebei, and Shanxi; Northeast China contains
 321 Heilongjiang, Jilin, and Liaoning; Southwest China includes Sichuan, Chongqing, Yunnan, and
 322 Guizhou; and Northwest China contains Xinjiang, Qinghai, Gansu, Ningxia, and Shaanxi China. See
 323 Fig. 1 for the specific division of regions in China.

324
 325 **Fig. 1 Division of the Six Regions**

326 **Table 6 CCR Efficiency Values of the Regional Construction Industry during 2011-2017**

Area \ Year	2011	2012	2013	2014	2015	2016	2017	Average
East China	0.907	0.918	0.929	0.924	0.905	0.949	0.894	0.918
South-Central China	0.919	0.944	0.948	0.956	0.958	0.970	0.956	0.950
North China	0.951	0.990	0.990	0.971	0.965	0.894	0.968	0.961
Northeast China	0.931	0.933	0.940	0.920	0.876	0.849	0.866	0.902
Southwest China	1.000	0.973	0.992	0.998	0.873	0.820	0.848	0.929

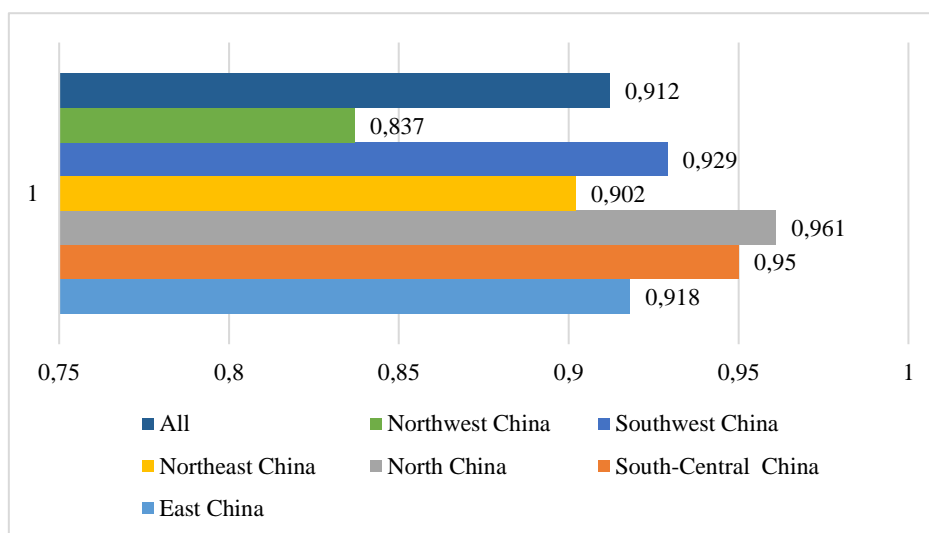

Fig. 2 CCR Average Efficiency Value of the Regional Construction Industry

327
328

329 Table 5 shows the CCR efficiency value of the construction industry in 2016, and similarly such
 330 data can also be obtained for the period 2011-2017, the results are shown in Table 6. In fact, the
 331 CCR efficiency values of the construction industry were analysed for the years 2011-2017 from the
 332 regional perspective (as shown in Fig. 2), which clearly highlights that the average CCR efficiency
 333 during the study period was 0.912. In particular, the average CCR efficiency of East, North, South-
 334 Central, and Southwest China was higher than that of the whole country and investment in the
 335 construction industry in these regions is lower than that in other regions. This indicates that during
 336 the study period, the GTFP value of the construction industry in East, North, South-Central and
 337 Southwest China were higher, while those of the construction industry in Northeast and Northwest
 338 China were lower. Thus, there is room for improvement in Northeast and Northwest China to a
 339 certain extent.

340

341 **4.2.Evaluation results of the PCE model**

342 It was believed that the digital transformation of the construction industry would arrive
 343 as expected ($\lambda=0.5$). Other parameters, α , β and θ , in the model were 0.89, 0.92 and 2.25,
 344 respectively. The input-output weight of the construction industry was calculated in
 345 accordance with the CCR efficiency of self-evaluation in the first step and the PCE model, as
 346 shown in Table 7.

347
348

Table 7 Input-Output Weights of the Construction Industry

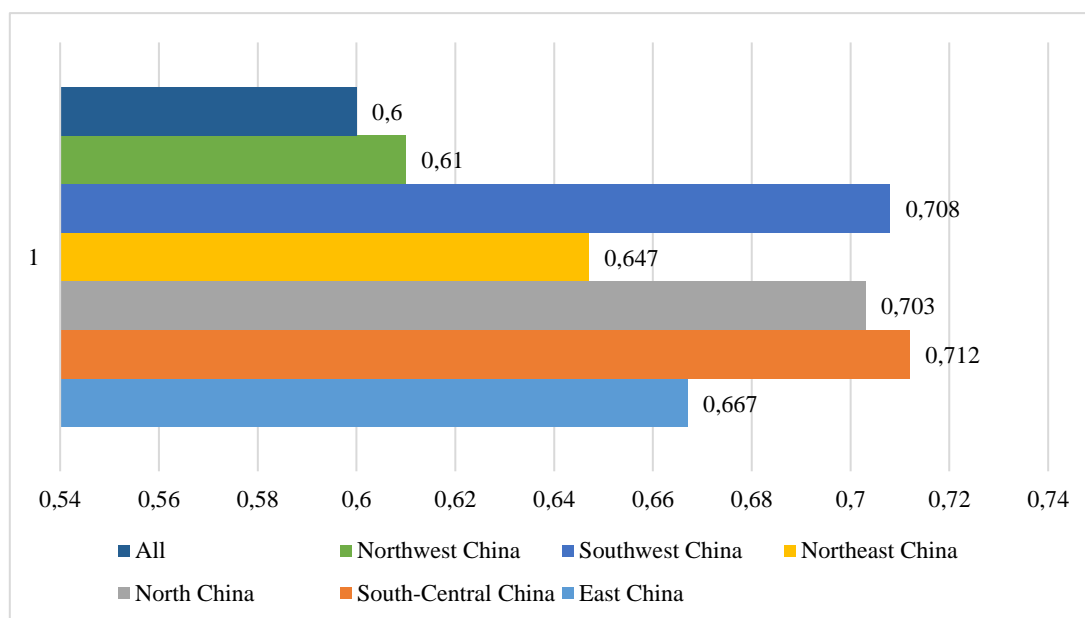

DMU	Weight of Input					Weight of Output

350 According to Table 7 (input-output weights) and Table 5 (construction industry input-output),
351 the cross-efficiency matrix of the construction industry can be obtained. The average cross-efficiency
352 of each row of the matrix is calculated, reflecting the overall efficiency of the construction industry.

353 Moreover, this study explored the cross-efficiency value in six regions and obtained their ranking
 354 order.

355 **Table 8 Regional Efficiency Value of the Construction Industry during 2011-2017**

Year Area	2011	2012	2013	2014	2015	2016	2017	Average
East China	0.609	0.636	0.667	0.673	0.696	0.690	0.697	0.667
South-Central China	0.652	0.681	0.680	0.700	0.751	0.751	0.772	0.712
North China	0.624	0.670	0.703	0.701	0.729	0.728	0.762	0.703
Northeast China	0.575	0.615	0.672	0.659	0.673	0.670	0.662	0.647
Southwest China	0.792	0.756	0.762	0.757	0.641	0.626	0.625	0.708
Northwest China	0.513	0.553	0.617	0.625	0.665	0.650	0.648	0.610
All	0.609	0.636	0.667	0.673	0.696	0.690	0.697	0.600

356 **Fig. 3 Regional Average Efficiency Value of the Construction Industry**

357 The PCE model was applied to measure the efficiency values of China's construction industry
 358 during 2011-2017, which are provided in Table 5. First and foremost, this study analysed the
 359 efficiency value during the period 2011-2017 from the regional perspective (as shown in Fig. 3).
 360 According to the Fig. 3, the average efficiency is 0.600 across the entire nation. However, in South-
 361 Central, Southwest and North China, the efficiency value is the highest because these regions are the
 362 most developed and actively promote the construction industry. In contrast, the value is the lowest
 363 in Northeast and Northwest China, and consequently there is scope for these regions to encourage
 364 greater levels of capital investment and thereby enhance the construction industry. As indicated by
 365 the analysis, the results calculated by the PCE model are consistent with those calculated by the CCR
 366 model.
 367

368 **4.3. Comparison of the CCR and PCE models**

369 In this part of the study, the construction industry in 2016 is taken as an illustrative example,
 370 and the impact of the CCR and PCE models on the efficiency value of the construction industry in
 371 the six regions studied are compared and analysed. Additionally, the sensitivity of the evaluation
 372 results is analysed. Table 9 provides the efficiency values of the 30 provinces and cities in these six
 373 regions in 2016. In order to more intuitively display the efficiency values calculated by the CCR and
 374 PCE models, this study adopted a line graph to show the changes in these values, as shown in Fig.
 375 4. It is clearly shown from Fig. 4 that the efficiency value calculated by the PCE model is lower than
 376 that calculated by the CCR model because the PCE model evaluates the efficiency value in two
 377 stages and performs self-evaluation with a set of the best weighting coefficients. At the same time,
 378 the weighting coefficients of other DMUs are used for peer evaluation. Furthermore, the efficiency
 379 values of East, South-Central, and North China are higher, signifying that the economic growth of
 380 the construction industry in these regions has changed from traditional extensive economic growth
 381 to intensive, more efficient economic growth. However, lower efficiency values are found in
 382 Northeast and Southwest China, where related countermeasures and suggestions should be proposed
 383 to enable suitable improvements in the future.

384 **Table 9 Regional CCR and PCE Efficiency Values of the Construction Industry in 2016**

Number	Area	Province	Efficiency of the CCR model	Rank	Efficiency of the PCE model	Rank
1	East China	Shanghai, Jiangsu, Zhejiang, Anhui, Fujian, Jiangxi, Shandong	0.949	2	0.751	1
2	South-Central China	Henan, Hubei, Hunan, Guangdong, Guangxi, Hainan	0.970	1	0.728	2
3	North China	Beijing, Tianjin, Hebei, Shanxi, Inner Mongolia	0.894	3	0.670	3
4	Northeast China	Liaoning, Jilin, Heilongjiang	0.849	5	0.626	6
5	Southwest China	Sichuan, Chongqing, Yunnan, Guizhou	0.820	6	0.650	4
6	Northwest China	Xinjiang, Qinghai, Gansu, Ningxia, Shaanxi	0.874	4	0.648	5

386
387
388

389 4.4 Sensitivity Analysis

390 Sensitivity analysis is to evaluate the influence of one parameter (independent variable) on the
391 value of another parameter (dependent variable) from the perspective of quantitative analysis. In this
392 part, a discussion is provided on how the GTFP of the construction industry was affected by the
393 decision maker's optimism about the digital transformation prospect of the construction industry
394 (that is, parameters α , β , θ , and λ).

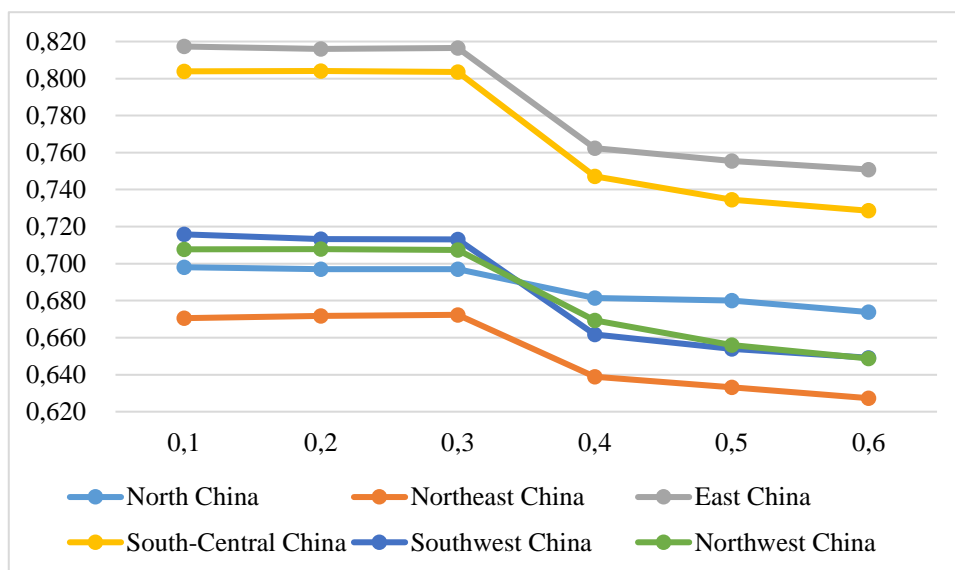

395 The efficiency values of the regional construction industry when parameter λ is set with
396 different values, such as 0, 0.2, 0.4, 0.6, 0.8, and 1, are calculated (see Table 9 for the detailed results).

397 **Table 10 Efficiency Value of the Regional Construction Industry with Different λ Values**

Area	$\lambda=0$		$\lambda=0.2$		$\lambda=0.4$		$\lambda=0.6$		$\lambda=0.8$		$\lambda=1$	
	Result	Rank	Result	Rank	Result	Rank	Result	Rank	Result	Rank	Result	Rank
East China	0.789	1	0.753	1	0.753	1	0.751	1	0.747	1	0.749	1
South-Central China	0.774	2	0.738	2	0.736	2	0.728	2	0.727	2	0.732	2
North China	0.672	5	0.666	3	0.666	3	0.671	3	0.670	3	0.677	3
Northeast China	0.647	6	0.627	6	0.625	6	0.626	6	0.623	6	0.313	6
Southwest China	0.680	3	0.649	5	0.650	5	0.650	4	0.647	4	0.504	5
Northwest China	0.673	4	0.653	4	0.652	4	0.648	5	0.645	5	0.652	4

398 When λ is assigned values of 0, 0.2, and 0.4, the decision maker is optimistic about the prospect
 399 of digital transformation in the construction industry. However, when the values are 0.6, 0.8 and 1,
 400 the decision maker is pessimistic about this prospect. According to Table 9, when λ is set with
 401 different values, the efficiency value in each region also changes accordingly, but there are no
 402 significant changes as a whole. Regardless of the value assigned to λ , East China and South-Central
 403 China are always the regions with the most effective efficiency values. The region with the lowest
 404 value is Northeast China, and slight changes are also found in North, Southwest and Northwest China.

405 This study, by changing the values representing optimistic and pessimistic attitudes (that is,
 406 parameters α , β , and θ) towards the prospect of the digital transformation of the construction industry,
 407 explored how the different attitudes of the decision maker affected the efficiency value of the
 408 regional construction industry. Here, the original values of α , β and θ were assumed to be 0.5, 0.3,
 409 and 3, respectively. Consequently, Figs. 3, 4, and 5 show the impact of changed parameters α , β and
 410 θ on the efficiency value, respectively.

411
 412 **Fig. 5 Influence of α on the Efficiency Values of the Regional Construction Industry**

413 Fig. 5 shows the change in efficiency value when the degree of the decision maker's optimism
 414 about digital transformation of the construction industry (parameter α) is changed. The value of
 415 parameter α is set to 0.1-0.6. As shown in the figure, the higher the value of α is, the more optimistic
 416 the decision maker is about the digital transformation of the construction industry. However, analysis
 417 indicates that with the continuous increase in α , the overall efficiency of the construction industry in
 418 various regions changes steadily first and then declines. Fig. 5 identifies that although the decision
 419 maker is more optimistic about digital transformation, this optimism fails to improve the GTFP of
 420 the entire construction industry.

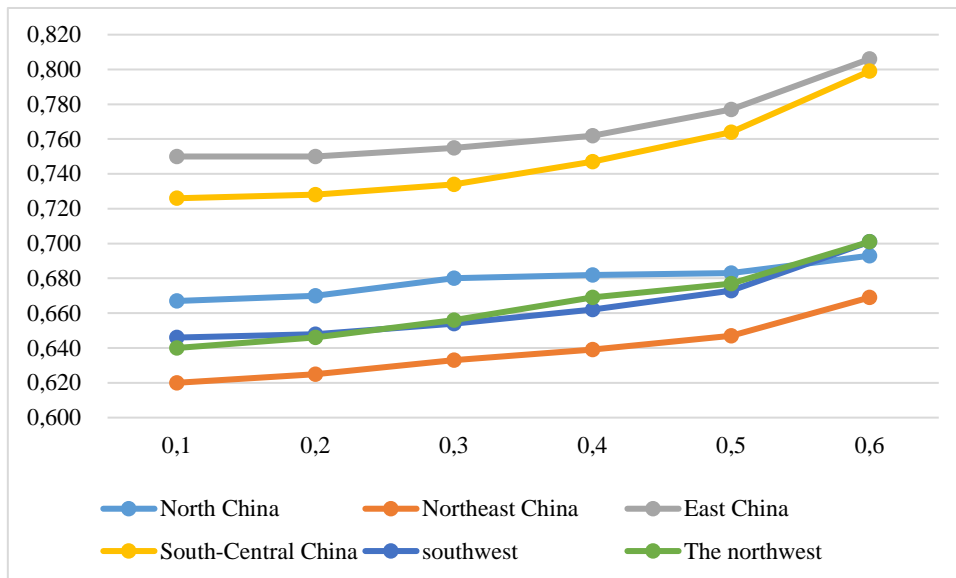

Fig. 6 Influence of β on the Efficiency Values of the Regional Construction Industry

421
422

423 Fig. 6 shows the change in efficiency value when the degree of the decision maker's pessimism
 424 about digital transformation of the construction industry (parameter β) is changed. The value of
 425 parameter β is set to 0.1-0.6. As shown in Fig. 6, the higher the value of β is, the more pessimistic
 426 the decision maker is about the digital transformation of the construction industry. However, analysis
 427 indicates that with the continuous increase in β , the overall efficiency of the construction industry in
 428 various regions changes steadily first and then rises. Fig. 6 shows that although the decision maker
 429 is more pessimistic about digital transformation, this pessimism improves the GTFP of the entire
 430 construction industry to some extent.

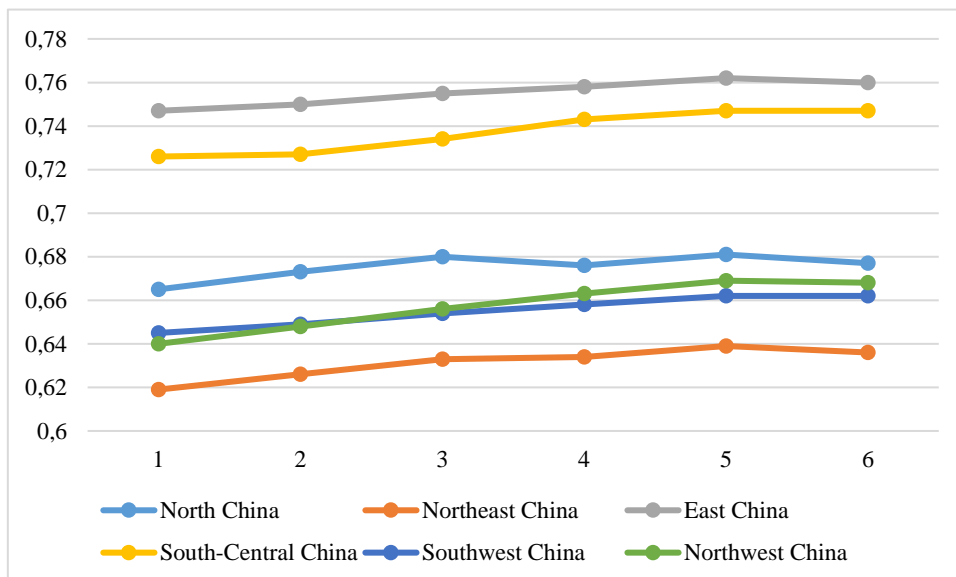

Fig. 7 Influence of θ on the Efficiency Values of the Regional Construction Industry

431
432

433 Parameter θ indicates the degree of the decision maker's pessimism about digital transformation.
 434 Specifically, a larger value signifies that the construction industry suffers from greater loss during
 435 digital transformation. Fig. 7 shows the change in the regional efficiency value when parameter θ is

436 changed, with θ set between 1 and 6. As shown in Fig. 7, the higher the value of θ is, the more
437 optimistic the decision maker is about digital transformation of the construction industry. However,
438 analysis indicates that with the continuous increase in θ , the overall efficiency rises steadily. In other
439 words, Fig. 7 shows that although the decision maker is more pessimistic about digital transformation,
440 this pessimism improves the GTFP of the entire construction industry to some extent.

441 The appeal shows that the decision maker is increasingly optimistic about the digital
442 transformation of the construction industry (parameter α), but the GTFP of the construction industry
443 has not improved. Further, the decision maker is increasingly less optimistic about the digital
444 transformation of the construction industry (parameters β and θ), and the GTFP of the construction
445 industry has been improved to some extent.

446 **5 Discussion**

447 The research and analysis in this paper provides a new perspective on the relationship between
448 regional differences in the construction industry, the preference of decision makers for digital
449 transformation and Total factor productivity in the context of digital transformation, this paper fills
450 the blank of the research on the digital transformation prospect of the construction industry, and
451 makes an empirical study on whether the digital transformation can bring more benefits to the
452 construction industry.

453 According to the results of PCE model and CCR model, there are obvious differences between
454 regions in the green Total factor productivity of construction industry. The results are consistent with
455 those of Xiang Pengcheng et al [45]. The regional differences of China's construction industry show
456 that the GTFP values are higher in the east, north, south-central and south-west, while the GTFP
457 values are lower in the northeast and northwest, the difference of digital transformation degree
458 between different regions is verified; Feng Yahong et al [46] believe that there are also regional
459 differences in the transformation rate of green economy in the construction industry. The green
460 economy output benefit of the construction industry in Eastern and central China is far higher than
461 that in Western and northeastern China, showing a trend of polarization, behind the trend of
462 polarization, there is a tendency for the inter-regional output benefit to shrink, which may be due to
463 the implementation of our overall regional development strategy, the "Belt and Road", the
464 coordinated development of Beijing, Tianjin and Hebei, the Yangtze River Economic Belt and other
465 new national-level regional development strategies have narrowed the regional economic gap and
466 promoted the digital transformation of the construction industry, increased Green Total factor
467 productivity in regional construction; Zhou Yong et al [47] believe that the GTFP in various regions
468 of China is on the rise, and that the growth rate in the Eastern Region is obviously higher than that

469 in the western and northeastern regions, showing an imbalance in the region, fan Jianshuang et al
470 [48] think there are some differences in the growth of TFP in the regional construction industry.
471 Generally speaking, the growth of TFP in the construction industry is slow, the growth of
472 Midwestern Sectional Figure Skating Championships is low, and the growth of TFP in the eastern
473 region is high, the coupling degree distribution of TFP growth and regional economic growth
474 basically conforms to the law of spatial differentiation in the East, middle and West, which is closely
475 related to the economic situation at that time, but in recent years, with the implementation of the
476 strategy of national rejuvenation of Central Plain, the proposal of the regional development strategy
477 of the Yangtze River Economic Belt makes the central region grow rapidly, which also drives the
478 development of the construction industry and makes the central region's TFP grow rapidly.

479 In the context of digital transformation, the change of GTFP in the construction industry is also
480 closely related to the attitude of decision makers towards digital transformation, the study is a ground
481 breaking analysis of how decision makers' expectations of the digital transformation of the
482 construction industry affect Total factor productivity. The results show that policymakers are
483 increasingly optimistic about the digital transformation of the construction industry, but the
484 construction industry's GTFP has not improved. In addition, the digital transformation of the
485 construction industry is becoming less and less favored by policy makers, and the GTFP of the
486 construction industry has been improved to a certain extent.

487 **6 Conclusions**

488 At present, it is the initial stage of construction industry digital transformation. Due to the
489 phenomenon of high investment cost in digital transformation, the input-output ratio of China's
490 construction industry digital transformation is not high in the short term, and the impact of digital
491 transformation on green total factor productivity of construction industry is not obvious, so it fails
492 to improve the growth of green total factor productivity of construction industry in the short term.
493 This study provides some practical implications for managers and policy makers to better understand
494 the impact of digitization on the construction industry. Based on the above analysis, the following
495 policy suggestions are proposed:

496 (1) Chinese manufacturing managers should fully understand and accept the positive impact of
497 digital transformation on the construction industry. Digital transformation, as a means to transform
498 the green development of the construction industry, will improve the green total factor productivity
499 of the construction industry to a certain extent. Through the use of digital technology and application,
500 managers should constantly improve the level of building product planning and design, create green
501 building construction standards, so as to improve the quality of building products.

502 (2) On the one hand, Chinese policy makers should formulate differentiated policies based on
503 the actual regional development situation to stimulate the growth of GTFP in construction industry.

504 Especially in the northeast and northwest regions, the government should guide the industry to
505 improve the GTFP by means of economic stimulus or financial support. On the other hand, Chinese
506 policymakers should pay attention to high-quality development in the digital transformation of the
507 construction industry. They should focus on the digital technological innovation of construction
508 industry, formulate and issue relevant fiscal policies, laws, standards and evaluation systems, so as
509 to form a good environment for digital innovation of construction industry in the whole society, and
510 improve the input-output ratio of digital transformation of construction industry in this way.

511 This study has some limitations. First, the research on green total factor productivity under the
512 prospect of digital transformation is limited to the construction industry and has not been extended
513 to other industries. Second, sample data of construction industry in different countries or regions
514 should be included and compared with China's data, so as to fully understand the development of
515 green total factor productivity under the prospect of digital transformation.
