García Sanjuan, F.; Jaén Martínez, FJ.; Catalá Bolós, A. (2015). Multi-Display Environments to Foster Emotional Intelligence in Hospitalized Children. ACM.
ABSTRACT
Long-term and frequent hospitalized children are under high loads of emotional stress, which affects their well-being in addition to the illness they are suffering. This thesis proposes and will focus on an approach to use Multi-Display Environments (MDE) in pediatric hospitalization contexts to improve patients’ emotional intelligence so they can deal with the negative emotions produced by their situation.

Categories and Subject Descriptors
H.5.2, H.5.3 [Information Interfaces and Presentation (e.g., HCI)]: User Interfaces – Input devices and strategies, interaction styles. Group and Organization Interfaces – Computer-supported cooperative work.

General Terms
Design, Experimentation, Human Factors, Standardization

Keywords
Multi-Display Environments (MDE), Hospitalization, Emotional Intelligence, Child-Computer Interaction, Socialization

1. INTRODUCTION
According to hospital morbidity statistics from INE for 2013, the number of pediatric hospital stays in 2012 in Spain amounted to 1,813,009. Besides the fears associated to their illness, frequent and long periods of hospitalization provoke on children high loads of emotional stress and insecurity for being away from their home and their comfort zone with parents and friends. To tackle these problems, there are previous studies that demonstrate that play activities allow children to face the anxiety, conflicts, and fear caused by hospital experiences [4]. However, the application of new technologies in the context of hospital schools has been limited mostly to scenarios of individual use in which emotional stress is addressed in a simplistic way by using technologies to enable communication channels between children and their homes or external schools. However, we not only aim at deviating the children’s attention from the clinical processes they are subject to, but also at facilitating the emotions that help them accept their new medical situation and adapt their mental state to face the issues that could arise by means of collaborative game activities.

Since emotional intelligence is mainly of social nature, traditional desktop computers are not the best option to support its training because these devices are mostly designed for individual use. On the other hand, digital tabletops have been shown to be very suitable tools for use in collaborative environments (e.g., [3]). Their multi-touch capabilities allow simultaneous interaction, which contributes to a more democratized participation [9] and a better workspace awareness, since face-to-face settings allow users to know what the others are doing.

Despite research showing these advantages, it is rare to see tabletops embedded in real settings. This is due to a number of disadvantages: their high cost; their limited workspace dimensions, which can only accommodate a certain number of participants; and the fact that their form factor complicates mobility. Therefore, this work will address the development of a collaborative play environment based on multiple interactive surfaces to support the learning of emotional intelligence in pediatric hospitalization contexts aimed at reducing the negative emotional impact caused by long-term or frequent hospital stays.

2. RELATED WORK
2.1 Emotional Intelligence and Tabletops
Several previous works have considered technology as a way of acquiring emotional intelligence abilities. Morris et al. [6], for example, involve several users collectively around big interactive surfaces in an emotional identification task, through the tagging of different images according to the emotions they cause. During the course of the activity, the researchers observe the users speaking with one another about their feelings towards the images, and, before tagging an image, they self-reflect and ask themselves questions like: “Am I happy?”, “Am I sad?” According to the authors, their explorations show people’s desire of having technologies that allow the complex expression of emotions through a game experience. However, most of previous works in this area target adults or adolescents, and the activities performed aim mainly at identification of emotions, whereas the practical use of those emotions to solve problems has not yet been fully explored.

Others target children with autistic spectrum disorders (ASD) to increase socialization through technology. As an example, Gal et al. [1] make use of an interactive tabletop to perform storytelling activities to foster collaboration among kids with ASD. They observe an increment of the number of approaches between the children, a higher load of positive affect as well as a higher tendency to express emotions. These type of works, however, are not aimed at making these children reason about their emotions in a way they can overcome an unfavorable personal situation and they rely on interactive tabletops, which may be complex to implant in real hospital environments, as stated previously.

2.2 Multi-Display Environments (MDE)
MDE have been object of much previous research. Traditionally, their main purpose was enlarging the visualization space via the physical union of several smaller screens (e.g. [8]), and the interaction played a more secondary role, therefore leading to mono-user environments with difficulties to favor collaboration, which is fundamental in emotional learning. Besides, the configurations tended to be static (i.e., the number of screens was fixed a priori),
and to not allow the mobility of the participants. The posterior
popularization of mobile devices, such as phones and PDAs, in-
troduced a higher degree of mobility and multuser (parallel) in-
teraction since each user could interact with their own device,
which they carried with them. Mandryk et al. [5] study the im-
pressions of teenagers when using PDAs in a collaborative game.
Because of the reduced dimensions of these devices, the research-
ers encouraged them to enlarge the visualization space by joining
the screens. The participants, however, reported low sense of lib-
erty of movements because they had to maintain the devices to-
gether during the course of the activity. Therefore, the mobility
was achieved in detriment of the visualization space. This prob-
lematic is due to the fact that the approaches commented so far
rely basically on joining smaller screens to form a bigger one
(and, therefore, rectangular). In this respect, some existing works
have proposed alternatives. For instance, Pinch [7] is a technique
to couple smartphones and tablets via a manual gesture, and it
supports free-form topologies and dynamic modification of the
device group to the extent of not needing the displays to be physi-
cally joint once coupled. A limitation of this work, however, is
that the resulting topology is still flat and the only interaction
technique supported is touch. As this analysis suggests, previous
research on MDE has mainly focused on technical aspects, and
their capabilities have not yet been proven in real settings but
rather in experimental contexts in order to show the performance
of a given approach. This implicates that, in their design, the uti-
mate activity to be performed by the users with these MDE has
not been considered deeply enough. In our context, the software
system and underlying interaction techniques will be considered
effective not only if the children are able to perform quickly the
manipulations and they understand how to make them, but also if
the system supports effectively the construction of experiences
that develop emotional intelligence through games.

3. RESEARCH OBJECTIVES
From previous works’ limitations, we have identified several
technical dimensions that will be addressed in our work in order
to successfully build collaborative MDE for children in hospital-
ized environments. These are classified into dimensions regard-
ing the construction of the environment and interaction require-
ments. With respect to the former, our approach will allow several
displays to form a common environment of any topology, not neces-
sarily the traditional rectangular one, and possibly discontinuous
to remove the need for the devices to be physically joint. This
way, the users will be able to choose more freely their location.
The number of devices will be unbounded, and their annexation to
one another will be done in a transparent way in order to avoid
complex registration methods. Concretely, our approach to ad-
dress these requirements will rely on using the built-in camera of
tables and smartphones to track their own position with respect to
a wallpaper situated on the ceiling using computer vision algo-
rithms, allowing the system to build a logical map of all the tab-
lets in the group. Since the only requirement is having the wallpa-
er/marker partially in sight, this approach can also allow some
3D topologies by simply placing the displays in different planes.
Regarding the interactions that our MDE will allow, the most
basic one, in order to benefit from the advantages of tabletops in
terms of collaboration, is to consider all displays as part of a
whole, public surface, and therefore to permit many users interact
with the same display at the same time, and also a given user to
interact with many devices at once. In order to achieve more dy-
namic scenarios users will be able to modify the resulting surface
by moving the displays through the environment during the course
of the collaboration. And, in order to obtain richer ways of inter-
action, our proposal will support interacting with alternative me-
dia such as tangibles, which can result more intuitive for children
as they can grab and manipulate actual physical objects. Moreo-
ver, it will also accept aerial interactions using gestures with fin-
gers or dedicated objects with the purpose of avoiding interfer-
ence with another user’s actions.

In sum, our goal is to design activities to foster emotional intel-
ligence in hospitalized children. Since this type of intelligence is
mainly social, we propose to build collaborative environments
using several affordable surfaces such as tablets and smartphones.
The dimensions identified previously will then be explored be-
yond their technical aspects regarding how they impact collabora-
tion among the children and how they foster emotional intelli-
gence that might help them overcome the stressful situations they
experience during their hospitalization.

4. ACKNOWLEDGEMENTS
This work is supported by Spanish MINECO (TIN2010-20488
and TIN2014-60077-R), from Universitat Politècnica de València
(UPV-FE-2014-24), and from GVA (APOSTD/2013/013 and
ACIF/2014/214).
