**Abstract.** Niobium phosphate (NbPO<sub>4</sub>) was used as a heterogeneous catalyst in the protection of a series of aliphatic alcohols as tetrahydropyranyl (THP) derivatives. Protection of primary alcohols using this material with strong Brønsted acid sites was achieved in good yields (75-94%), while moderate values were obtained in the protection of secondary and tertiary alcohols (50-84%), largely dependent on the steric hindrance in the proximity of the hydroxyl moiety. NbPO<sub>4</sub> also catalyzed deprotection of THP ethers derived from primary alcohols and phenol with moderate yields (65-99%).

## Introduction

Protecting groups are important tools in organic synthesis. In particular, dihydropyran (DHP) has been widely employed in the protection of alcohols and phenols to yield the corresponding THP ethers (Table 1),<sup>[1]-[2]</sup> especially due to the robust and unreactive nature of the resulting ethers under a variety of reaction conditions, notably towards strongly basic media, hydrides, acylating and alkylating agents.<sup>[3]</sup> Protection of alcohols and phenols with DHP has been widely examined in the past under a number of catalytic conditions, both homogeneous and heterogeneous. Homogenous catalysts, such as *p*-TsOH,<sup>[4]</sup> Bi(OTf)<sub>3</sub>•H<sub>2</sub>O,<sup>[3]</sup> CuCl<sub>2</sub><sup>[5]</sup> and *p*-toluenesulfonic acid,<sup>[6]</sup> have been reported. Heterogeneous-derived catalytic pathways have gained considerable attention due the advantageous ease of separation and catalyst reusability, as compared with their homogeneous counterparts. With regards to the THP protection of alcohols, catalysts such as Amberlyst-15,<sup>[7]</sup> natural Kaolinitic Clays,<sup>[8]</sup> sepiolite,<sup>[9]</sup> HY zeolites<sup>[10]</sup> and ZnCl<sub>2</sub> supported on alumina<sup>[11]</sup> have been successfully used. When considering the deprotection of THP-ethers both homogenous<sup>[3, 12]</sup> and heterogeneous<sup>[9, 13]</sup> approaches have also been used in the past.

Recently, NbPO<sub>4</sub> has been employed as an heterogeneous catalyst for the dehydration of fructose,<sup>[14]</sup> the esterification of fatty acids,<sup>[15]</sup> the oxidation of benzyl alcohols<sup>[16]</sup> and the benzylation of anisoles.<sup>[17]</sup> Due to its considerable Brønsted acidity ( $H_0 \sim -8.6$  to  $-5.6$ )<sup>[18]</sup> and its heterogeneous nature, NbPO<sub>4</sub> warrants investigation for protection-deprotection of alcohols.

Our interest in niobium compounds relates to the fact that this rare metal is produced almost exclusively by Canada and Brazil and used mostly as an additive to steel in order to modify its

mechanical properties.<sup>[19]</sup> We believe that applications in the field of catalysis hold the potential for better value-added uses of niobium and some of our recent contributions reflect this interest, as well as collaborative projects between Canada and Brazil.

Given these known properties and the benefits of heterogeneous catalysis, this contribution discusses the use of NbPO<sub>4</sub> as a catalyst in this important class of organic reactions, using THP as the primary protective group. To the best of our knowledge, this is the first time NbPO<sub>4</sub> has been employed as a catalyst for organic protection-deprotection chemistry.

## **Experimental**

*Materials and instrumentation.* Phenol (re-distilled 99%+), 1-pentanol (99%+), cinnamyl alcohol (98%), 3,4-dihydro-2H-pyran (DHP; 97%), phenethyl alcohol (99%), benzyl alcohol anhydrous (99.8%), 1-phenyl-1-propanol (≥97%), 2-phenyl-2-propanol (97%), 1-methylcyclohexanol (96%), *tert*-butanol (99.5%+), cyclohexanol (99%) and dimethyl sulfone (98%) were purchased from Sigma-Aldrich and used as received. NbPO<sub>4</sub> was generously provided by CBMM (Companhia Brasileira de Metalurgia e Mineração). ACS grade methanol and dichloromethane were purchased from Fisher Scientific and used as received. NMR spectra were recorded using a Bruker Avance 400 MHz in CDCl<sub>3</sub>.

*General procedure for the protection of alcohols with DHP.* To a solution of the alcohol (10 mmol) in dichloromethane (25 mL) 3,4-dihydro-2H-pyran (13 mmol, 1.3 equivalent) was added, followed by NbPO<sub>4</sub> (100 mg). The reaction was monitored using GC-MS and, upon completion, the catalyst was separated from the reaction mixture by centrifugation. The solvent and the excess DHP were removed from the reaction mixture by rotary evaporation. The purity

of the product was examined by  $^1\text{H}$  and  $^{13}\text{C}$  NMR. Compound **10** was purified by column chromatography [ $\text{SiO}_2$ : Hexanes/EtOAc (4:1)].

*General procedure for the deprotection of THP ethers.* To a solution of the THP ether (3 mmol) in refluxing MeOH (25 mL)  $\text{NbPO}_4$  (25 mg) and dimethyl sulfone (3.5 mmol) were added. The reaction was monitored by GC-MS and then the catalyst was separated from the reaction mixture by centrifugation. The solvent was eliminated under reduced pressure and the crude analyzed by  $^1\text{H}$  and  $^{13}\text{C}$  NMR using dimethyl sulfone as an internal standard.

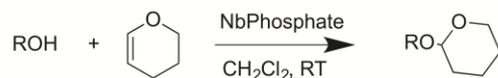

*Recyclability Experiments.* The recyclability of the  $\text{NbPO}_4$  catalyst was examined in both the DHP protection of benzyl alcohol and the corresponding THP deprotection. The initial protection and deprotection trials were carried out using the experimental procedures described above. Following the initial trial, the  $\text{NbPO}_4$  catalyst was recovered and washed with  $\text{CH}_2\text{Cl}_2$  for the DHP protection and  $\text{CH}_3\text{OH}$  for the THP deprotection. This procedure was repeated a total of four times to remove any adsorbed materials from the catalyst surface of the catalyst. After the final wash, the supernatant was decanted and the solid left to dry overnight. The recovered  $\text{NbPO}_4$  was weighted and the reagents scaled down to ensure a consistent substrate/catalyst ratio in subsequent reuse trials.

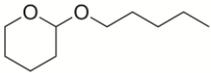

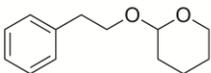

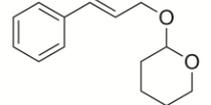

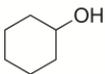

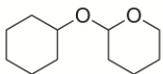

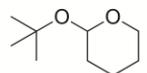

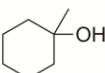

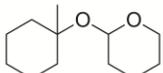

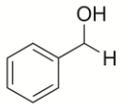

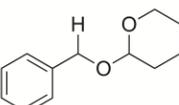

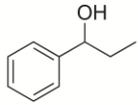

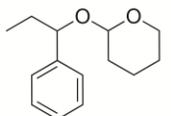

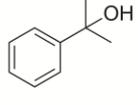

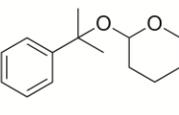

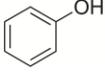

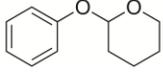

## **Results and Discussion**

The experimental procedure of the protection of alcohols is relatively straightforward.  $\text{NbPO}_4$  was added to a solution of the alcohol substrate and THP in dichloromethane, and the reaction mixture was stirred at room temperature and monitored by thin layer chromatography or GC-MS. The catalyst was then removed simply by centrifugation at 3000 rpm and the excess of DHP was eliminated under reduced pressure.

**Table 1.** NbPO<sub>4</sub>-catalyzed formation of THP ethers from a series of alcohol and phenol substrates.

Entry	Substrate	Product	Time	Yield
1			5 h	94% <sup>[a]</sup>
2			3 h	88% <sup>[a]</sup>
3			24 h	85% <sup>[a]</sup>
4			24 h	86% <sup>[a]</sup>
5			24 h	73% <sup>[a]</sup>
6			24 h	53% <sup>[b]</sup>
7			1 h	95% <sup>[a]</sup> 91% <sup>[a,c]</sup> 80% <sup>[a,d]</sup>
8			24 h	50% <sup>[b]</sup>
9			24 h	66% <sup>[b]</sup>
10			18 h	75% <sup>[a]</sup>

<sup>a</sup>Isolated yield. <sup>b</sup>Determined by <sup>1</sup>H NMR spectroscopy. <sup>c</sup>Reuse trial 1. <sup>d</sup>Reuse trial 2.

The isolated yields obtained for the formation of THP ethers from a series of organic alcohols are presented in Table 1. The yields obtained show a clear dependence on the steric hindrance suffered by the reactive -OH center. Specifically, protection of primary alcohols **1-3 and 7** afforded the highest isolated yields of the corresponding THP-ether, ranging from 85% to 94%. Accordingly, the yield of the protected product was found to decrease concomitantly with the substitution of the alcohol functionality. This trend is clearly observed when comparing the values obtained for a structurally comparable secondary and tertiary alcohol. Thus, the protection of cyclohexanol (**4**) and 1-methyl-cyclohexan-1-ol (**6**) illustrates a considerable decrease in the efficacy of the NbPO<sub>4</sub>-catalysed protection pathway (from 86% to 53%, respectively) with increasing substitution of the alcohol moiety. The same general trend was observed when comparing the yields for entries **7** and **8** where increased substitution of the alcohol translates into a 38% reduction in the yield of product obtained. The protection of these sterically hindered alcohols also required longer reaction times. Indeed, increased steric hindrance in close proximity to the OH functionality will partially inhibit its addition to the carbocation that is initially formed in the reaction upon the protonation of DHP in a similar fashion to the acid catalyzed hydration of alkenes. Interestingly, NbPO<sub>4</sub> has also been successfully employed in the THP protection of phenol (**6**) in 75% yield over moderate reaction times (18 hours) (see Table 1). The recyclability of the catalyst was determined by reusing the catalyst in two separate trials in the protection of benzyl alcohol. The initial isolated yield (95%) was found to decrease marginally to 91% after one reuse and to 80% after a second recyclability trial. After three reuses, the NbPO<sub>4</sub> catalyst still demonstrated considerable acidic activity, indicating that this heterogeneous material may be an economical and recyclable means of promoting DHP alcohol protections.

Methods used for the deprotection of THP ethers generally employ strongly acidified reaction media and long reaction times.<sup>[3]</sup> Therefore, a mild but efficient method to selectively deprotect THP ethers in the presence of other sensitive functional groups has yet to be achieved. To this end, NbPO<sub>4</sub> was investigated as a potential alternative to catalytically deprotect THP ethers and restore the corresponding alcohol by acidic hydrolysis based on its strong Brønsted acid nature using relatively mild reaction conditions. In fact, deprotection of THP ethers was achieved in good yields under stirring in refluxing methanol.

**Table 2.** NbPO<sub>4</sub>-catalyzed deprotection of THP ethers substrates.

Entry	Substrate	Product	Time	Yield <sup>[a]</sup>
11			1 h	99%
12			4 h	65%
13			1 h	91% 79% <sup>[b]</sup> 17% <sup>[c]</sup>
14			1.5 h	69%

<sup>a</sup>Yields obtained by NMR using dimethyl sulfone as internal standard <sup>b</sup>Reuse trial 1. <sup>c</sup>Reuse trial 2.

The results obtained for the deprotection of THP ethers **11-14** are presented in Table 2. The yield for deprotection of THP ethers formed from primary alcohols (entries **11-12**) resulted in large alcohol yields (65% to 99%). Compound **14** was also successfully deprotected to phenol using NbPO<sub>4</sub> with a yield of 69% in 1.5 hours. Importantly, NbPO<sub>4</sub> catalyzed protection is better, both in temperature and time, when compared to previous deprotection studies using Bi(OTf)<sub>3</sub>•H<sub>2</sub>O as a homogeneous catalyst.<sup>[3]</sup> As was examined with the DHP protection experiments, the reusability of NbPO<sub>4</sub> in THP deprotection was also examined. The initial yield in the NbPO<sub>4</sub>-initiated deprotection of THP benzyl alcohol was 91%. This yield decreased to 79% after only one reuse and further diminished to a mere 17% after a second trial. These results suggest that NbPO<sub>4</sub> is not as efficiently recycled in THP deprotection process.

NbPO<sub>4</sub> holds a clear advantage to other catalysts that have been employed in both DHP protection and THP deprotection studies. Recyclability experiments using NbPO<sub>4</sub> clearly demonstrate that the heterogeneous nature of the niobium-derived catalyst allows for the recovery and reuse of the material in several subsequent trials, lending to increased economic advantage of this material as compared to the traditional homogeneous catalysts.<sup>[2, 4-6]</sup> Comparison with other heterogeneous catalysts is difficult, as yields are comparable between NbPO<sub>4</sub> and these alternatives. However, literature precedents using other heterogeneous supports have lacked study on the recyclability of these materials.<sup>[8-11]</sup> Given NbPO<sub>4</sub> is a very much a Canadian resource, the development and application of this material within common, catalytically induced organic transformations is important for both economic and environmental sustainability.

## Conclusion

The protection and deprotection of alcohols using tetrahydropyranyl (THP) derivatives was performed using  $\text{NbPO}_4$  as catalyst. It was shown that the protection of alcohol was obtained in high yield especially in the case of primary alcohols reflecting the reduced steric hindrance as compared to secondary and tertiary alcohols. It was also shown that phenol could be protected using the same protocol. The deprotection of primary alcohols and phenol also showed high yields. Finally, exceptional recyclability of the  $\text{NbPO}_4$  catalyst in benzyl alcohol DHP protection trials, followed by moderate reusability in THP deprotection demonstrates the robust and sustainable acid catalytic nature of this abundant Canadian resource.
