## Abstract

Laboratory continuous regime equipment was designed and built for supercritical CO<sub>2</sub> microbial inactivation assisted by high power ultrasound (SC-CO<sub>2</sub>-HPU). Apple juice, previously inoculated with 1-10x10<sup>7</sup> CFU/ml of *Saccharomyces cerevisiae*, was treated in the equipment at different juice residence times (3.06-9.2 min), temperatures (31-41 °C) and pressures (100-300 bars). Inactivation ratios were fitted to a hybrid (boolean-real) model in order to study the effect of the process variables. The maximum inactivation achieved by the system was 7.8 log-cycles. The hybrid model demonstrated that HPU has a significant effect on inactivation after shorter residence times. A multi-objective optimization performed with the hybrid model showed that 6.8 log cycles of inactivation could be obtained after a minimum residence time (3.1 min) with HPU application, whereas under the same conditions but without HPU, the inactivation would be 4.3 log-cycles. Therefore, the ultrasound assisted continuous system has shown a great potential for microbial inactivation using SC-CO<sub>2</sub> under mild process conditions.

**Keywords:** Non-thermal process; supercritical CO<sub>2</sub>; ultrasound; continuous regime; *S. cerevisiae* inactivation.

56

## 57 **1. Introduction**

58 Non-thermal food preservation techniques, such as pulsed light (Ramos-Villarroel et  
59 al., 2012, Maffei et al., 2014), ozone (Patil et al., 2010; Torlak, 2014), high hydrostatic  
60 pressure (Buzrul, 2014; Baptista et al., 2015), pulsed electric fields (Boulaabaa et al.,  
61 2014; Raso et al., 2014), ultrasound (Gabriel, 2014; **Khandpur and Gogate, 2016**) or  
62 ultraviolet radiation (Baysal et al., 2013; Gabriel et al., 2015) have been developed in  
63 response to an increasing consumer demand for natural, fresh food which is free from  
64 chemical preservatives. These non-thermal technologies have demonstrated their  
65 capacity to preserve nutrients and functionality in food, extending its shelf-life and  
66 minimizing the changes in natural color, taste, flavor and texture. One of these  
67 technologies, supercritical carbon dioxide (SC-CO<sub>2</sub>) processing, has been applied in  
68 the inactivation of enzymes and both pathogen and spoilage microorganisms (Choi et  
69 al., 2008). SC-CO<sub>2</sub> treatment involves food contact with SC-CO<sub>2</sub> for a certain period of  
70 time in a batch, semi-batch or continuous equipment.

71 SC-CO<sub>2</sub> treatments have been applied to inactivate gram-negative bacteria, such as  
72 ***Salmonella enterica serovar Typhimurium***, *Escherichia coli* or *Yersinia enterocolitica*,  
73 and gram-positive bacteria or yeast, such as *Listeria innocua*, *Listeria monocytogenes*  
74 or *Saccharomyces cerevisiae* (Bermúdez- Aguirre and Corradini, 2012; Garcia-  
75 González et al., 2007). The studies dealing with inactivation techniques including SC-  
76 CO<sub>2</sub>, have demonstrated that gram-positive cells are more resistant than gram-  
77 negative ones owing to the fact that their cell wall is thicker (Villas-Boas et al., 2006).  
78 Ortuño et al. (2012**b** and 2013) showed that when using SC-CO<sub>2</sub> under 225 bar and 36  
79 °C, 50 min were necessary to reach a reduction of 7 log-cycles of *E. coli*, compared to  
80 the 150 min needed to reach a 3 log-cycle reduction for *S. cerevisiae*, under the same  
81 process conditions. These results support the connection between the wall thickness  
82 and the resistance to SC-CO<sub>2</sub> inactivation. **In addition to the wall thickness, the cell wall**  
83 **composition and the expression of stress-response genes, such as the heat shock**

84 proteins, are factors that determine the resistance of microorganisms to the process  
85 conditions (Ortuño et al., 2012a).

86 Most of the studies found in the literature use batch SC-CO<sub>2</sub> systems to inactivate  
87 microorganisms in liquid media. In order to obtain the required lethality after shorter  
88 processing times or when using a lower treatment intensity and to accelerate the CO<sub>2</sub>  
89 inactivation mechanisms in batch systems, previous studies analyzed the advantages  
90 of coupling SC-CO<sub>2</sub> with high power ultrasound (SC-CO<sub>2</sub>-HPU) for microbial  
91 inactivation purposes (Ortuño et al., 2012b; Ortuño et al., 2013; Spilimbergo et al.,  
92 2014). Ortuño et al. (2012b) showed that the SC-CO<sub>2</sub>-HPU treatment drastically  
93 reduced the time required for *E. coli* inactivation in LB broth with respect to SC-CO<sub>2</sub>  
94 processing; at 225 bar and 36 °C, an inactivation of 7 log-cycles was obtained in 2 min,  
95 instead of the 50 min required using only SC-CO<sub>2</sub>. In the case of *S. cerevisiae*  
96 inoculated in YPD broth, Ortuño et al. (2013) showed that 7 log-cycles of inactivation  
97 were achieved after 2 minutes of SC-CO<sub>2</sub>-HPU at 225 bar and 36 °C, while no  
98 inactivation was reached using only SC-CO<sub>2</sub>. Therefore, with this system (batch SC-  
99 CO<sub>2</sub>-HPU), an increase in the solubilization rate of SC-CO<sub>2</sub> in the liquid is produced, as  
100 well as an enhancement in the mass transfer of the SC-CO<sub>2</sub> into the microbial cells,  
101 due to the vigorous stirring produced by the ultrasonic field. Also cavitation can  
102 damage the microbial cell walls causing the loss of intracellular vital components.

103 In order to improve the efficiency of batch SC-CO<sub>2</sub> treatments, continuous systems  
104 have been developed. Several authors have studied the effect of continuous SC-CO<sub>2</sub>  
105 systems on the inactivation of different microorganisms (*E. coli*, *Lactobacillus*  
106 *plantarum*, *L. monocytogenes*, aerobic plate count, *S. enterica* serovar Typhimurium  
107 and *S. cerevisiae*), using different mediums (orange juice, carrot juice, watermelon  
108 juice, coconut water, beer) (Kincal et al., 2005; Gunes et al., 2005; Dagan et al., 2006;  
109 Damar et al., 2009; Fabroni et al., 2010; Zhenghui et al., 2011). These authors  
110 concluded that continuous systems require much shorter inactivation times compared  
111 with batch ones, due to the improvement in the CO<sub>2</sub> mass transfer produced by the

112 agitation, which permits both a quick saturation of CO<sub>2</sub> into the medium and the  
113 acceleration of the inactivation mechanisms. However, no work has been found in the  
114 literature combining a continuous SC-CO<sub>2</sub> system with the use of HPU.

115 Therefore, considering the effect of SC-CO<sub>2</sub>-HPU on the microbial inactivation and  
116 the productivity increase of the continuous regime processes, continuous regime SC-  
117 CO<sub>2</sub>-HPU laboratory equipment was designed and built. The aim of this paper was to  
118 study the effect of pressure, temperature and product residence time on yeast  
119 inactivation using the continuous flow SC-CO<sub>2</sub>-HPU system constructed for this  
120 application and to model and optimize the process operation.

121

122

## 123 **2. Materials and methods**

124

### 125 *2.1. Microbial preparation*

126 The microbial strain used in this study was *Saccharomyces cerevisiae* T73 (*S.*  
127 *cerevisiae*). It is a natural strain isolated from wine fermentation in Alicante (Spain)  
128 (Querol, Barrio, & Ramon, 1992), and it is commercialized as Lalvin T73 (Lallemand  
129 Inc., Montreal, Canada).

130

### 131 *2.2. Sample preparation and growth conditions*

132 A single colony of *Saccharomyces cerevisiae* T73 was inoculated in Yeast Peptone  
133 Dextrose Broth (YPD Broth, Sigma-Aldrich, USA) and grown overnight at 30 °C, using  
134 an incubation chamber (J.P. SELECTA, Model 3000957, Barcelona, Spain) and an  
135 orbital shaker at 120 rpm (J.P. SELECTA, Rotabit Model 3000974, Barcelona, Spain).  
136 For each experiment, a subculture was prepared by inoculating 100 µL from the starter  
137 in 100 mL of sterilized medium and incubated at 30 °C for 24 h to obtain cells in the  
138 stationary phase. Growth curves were determined in advance by both plating and the  
139 measurement of absorbance at 625 nm (data not shown). The culture was inoculated

140 in 1 liter of pasteurized commercial apple juice (Apple juice, Hacendado, Spain), to a  
141 cell concentration of  $1-10 \times 10^7$  CFU/mL and then the juice was immediately subjected to  
142 the treatment.

143

### 144 *2.3. Supercritical fluid processing*

145 A continuous **SC-CO<sub>2</sub>+HPU** equipment was designed as a continuous stirred tank  
146 reactor (CSTR) in which the HPU probe was submerged in the liquid phase (product),  
147 followed by a holding tube designed to increase the contact time between the product  
148 and the SC-CO<sub>2</sub>, analog to a plug flow reactor (PFR). The plant also included a pump  
149 for the CO<sub>2</sub> and another for the juice, a separation vessel and different auxiliary  
150 elements depicted in Fig. 1.

151 The volume of the liquid phase during the experiments in the sonication vessel was  
152 40 mL. The holding tube, analog to a PFR, had a volume of 52 mL. The HPU system  
153 (9-12, Fig. 1) has been patented (Benedito et al., 2011) in conjunction with the  
154 inactivation procedure and consists of a high power piezoelectric transducer, an  
155 insulation system and a power generator unit. The transducer ( $>1$  W/cm<sup>2</sup>) was inserted  
156 inside the inactivation vessel and included two commercial ring-shaped ceramics (11,  
157 Fig. 1; 35 mm external diameter; 12.5 mm internal diameter; 5 mm thickness;  
158 resonance frequency of 30 kHz) and a sonotrode (9, Fig. 1), which was specially built  
159 to concentrate the highest amount of acoustic energy on the application point. The  
160 sonotrode was powered with constant energy by the power generator unit (12, Fig. 1)  
161 during the SC-CO<sub>2</sub> process.

162 The SC-CO<sub>2</sub>-HPU process applied to the juice was as follows: first, liquid carbon  
163 dioxide was supplied from the bottom of the chiller reservoir (which stores it at  $-18$  °C)  
164 to the pump where it was compressed at the targeted pressure. For start-up, the  
165 equipment was stabilized at the treatment pressure ( $P$ ) and temperature ( $T$ ) only with  
166 SC-CO<sub>2</sub> at a constant flow rate of 5 mL/min. Thereafter, the ultrasound equipment was  
167 connected, and once the process conditions ( $P, T$ ) were fulfilled, the sample to be

168 treated was pumped to the mixing point (7, Fig.1) where it mixed with the SC-CO<sub>2</sub>. The  
169 mixture went into the sonication vessel (8, Fig. 1), where the HPU was applied. For the  
170 experiments with HPU, the power applied during the whole experiment was 40 W±5W  
171 (I=250 ±10mA; U=220 ±5 V, measured with a Digital Power Meter, Yokogawa, Model  
172 WT210) and the frequency 30.7±1.8 kHz. Pressure and temperature were kept  
173 constant during the experiment. The mixture of juice/SC-CO<sub>2</sub> exiting the treatment  
174 vessel went into the holding tube (14, Fig. 1) and, finally, into the separation vessel (15,  
175 Fig. 1). Prior to each experiment, the different sections of the equipment which the  
176 product flows through were cleaned and sanitized with disinfectant solution (Delladet  
177 VS2, Diversey, Spain), and distilled and autoclaved water. For each process condition,  
178 3 treated juice samples (3 mL) were extracted in sterile plastic test tubes at different  
179 times (4 min time interval) through the sonication vessel output (18, Fig. 1) and another  
180 3 samples through the separation vessel output (19, Fig. 1). The first sample was taken  
181 after 125 mL of juice was treated, to ensure the steady state was reached. The  
182 microbial analyses were performed on the three samples and averaged for each  
183 process condition. Sampling output tubes were cleaned and disinfected with 3 mL  
184 ethanol (96%v/v) after every sample extraction.

185

#### 186 2.4. Enumeration of viable microorganisms

187 The viability of *S. cerevisiae* in the samples was determined by the plate count  
188 method before and after every treatment. Samples were serially diluted and 100 µL of  
189 the appropriate dilutions were plated on Yeast Peptone Dextrose Agar (YPD Agar,  
190 Sigma-Aldrich, USA) in triplicate. The plates were incubated at 30 °C for 24 h before  
191 counting. The experimental results shown are the arithmetic mean and the standard  
192 deviation of  $-\ln(N/N_0)$  for at least three plates, where  $N_0$  is the initial number of cells in  
193 the control sample and  $N$  is the number of cells in the sample after the different  
194 treatment times.

195

196 2.5. Experimental design

197 Four process variables were considered: pressure ( $P$ ), temperature ( $T$ ), juice flow (  
198  $q$ ) and type of treatment (with or without HPU); keeping the SC-CO<sub>2</sub> flow ( $q_{CO_2}$ )  
199 constant at 5 mL/min. Initially, the effect of juice flow and pressure was studied in a 3x3  
200 complete factorial design at constant temperature. The product flow levels were 5, 15  
201 and 25 mL/min and the pressures were 100, 200 and 300 bar; every treatment was  
202 carried out at a temperature of 31 °C. In order to limit the SC-CO<sub>2</sub> consumption, the  
203 ratio between the SC-CO<sub>2</sub> and juice flows was limited to 1. The effect of temperature  
204 was studied from a 3x2x2 complete factorial design. The temperatures were 31, 36,  
205 and 41 °C, the pressures 100 and 200 bar, and there were 15 and 25 mL/min of  
206 product flow. All of the treatments were carried out with and without ultrasound and  
207 were run in triplicate. Taking into account that the liquid phase volume in the sonication  
208 vessel ( $V_{SoV}$ ) was 40 mL and the holding tube volume ( $V_{SeV}$ ) 52 mL, two residence  
209 time values were considered: the residence time in the sonication vessel ( $\tau_{SoV}$ ) and  
210 the total residence time ( $\tau_{ToT}$ ). These values were calculated using Eqs. (1) and (2).

211

212 
$$\tau_{SoV} = \frac{V_{SoV}}{q + q_{CO_2}} \quad (1)$$

213 
$$\tau_{ToT} = \frac{V_{SeV} + V_{SoV}}{q + q_{CO_2}} \quad (2)$$

214

215 Applying Eqs. (1) and (2) and considering the juice flow range (5-25 mL/min),  
216 the residence time limits resulted in  $1.333 < \tau_{SoV} < 4$  and  $3.0667 < \tau_{ToT} < 9.2$  minutes.

217 The experimental design is described in Table 1.

218

219 2.6. Statistical modeling

220 A boolean-real hybrid model was assessed in order to analyze the effect of the process  
 221 variables on the *S. cerevisiae* inactivation. The model was a function of the type  
 222  $f: \mathcal{A}^3 \times \mathcal{B} \rightarrow \mathcal{R}_+$  where  $\mathcal{A} = [-1, 1]$ ,  $\mathcal{B} = \{0, 1\}$  and  $\mathcal{R}_+$  is the positive field of real  
 223 numbers. This means that the three process variables were linearly codified as:  
 224  $x_1 = f_{11}(\tau_{soV})$  or  $x_1 = f_{11}(\tau_{ToT})$ ,  $x_2 = f_2(T)$  and  $x_3 = f_3(P)$  where  $f_1$ ,  $f_2$  and  $f_3$   
 225 are linear functions, in such a way that each combination  $(x_1, x_2, x_3) \in \mathcal{A}$ ; and a  
 226 Boolean variable  $x_4 \in \mathcal{B}$  is used to define the application or not of ultrasound. The  
 227 codified variables were defined in Eqs. 3-5.

228

$$229 \quad x_1 = \frac{\tau_{soV} - 2.667}{1.333} \in \mathcal{A} \quad \text{for the sonication vessel output} \quad (3a)$$

$$230 \quad x_1 = \frac{\tau_{ToT} - 6.133}{3.033} \in \mathcal{A} \quad \text{for the separation vessel output} \quad (3b)$$

$$231 \quad x_2 = \frac{T - 36}{5} \in \mathcal{A} \quad (4)$$

$$232 \quad x_3 = \frac{P - 200}{100} \in \mathcal{A} \quad (5)$$

233

234 where the constant values in Eqs. 3 to 5 were calculated so that any codified variable  
 235 must be in the range -1 to 1.

236

237 The Boolean variable is defined as,

238

$$239 \quad x_4 = \begin{cases} 0 & \text{for the process without ultrasound} \\ 1 & \text{for the process with ultrasound} \end{cases} \quad (6)$$

240

241 In order to ensure that the response was always positive, it was defined as Eq. 7.

242 
$$y = -\ln\left(\frac{N}{N_0}\right) \in \mathcal{R}_+ \quad (7)$$

243

244

245

246 Then, the hybrid model was defined by Eq. 8.

247 
$$y = (\beta_0 + \gamma_0 x_4) + (\beta_1 + \gamma_1 x_4)x_1 + (\beta_2 + \gamma_2 x_4)x_2 + (\beta_3 + \gamma_3 x_4)x_3 + (\beta_{11} + \gamma_{11} x_4)x_1^2$$

248 
$$+ (\beta_{12} + \gamma_{12} x_4)x_1 x_2 + (\beta_{13} + \gamma_{13} x_4)x_1 x_3 + (\beta_{22} + \gamma_{22} x_4)x_2^2$$

249 
$$+ (\beta_{23} + \gamma_{23} x_4)x_2 x_3 + (\beta_{33} + \gamma_{33} x_4)x_3^2 \quad (8)$$

250

251 With the hybrid model **proposed** it is possible to perform a statistical evaluation  
 252 of the effect of HPU through the significance of the  $\gamma$  parameters (Neter & Wasserman,  
 253 1978). The same model was fit separately to the two sets of experimental results: the  
 254 inactivation data for the sonication vessel outlet ( $x_1$  defined in Eq. 3a) and for the  
 255 separation vessel outlet ( $x_1$  defined in Eq. 3b).

256

### 257 **3. Results and Discussion**

258

259 The continuous flow SC-CO<sub>2</sub>-HPU equipment was used for the evaluation of the  
 260 effect of pressure, temperature and residence time on *S. cerevisiae* inactivation, for the  
 261 experimental design and under the conditions described in sections 2.1-2.5. The effect  
 262 of the process variables on inactivation was quantified through Eq. 8 parameters. The  
 263 value of the parameters obtained for the two sets of experimental results (samples  
 264 extracted in the sonication vessel and in the separator) and their statistical significance  
 265 are listed in Table 2. The fitted model had a determination coefficient ( $r^2$ ) of 0.92 for  
 266 the sonication vessel and 0.88 for the separator and an estimated variance ( $s^2$ ) of

267 0.418 and 0.364 for the sonication and separator vessels, respectively. The general  
268 behavior of the model with respect to residence time, pressure and operation mode  
269 (with and without US) is plotted in Figs. 2 and 3, and the individual effects of the  
270 process variables on the microbial inactivation are plotted in Figs. 4-6.

271

272

### 273 3.1. Effect of residence time and HPU

274 In Table 2, the significance probability of parameters  $\beta_1$ ,  $\beta_{12}$ ,  $\beta_{13}$ ,  $\beta_{11}$ ,  $\gamma_1$ ,  
275  $\gamma_{12}$ ,  $\gamma_{13}$  and  $\gamma_{11}$  indicates that residence time and operation mode (with and without  
276 US) are highly statistically significant in *S. cerevisiae* inactivation both in the sonication  
277 vessel and in the separator. The significance of second order interactions ( $\beta_{12}$ ,  $\gamma_{1, \dots}$ )  
278 and third order interactions ( $\gamma_{11}, \gamma_{22} \dots$ ), complicates the interpretation of the effects.  
279 Therefore, the graphical behavior of the model was plotted in Figs. 2 and 3. The model  
280 relates four process variables with one response, so, in order to be plotted in a 3D  
281 graph, it is necessary to fix two variables and plot the response as a function of the  
282 remaining two process variables. Fig. 2 plots the model behavior in the sonication  
283 vessel at a fixed temperature of 31 °C ( $x_2 = -1$ ) and for the two possibilities of the  
284 boolean variable: without ultrasound ( $x_4 = 0$ ) and with ultrasound ( $x_4 = 1$ ). Fig. 3  
285 shows the same information for the separator. Figs. 4, 5 and 6 show Eq. 8 behavior in  
286 2D projections and compare the fitted behavior with the experimental results under  
287 several process conditions. Fig. 4 plots Eq. 8 at a constant pressure and temperature  
288 (300 bar and 31 °C), whereas Eq. 8 at a constant pressure and flow is plotted in Figs. 5  
289 (100 bar and 15 mL/min) and 6 (200 bar and 15 mL/min).

290 From Figs. 2 and 3 and the  $\gamma_1$ ,  $\gamma_{12}$ ,  $\gamma_{13}$ ,  $\gamma_{11}$  values and their significance, it  
291 can be concluded that there is a significant effect ( $p < 0.01$ ) of HPU on microbial  
292 inactivation. In particular, compared to treatments without US, HPU increases the

293 inactivation of *S. cerevisiae* in the sonication and separation vessels by an average of  
294 1.5 log cycles and 2 log-cycles, respectively. The effect of HPU may be attributed to  
295 the enhancement of CO<sub>2</sub> mass transfer into the juice that accelerates the pH decrease  
296 in the liquid phase and the extraction of components, such as phospholipids and  
297 hydrophobic compounds, from *S. cerevisiae* cells. Another possible mechanism is the  
298 cavitation produced by HPU in the liquid phase (Gogate et al., 2011). Cavitation refers  
299 to the formation, growth, and implosion of tiny bubbles of CO<sub>2</sub> or water vapor in a liquid  
300 when ultrasounds travels through it. Cavitation has been proven to cause cracked or  
301 damaged cell walls, which enhances the penetration of SC-CO<sub>2</sub> inside the cells,  
302 changing the cellular equilibrium and facilitating the extraction of intracellular  
303 compounds, thus accelerating the death of the microbial cells. Ortuño et al. (2014)  
304 observed that after the SC-CO<sub>2</sub> + HPU treatment, the cell wall and cell membrane were  
305 totally disrupted, thus easing the disintegration of the cytoplasm and the inactivation of  
306 cells. The damage caused by the treatment was serious enough to prevent a possible  
307 regrowth of cells. Another effect of HPU is the increase in the internal cell component  
308 mass transfer and interfacial turbulence, accelerating the inactivation effect of CO<sub>2</sub>  
309 (Gao et al., 2009).

310 Table 2  $\beta_0$  value parameters and their significance indicate that there exists a  
311 maximum inactivation difference of 4 log-cycles in the separator with respect to the  
312 reactor. This difference shows that, although some inactivation is obtained in the  
313 sonication vessel, the holding tube as analog of a PFR complements the inactivation,  
314 providing enough contact time between the SC-CO<sub>2</sub> and the microbial cells for the  
315 microbial inactivation to be completed. In this regard, the SC-CO<sub>2</sub> dissolved into the  
316 juice in the holding tube penetrates the damaged cells and completes the inactivation  
317 mechanisms, leading to the maximum microbial death.

318 Figs. 4 a and b show that, regardless of the use of HPU, inactivation increases  
319 at the longest residence times. The effect of ultrasound is dependent on the total

320 residence time. At the shortest residence times, the HPU intensification can be clearly  
321 observed (Figs. 4a and b) and greater inactivation levels are obtained compared with  
322 treatments which only use SC-CO<sub>2</sub>. For example, at 9.2 min an inactivation of around 8  
323 log-cycles of *S. cerevisiae* was obtained regardless of whether HPU was used or not;  
324 however, at 3.06 min, 4.2 log-cycles were obtained without HPU and 5 log-cycles with  
325 HPU (Fig. 4b). The results relating the microbial inactivation to the residence time in  
326 the sonication vessel (Fig. 3a) are consistent with Ortuño et al. (2013). These authors  
327 reported an average inactivation of 5 log-cycles of *S. cerevisiae* (in YPD Broth) in 1.3  
328 min and 7 log-cycles in 2 min, for a SC-CO<sub>2</sub>-HPU batch treatment at different pressures  
329 (100, 225, 290 and 350 bar) and temperatures (31, 36 and 41 °C). However, using a  
330 batch SC-CO<sub>2</sub> (without HPU) system, Ortuño et al. (2013) reported an inactivation of *S.*  
331 *cerevisiae* in YPD Broth of less than 1 log-cycle after 50 min of contact time at 225 bar  
332 and 31-41 °C. Therefore, considering the inactivation obtained in the present study (8  
333 log-cycles at 9.2 min total residence time) without HPU, the continuous SC-CO<sub>2</sub>  
334 treatment system allows a better mixing of CO<sub>2</sub> in the juice and hence a greater  
335 dissolution and penetration into the microbial cells due to the fluid flow compared with  
336 batch treatments (Gunes et al., 2005; Shimoda et al., 1998).

337

### 338 3.2. Effect of pressure

339 The significance probability of Table 2  $\beta_3$ ,  $\beta_{13}$ ,  $\beta_{23}$ ,  $\beta_{33}$  and  $\gamma_{13}$  parameters  
340 indicates that pressure and its interaction with the operation mode are statistically  
341 significant as regards *S. cerevisiae* inactivation both in the sonication vessel and the  
342 separator. The generalized behavior of the pressure effect can be appreciated in Figs.  
343 2 and 3. It can be observed that the pressure effect is dependent on the other process  
344 variables. For example, the pressure effect is almost negligible at 1.33 min residence  
345 time ( $x_1 = -1$ ) without ultrasound in the sonication vessel (Fig 2b); and reaches a

346 maximum, with a difference of 4.3 log-cycles of inactivation between 300 and 100 bars,  
347 at 4 min ( $x_1 = 1$ ) without US in the sonication vessel (Fig 2b).

348 Several authors have previously studied *S. cerevisiae* inactivation. Spilimbergo  
349 and Mantoan (2005) and Erkmen (2003) concluded that the pressure increase had a  
350 positive effect on the inactivation treatment. CO<sub>2</sub> can diffuse into the cellular membrane  
351 and accumulate within the cells, since the plasmic membrane of a microbial cell  
352 consists of a lipid bilayer structure. At higher pressures, the amount of dissolved CO<sub>2</sub>  
353 increases and, therefore, a large number of CO<sub>2</sub> molecules can cross through the cell  
354 membrane and lower the internal pH enough to exceed the buffering capacity of the  
355 cytoplasmic content. The lowering of pH inside the cells might cause the inhibition  
356 and/or inactivation of key enzymes essential for metabolic and regulating processes,  
357 such as glycolysis, amino acids and peptide transport, the active transport of ions and  
358 proton translocation (Spilimbergo and Bertuccio, 2003).

359

### 360 3.3. Effect of temperature

361 The significance of Table 2  $\beta_{12}$  and  $\beta_{23}$  parameters for the sonication vessel  
362 indicates that temperature has a significant effect on *S. cerevisiae* inactivation.  
363 However, no interaction was found between temperature and the use of HPU in the  
364 sonication vessel, which can be observed in Figs.5a and 6a, where, although the  
365 application of HPU increases the inactivation by 3.7 log-cycles (quantified in  $\gamma_0$   
366 parameter), the slopes of both model lines are almost the same. On the contrary, in the  
367 separator, the significance of  $\beta_2$ ,  $\beta_{12}$ ,  $\beta_{23}$ ,  $\beta_{22}$ ,  $\gamma_{12}$  and  $\gamma_{23}$  parameters indicates  
368 that both temperature and its interaction with the use of HPU are statistically significant  
369 as regards *S. cerevisiae* inactivation, as can be observed in Fig. 5b. For example, at  
370 100 bar and 4.6 min of total residence time with ultrasound, in the separator vessel, a  
371 maximum inactivation difference of 1 log cycle can be obtained at the highest

372 temperature used (41 °C) with respect to the lowest one (31 °C), which indicates that  
373 the effect of temperature, although significant, is moderate.

374 Ortuño et al. (2013) studied the influence of HPU on *S. cerevisiae* inactivation  
375 kinetics using a batch SC-CO<sub>2</sub> system. These authors found a similar, moderate effect  
376 of temperatures between 31 and 41 °C on the microbial inactivation. The temperature  
377 effect is explained by the decrease in the medium's viscosity at higher temperatures,  
378 which causes an increase in the SC-CO<sub>2</sub> diffusivity, facilitating the penetration of SC-  
379 CO<sub>2</sub> into the cells and causing the extraction of essential substances from cells or  
380 membranes, cytoplasmic membranes and disorders in the organelles, and therefore,  
381 the disruption of the biological system in the cell (Shimoda et al., 1998).

382

### 383 3.4. Process optimization

384 As can be observed in the significance of the second and third order interaction  
385 parameters (Table 2), it is evident that the effect of process variables has strong  
386 interactions. However, the fitted descriptive model (Eq. 8) can be used to find the  
387 maximum potential of the proposed process. In order to increase the process  
388 productivity, the maximum potential of the process would be given by the minimum  
389 residence time that could be handled (maximum product flow), ensuring the desired  
390 number of log-cycles reduction. For the sonication vessel, Eq. 8 was considered for the  
391 optimization in order to show the actual potential of HPU however, the inactivation level  
392 reached in the separator was also calculated. Accordingly, a multi-objective  
393 optimization problem of two competitive variables (residence time vs microbial  
394 reduction) was formulated. The problem, solved as detailed in Carrillo-Ahumada et al.  
395 (2011), was formulated as follows:

396

397 Problem 1,

398

$$\text{Min } \tau_{SoV}$$

399

Subject to  $y_{SoV} \geq \phi$

400

and  $1.333 < \tau_{SoV} < 4$ ,  $31 < T < 41$ ,  $100 < P < 300$ ,  $0 < x_4 < 1$

401

402 Where  $\phi$  is the required number of log-cycles reduction. The optimization problem was  
403 solved, applying the Box-Ruiz-Rodríguez-García constraint optimization algorithm  
404 (Ruiz-López et al., 2006), at different values of  $\phi$  in order to obtain the maximum flows  
405 that could be achieved for microbial reductions ranging from 5 to 7 log-cycles. The  
406 optimum results are listed in Table 3 with superscript 1, 2 and 3. The results indicate  
407 that when optimization problem 1 was solved for  $\phi = 5$ , the competitive behavior  
408 between residence time vs microbial reduction was lost. This can be observed by the  
409 fact that the optimum was found in  $y = 5.5$ . Therefore, the maximum inactivation that  
410 can be obtained at 1.35 minutes or less of sonication vessel residence time, was  
411 sought by the following optimization problem,

412

413 Problem 2,

414

Max  $f(\tau_{SoV}, T, P, x_4)$

415

Subject to  $1.33 < \tau_{SoV} < 1.35$ ,  $31 < T < 41$ ,  $100 < P < 300$ ,  $0 < x_4 < 1$

416

417 The result of optimization problem 2 is listed in Table 3 with superscript 4. The  
418 microbial reduction obtained in the sonication vessel at optimum  $\tau_{SoV}$ ,  $T$  and  $P$  for  
419 problems 1 and 2, but with  $x_4 = 0$  (without HPU), is also listed in Table 3. The effect of  
420 HPU in the sonication vessel is clearly evident from the inactivation differences of 3.8,  
421 4.1, and 4.2 log cycles when HPU is used and when it is not (Table 3). The different  
422 inactivation parameters predicted by the optimization problems in the sonication vessel  
423 were used to calculate the inactivation in the separator (Table 3). As expected, an  
424 increase of inactivation (avg. 1 log-cycles with HPU and 3.3 without HPU) with respect

425 to the sonication vessel is obtained due to the longer residence time provided by the  
426 holding tube. The HPU effect in the separator vessel can be appreciated by the fact  
427 that, for the problem 2 optimum (subscript 4), there is a difference of 2.5 log cycles  
428 reduction when HPU is used and when not. The model developed was used to find the  
429 optimum working conditions by maximizing the flow; however, it could also be used for  
430 minimizing the process temperatures to increase the product quality.

431

432

#### 433 **4. Conclusions**

434 The designed and built continuous regime HPU-SC-CO<sub>2</sub> plant demonstrated a  
435 high capacity to inactivate (>7 log cycles) *S. cerevisiae* in apple juice. The results  
436 allowed the quantification of the effect of the process variables through the  
437 development of a hybrid real-boolean model that described the effect of real variables  
438 (residence time, temperature and pressure) and the discrete variable (application or not  
439 of HPU). Multi-objective optimal problems were developed in order to calculate the  
440 minimum residence time that can be handled to reach different minimum inactivation  
441 levels. The optimization results showed that the system can achieve an inactivation of  
442 6.8 log-cycles in 3.1 min of total residence time when HPU was applied, instead of 4.3  
443 log cycles (under the same conditions) without HPU, which shows how important the  
444 influence of HPU is on SC-CO<sub>2</sub> inactivation.

445

#### 446 **5. Acknowledgments**

447 This work was supported by the PROMETEOII\2014\005 project financed by the  
448 Generalitat Valenciana (Conselleria d'Educació, Cultura i Esport, Valencia, Spain). The  
449 authors acknowledge the Consejo Nacional de Ciencia y Tecnología (CONACyT) for  
450 the scholarship awarded to PhD Student Paniagua-Martínez, I. The authors especially  
451 wish to thank Eng. Ramón Peña for his technical assistance in the development of the  
452 equipment.

## Highlights

- An ultrasound assisted continuous supercritical CO<sub>2</sub> pasteurization system was built
- Continuous SC-CO<sub>2</sub> juice flow treatment greatly enhanced microbial inactivation
- Ultrasound considerably intensified inactivation using the continuous system
- 7.8 log-cycles inactivation obtained after 9.2 min residence time (300 bars; 31°C)
- Optimal process conditions were established through multivariate optimization

All of the treatments were carried out with and without ultrasound and were run in triplicate.

Table 2. Parameters of the model (Equation 8) used to describe the effect of pressure, temperature, residence time and use of ultrasound on the inactivation of *S. cerevisiae* using SC-CO<sub>2</sub>-HPU.

Parameter	Sonication vessel	p	Separator vessel	p
$\beta_0$	3.891	<0.01	8.29	<0.01
$\beta_1$	2.956	<0.01	3.744	<0.01
$\beta_2$	0.409	0.12	1.703	<0.01
$\beta_3$	0.916	<0.01	-0.2011	0.24
$\beta_{11}$	0.499	<0.01	-0.183	<0.01
$\beta_{12}$	0.622	0.05	1.582	<0.01
$\beta_{13}$	1.155	<0.01	-0.423	<0.01
$\beta_{22}$	0.069	0.67	-0.471	<0.01
$\beta_{23}$	-0.373	0.02	-0.972	<0.01
$\beta_{33}$	-0.484	<0.01	-0.621	<0.01
$\gamma_0$	3.24	<0.01	-0.964	<0.01
$\gamma_1$	-1.757	<0.01	-2.755	<0.01
$\gamma_2$	-0.131	0.74	-1.012	0.01
$\gamma_3$	-0.326	0.19	0.508	<0.01
$\gamma_{11}$	-1.09	<0.01	0.263	0.37
$\gamma_{12}$	-0.77	<0.01	-1.69	<0.01
$\gamma_{13}$	-0.844	<0.01	0.395	0.02
$\gamma_{22}$	-0.3825	<0.01	0.170	0.46
$\gamma_{23}$	0.0119	0.95	0.980	<0.01
$\gamma_{33}$	-0.1818	0.42	0.633	<0.01

p: probability that the parameter could be zero and therefore non-significant in the model

Table 3. Optimization results in the sonication ( $y_{SoV}$ ) and separation vessels ( $y_{SeV}$ ), calculated to minimize the residence time (problem 1) and to maximize the microbial inactivation (problem 2).

$\tau_{SoV}$ (min)	$q$ (mL/min)	$\tau_{TOT}$ (min)	$T$ (°C)	$P$ (bar)	$x_4$	$y_{SoV}$	$y_{SeV}$
2.40	11.7	5.52	37.6	231.1	1	7.0 <sup>1</sup>	7.4
2.40	11.7	5.52	37.6	231.1	0	3.5	7.4
1.66	19.1	3.82	37.4	219.3	1	6.0 <sup>2</sup>	6.9
1.66	19.1	3.82	37.4	219.3	0	1.9	5.4
1.35	24.6	3.10	39.0	216.7	1	5.5 <sup>3</sup>	6.9
1.35	24.6	3.10	39.0	216.7	0	1.3	4.2
1.35	24.6	3.10	39.4	203.4	1	5.5 <sup>4</sup>	6.8
1.35	24.6	3.10	39.4	203.4	0	1.3	4.3

Superscript 1-3: Optimization results obtained after minimizing the residence time, ensuring a given microbial inactivation ( $\phi$ ), 1:  $\phi \geq 7$ ; 2:  $\phi \geq 6$ ; 3:  $\phi \geq 5$ . Problem1.

Superscript 4: Optimization results obtained after maximizing the microbial inactivation, constrained by  $1.33 < \tau_{SoV} < 1.35$

For all the operating conditions that optimize the criteria (Superscript 1-4), in the row bellow, the corresponding inactivation without HPU ( $x_4=0$ ) is calculated.
