# Closure formula for ideals in intermediate rings 

John Paul Jala Kharbhin and Sanghita Dutta<br>Department of Mathematics, North Eastern Hill University, Mawkynroh, Umshing, Shillong - 22, India (jpkharbhih@gmail.com, sanghita22@gmail.com)<br>Communicated by F. Mynard

## Abstract

In this paper, we prove that the closure formula for ideals in $C(X)$ under $m$ topology holds in intermediate rings also. i.e. for any ideal $I$ in an intermediate ring with $m$ topology, its closure is the intersection of all the maximal ideals containing $I$.

KEYWORDS: m topology; rings of continuous functions; $\beta$-ideals.

## 1. Introduction

The m topology on $C(X)$ was defined by Hewitt in [9]. Let $C_{m}(X)$ denote the ring $C(X)$ equipped with $m$ topology. $C_{m}(X)$ was shown to be a topological ring. In any topological ring, the closure of a proper ideal is either a proper ideal or the whole ring [8, 2M1]. Amongst other results, Hewitt in [9] showed that every maximal ideal in $C(X)$ under m topology is closed. He conjectured that every m closed ideal of $C(X)$ is an intersection of maximal ideals of $C(X)$. This conjecture was settled by Gillman, Henriksen and Jerison [7]. It was also settled independently by T.Shirota [12]. In [7](also [8, 7Q.3]), it was further shown that the closed ideals in $C^{*}(X)$ (under subspace m topology) coincide with the intersections of maximal ideals in $C^{*}(X)$ if and only if $X$ is pseudocompact.

Intermediate rings denoted by $A(X)$, are rings of continuous functions which lie in between $C^{*}(X)$ and $C(X)$. These rings were studied by Donald Plank as $\beta$ - subalgebras in [10]. Subsequently, a number of researchers generated renewed interests in these intermediate rings as can be seen in [11], [5], [2], [4], [3] and [1].

Given a real number $\epsilon>0$ and $g \in A(X)$, let $E_{\epsilon}(g)[8,2 \mathrm{~L}]$ denote the set $\{x \in X:|g(x)| \leq \epsilon\}$. Given $\epsilon>0, f \in A(X)$, it is not difficult to construct a function $t$ satisfying $f t=1$ on the complement of $E_{\epsilon}(f)$. i.e. $E_{\epsilon}(f) \in \mathscr{Z}_{A}(f) \forall$ $\epsilon>0$. Given an ideal $I$ in $A(X)$, let $I^{\prime}$ denote the intersection of all the maximal ideals of $A_{m}(X)$ that contain $I$. Evidently $I^{\prime}$ is closed. Let $f \in A(X)$ and $E \in Z(X)$. Then, $f$ is said to be $E^{c}$-regular, if $\exists g \in A(X)$ such that $f g_{\left.\right|_{E^{c}}}=1$. For each $f \in A(X)$, let $\mathscr{Z}_{A}(f)$ denote the set $\{E \in Z(X): f$ is $E^{c}-$ regular $\}$. For an ideal $I$ of $A(X), \mathscr{Z}_{A}[I]$ denote the set $\bigcup_{f \in I} \mathscr{Z}_{A}(f)$. The set of cluster points of a z-filter $\mathscr{F}$ is denoted by $S[\mathscr{F}]$. An ideal $I$ in $A(X)$ is said to be a $\beta$-ideal if $\mathscr{Z}_{A}(f) \subset \mathscr{Z}_{A}[I] \Longrightarrow f \in I$. We shall denote intermediate rings $A(X)$ with m topology by $A_{m}(X)$. For undefined terms and references, we refer the reader to [8].

In this paper, we ask if Hewitt's formula for closure of an ideal holds for the case of $A_{m}(X)$ also. We answer this question in the affirmative, and as an outcome we obtain the result that an ideal in an intermediate ring is closed iff the ideal is a $\beta$-ideal.

Theorem 1.1 ([5, Theorem 3.3]). Let $M_{A}^{p}$ be the maximal ideal of $A(X)$ corresponding to the point $p$ of $\beta X$. Then

$$
M_{A}^{p}=\left\{f \in A(X): p \in S\left[\mathscr{Z}_{A}(f)\right]\right\} .
$$

## 2. Closure formula in intermediate rings

Let $U_{A}(X)$ denote the set of positive units of $A(X)$. For each $f \in A(X)$ and each $u \in U_{A}(X)$, let $B_{A}(f, u)$ denote the collection $\{g \in A(X):|f-g|<u\}$. For each $f \in A(X)$, the set $\mathscr{B}_{f}=\left\{B_{A}(f, u): u \in U_{A}(X)\right\}$ forms a base for the neighborhood system at $f$ and the topology so formed is the m topology in $A(X)$.

Definition 2.1. Let $A(X)$ be an intermediate subring. For an ideal $I$ in $A(X)$, let $\Delta_{A}(I)=\left\{p \in \beta X: M_{A}^{p} \supset I\right\}$.
Theorem 2.2. Let $I$ be an ideal in $A(X)$ and $p \in \beta X-\Delta_{A}(I)$. Then, $\exists f \in$ $I \cap C^{*}(X)$ such that $f^{\beta}(p)=1$.

Proof. Since $p \notin \Delta_{A}(I)$, so $M_{A}^{p} \not \supset I$. Therefore, $\exists g \in I$, such that $g \notin M_{A}^{p}$. So, $\exists$ a neighborhood $U$ of $p($ in $\beta X)$ which does not meet $E$, for some $E \in \mathscr{Z}_{A}(g)$. Now $E \in \mathscr{Z}_{A}(g) \Longrightarrow g l_{\left.\right|^{c}}=1$ for some $l \in A(X)$. Let $f \in C^{*}(X)$ be such that $0 \leq f \leq 1, f^{\beta}(p)=1$ and

$$
\begin{equation*}
f^{\beta}\left(U^{c}\right)=0 . \tag{2.1}
\end{equation*}
$$

We define $h: X \rightarrow \mathbb{R}$ by

$$
h(x)=\left\{\begin{array}{l}
\frac{f(x)}{\left(\frac{f f(x)+1) l(x) g(x)}{}, \text { if } x \in \operatorname{cl}_{\beta X} U \cap X\right.} \\
0, \text { if } x \in(\beta X-U) \cap X .
\end{array}\right.
$$

Then, $h$ is well-defined and continuous. In fact $h \in A(X)$ since $h \in C^{*}(X)$. Moreover the definition of $h$ shows that $f$ is a multiple of $g$ so that $f \in I$, which completes the proof.
Theorem 2.3. Let $\Omega$ be an open subset of $\beta X$ such that $\Omega \supset \Delta_{A}(I)$ for some ideal $I$ in $A(X)$. Then, given $\epsilon$ with $0<\epsilon<1, \exists g \in I$ with $0 \leq g \leq 1$ such that $\Omega \cap X \supset E_{\epsilon}(g)$.

Proof. Let $p \in \beta X-\Omega$. Then, $p \notin \Delta_{A}(I)$. By theorem 2.2 we see that $\exists g_{p} \in I \cap C^{*}(X)$ such that $g_{p}^{\beta}(p)=1$. We choose an $\epsilon \in \mathbb{R}$ with $0<\epsilon<1$. Let

$$
\Sigma_{p}=\left\{q \in \beta X: g_{p}^{\beta}(q)>\sqrt{\epsilon_{0}}\right\}
$$

Then, $\Sigma_{p}$ is open in $\beta X$ and non-empty as $p \in \Sigma_{p}$. Now, the collection $\left\{\Sigma_{p}: p \in \beta X-\Omega\right\}$ forms an open cover for the compact set $\beta X-\Omega$. Let $\left\{\Sigma_{p_{1}}, \Sigma_{p_{2}}, \ldots, \Sigma_{p_{n}}\right\}$ be a finite subcover of this open cover. Let $g=g_{p_{1}}^{2}+g_{p_{2}}^{2}+$ $\ldots+g_{p_{n}}^{2}$. For any $p \in \beta X-\Omega$, we then have $g^{\beta}(p)=\left(g_{p_{1}}^{\beta}(p)\right)^{2}+\left(g_{p_{2}}^{\beta}(p)\right)^{2}+$ $\ldots+\left(g_{p_{n}}^{\beta}(p)\right)^{2}>\epsilon$. Therefore, if $\left|g^{\beta}(p)\right| \leq \epsilon$, then $p \notin \beta X-\Omega$. i.e. $p \in \Omega$. Hence, $E_{\epsilon}(g) \subset \Omega \cap X$.

Definition 2.4. Let $f \in A(X)$. We say that $f$ is $Z C$-related to $I$, if $\exists \epsilon>0$, such that $Z(f) \supset C \supset E_{\epsilon}(g)$ for some cozero-set $C$ and some $g \in I$.

Definition 2.5. For an ideal $I$ of $A(X)$, we define

$$
K_{A}(I)=\{f \in A(X): f \text { is } Z C \text {-related to } I\}
$$

Theorem 2.6. For every ideal I of an intermediate subring $A_{m}(X)$, we have $K_{A}(I) \subset I$ and $c l_{m}\left(K_{A}(I)\right)=c l_{m}(I)$.
Proof. Let $f \in K_{A}(I)$. Then, $\exists \epsilon>0$ such that $Z(f) \supset C \supset E_{\epsilon}(g)$ for some cozero-set $C$ and some $g \in I$. Let us denote $E_{\epsilon}(g)$ by $E$. Since $E \in \mathscr{Z}_{A}(g)$, $\exists l \in A_{m}(X)$ such that $(g l)_{\left.\right|_{E^{c}}}=1$. Now, we define $h$ by

$$
h(x)=\left\{\begin{array}{l}
0, \text { if } x \in \operatorname{cl}_{X} C \\
\frac{f}{(|f|+1) l g} \text { if } x \notin C .
\end{array}\right.
$$

Then, $h$ is a well-defined bounded function. Moreover, $h$ is continuous. i.e. $h \in C^{*}(X) \subset A(X)$. Also, we get $f=h(|f|+1) l g$, which shows that $f \in I$. Thus $K_{A}(I) \subset I$ and hence $\operatorname{cl}_{m}\left(K_{A}(I)\right) \subset \operatorname{cl}_{m}(I)$. To prove that $\operatorname{cl}_{m}(I) \subset$ $\mathrm{cl}_{m}\left(K_{A}(I)\right)$, it is enough to prove that $I \subset \operatorname{cl}_{m}\left(K_{A}(I)\right)$. So, we take a $g \in I$. Let $\pi \in U_{A}(X)$. We define $f$ by

$$
f(x)=\left\{\begin{array}{l}
0, \text { if }-\frac{\pi(x)}{2} \leq g(x) \leq \frac{\pi(x)}{2} \\
g(x)-\frac{\pi(x)}{2}, \text { if } g(x)>\frac{\pi(x)}{2} \\
g(x)+\frac{\pi(x)}{2}, \text { if } g(x)<-\frac{\pi(x)}{2}
\end{array}\right.
$$

Then, $f$ lies in the $\pi$ neighborhood of $g$. We also notice that $f \in A_{m}(X)$ since $f$ may be rewritten as follows :

$$
f(x)=\left[\left(g(x)-\frac{\pi(x)}{2}\right) \vee 0\right]+\left[\left(g(x)+\frac{\pi(x)}{2}\right) \wedge 0\right]
$$

We shall now show that $f \in K_{A}(I)$. Let $C=\left\{x \in X:-\frac{\pi(x)}{2}<g(x)<\frac{\pi(x)}{2}\right\}$. Then $Z(f) \supset C$. Moreover, $C$ is the cozero-set of the function $h \in A(X)$ defined by:

$$
h(x)=\left(|g(x)|-\frac{\pi(x)}{2}\right) \wedge 0
$$

We choose any real number $\epsilon>0$ and define a function $\theta$ by $\theta(x)=\frac{4 \epsilon g(x)}{\pi(x)}$. Clearly, $\theta \in I$. Moreover $|\theta(x)| \leq \epsilon \Longleftrightarrow|g(x)| \leq \frac{\pi(x)}{4}$. In otherwords, $x \in E_{\epsilon}(\theta) \Longleftrightarrow|g(x)| \leq \frac{\pi(x)}{4}$. But, $|g(x)| \leq \frac{\pi(x)}{4} \Longrightarrow x \in Z(f)$. Hence $Z(f) \supset C \supset E_{\epsilon}(\theta)$ which completes the proof.
Example 2.7. Now, we will give an example of an ideal $I$ such that $K_{A}(I) \subsetneq I$. Let $X=\mathbb{R}$ and $A(X)=C(X)$. Let $I=M_{0}$. We will show that $K_{A}(I)=O_{0}$. Firstly, if $f \in O_{0}$, then $\exists$ an open set $C$ such that $0 \in C \subset Z(f)$. Now, $\exists \epsilon>0$ such that $E=[-\epsilon, \epsilon] \subset C$. Then $E=E_{\epsilon}(g)$, where $g$ is the identity map on $\mathbb{R}$. Moreover, $C$ is a cozero-set as $X$ is a metric space. Hence we have $f \in K_{A}(I)$. Secondly, if $f \in K_{A}(I)$, then $\exists g \in I, \epsilon>0$ such that $Z(f) \supset C \supset E_{\epsilon}(g)$ for some cozero-set $C$. Since $0 \in E_{\epsilon}(g)$, this gives that $Z(f)$ is a neighborhood of 0 i.e. $f \in O_{0}$.
Theorem 2.8. $k \in I^{\prime} \Longleftrightarrow S\left[\mathscr{Z}_{A}(k)\right] \supset \Delta_{A}(I)$.
Proof. $(\Rightarrow)$ We assume that $k \in I^{\prime}$. Let $p \in \Delta_{A}[I]$. Then, $M_{A}^{p} \supset I$ and so $k \in M_{A}^{p}$. By definition of $M_{A}^{p}, p \in S\left[\mathscr{Z}_{A}(k)\right]$.
$(\Leftarrow)$ Let $M_{A}^{p}$ be a maximal ideal which contains $I$. So, $p \in \Delta_{A}(I)$ and thus, $p \in S\left[\mathscr{Z}_{A}(k)\right]$. Therefore, $k \in M_{A}^{p}$ and hence $k \in I^{\prime}$.

We now prove the main result.
Theorem 2.9. The $m$ closure of any ideal $I$ in $A_{m}(X)$ is the intersection of all the maximal ideals containing $I$.
Proof. We have $\mathrm{cl}_{m}(I) \subset I^{\prime}$ as $I^{\prime}$ is closed. To prove $I^{\prime} \subset \operatorname{cl}_{m}(I)$, it is sufficient to prove that $K_{A}\left(I^{\prime}\right) \subset K_{A}(I)$. Then, by theorem 2.6, we will get $I^{\prime} \subset \operatorname{cl}_{m} I$.

Let $f \in K_{A}\left(I^{\prime}\right)$. Then, $\exists$ a cozero-set $C$, a real number $\epsilon>0$ and $\theta \in I^{\prime}$ such that

$$
\begin{equation*}
Z(f) \supset C \supset E_{\epsilon}(\theta)=E(\text { say }) \tag{2.2}
\end{equation*}
$$

Let $Z=X-C$. Then, $Z$ and $E$ are completely separated being disjoint zerosets. Therefore, $\exists h \in C^{*}(X), 0 \leq h \leq 1$ such that $h(E)=0$ and $h(Z)=1$.

Let $\Omega=\left\{p \in \beta X: h^{\beta}(p)<1\right\}$. We observe that $X=C \cup Z$, so $\beta X=$ $\operatorname{cl}_{\beta X} C \cup \operatorname{cl}_{\beta X} Z$. If $p \in \Omega$, i.e. $h^{\beta}(p)<1$, then $p \notin \operatorname{cl}_{\beta X} Z$ as $h^{\beta}\left(\operatorname{cl}_{\beta X} Z\right)=1$. So $p \in \mathrm{cl}_{\beta X} C$.

$$
\begin{equation*}
\text { i.e. } \operatorname{cl}_{\beta X} C \supset \Omega \text {. } \tag{2.3}
\end{equation*}
$$

Since $E \in \mathscr{Z}_{A}(\theta)$, therefore $\Omega \supset S\left[\mathscr{Z}_{A}(\theta)\right]$ because $p \in S\left[\mathscr{Z}_{A}(\theta)\right]$ gives $h^{\beta}(p)=0$. Hence by theorem 2.8 , we see that $\Omega \supset \Delta_{A}(I)$. Theorem 2.3 now gives a $g \in I$ with $0 \leq g \leq 1$ and some $\epsilon$ with $0<\epsilon<1$ such that

$$
\begin{equation*}
\Omega \cap X \supset E_{\epsilon}(g) \tag{2.4}
\end{equation*}
$$

From (2.2) and (2.3), we get,

$$
\operatorname{cl}_{\beta X} Z(f) \supset \operatorname{cl}_{\beta X} C \supset \Omega
$$

Then $\operatorname{cl}_{\beta X} Z(f) \cap X \supset \Omega \cap X$. Thus $Z(f) \supset \Omega \cap X$. Therefore, by (2.4) $Z(f) \supset \Omega \cap X \supset E_{\epsilon}(g)$. Finally, we have $\Omega \cap X$ is a co-zero-set as $\Omega \cap X=$ $\{p \in X: h(p)<1\}$.

Corollary 2.10. Every closed ideal is a $\beta$-ideal.
Proof. First we claim that an arbitrary intersection of $\beta$-ideals is also a $\beta$-ideal. Let $\left\{I_{\alpha}: \alpha \in \Lambda\right\}$ be a collection of $\beta$-ideals. Let $\mathscr{Z}_{A}(f) \subset \mathscr{Z}_{A}\left[\bigcap I_{\alpha}\right]$. Since each $I_{\alpha}$ is a $\beta$-ideal, it is enough to prove that $\mathscr{Z}_{A}(f) \subset \mathscr{Z}_{A}\left[I_{\alpha}\right] \forall \alpha \in \Lambda$, for this would imply that $f \in I_{\alpha} \forall \alpha \in \Lambda$. So take $E \in \mathscr{Z}_{A}(f)$. Therefore $E \in \mathscr{Z}_{A}(g)$ for some $g \in \bigcap_{\alpha \in \Lambda} I_{\alpha}$. This then gives $E \in \mathscr{Z}_{A}\left[I_{\alpha}\right] \forall \alpha \in \Lambda$. Now, let $I$ be a closed ideal in $A_{m}(X)$. Therefore, $I$ is an intersection of maximal ideals. But, as every maximal ideal is a $\beta$-ideal, therefore $I$ is an intersection of $\beta$-ideals and hence a $\beta$-ideal.

Remark 2.11. In [6, Theorem 3.13], it was shown that the $\beta$-ideals of an intermediate ring are just the intersections of maximal ideals of the ring. This says that $\beta$-ideals are closed, since maximal ideals are closed. Hence the class of $\beta$-ideals and the class of closed ideals in intermediate rings coincide. This coincidence also occurs in the case of the subring $C^{*}(X)$ with $m$ topology. Here, the class of e-ideals is the same as the class of closed ideals $[8,2 \mathrm{M}]$. However, this coincidence does not extend to z-ideals in $C_{m}(X)$ since the ideal $O^{p}$ is a z-ideal which is not closed.

Remark 2.12. In [1], it was proven that if an intermediate ring $A(X)$ is different from $C(X)$, then there exists at least one non-maximal prime ideal $P$ in $A(X)$. Thus, $P$ is not closed in $A_{m}(X)$. On the other hand if $A(X)=C(X)$ and $X$ is a P space then each ideal in $A_{m}(X)$ is closed [8, 7Q4]. Thus within the class of P spaces $X$, for an intermediate ring $A(X)$, each ideal in $A_{m}(X)$ is closed $\Longleftrightarrow A(X)=C(X)$ - this is a special property of $C(X)$ which distinguishes $C(X)$ amongst all the intermediate rings (in the category of P spaces $X$ ).

Acknowledgements. The authors would like to thank the referee for the valuable comments and suggestions towards the improvement of the paper. In particular, Remark 2.12 is due to the referee.
