# Mean ergodic operators and reflexive Fréchet lattices

José Bonet\*, Ben de Pagter† and Werner J. Ricker

## Abstract

Connections between (positive) mean ergodic operators acting in Banach lattices and properties of the underlying lattice itself are well understood; see the works of Emel'yanov, Wolff and Zaharopol cited in the references. For Fréchet lattices (or more general locally convex solid Riesz spaces) there is virtually no information available. For a Fréchet lattice  $E$ , it is shown here (amongst other things) that every power bounded linear operator on  $E$  is mean ergodic if and only if  $E$  is reflexive if and only if  $E$  is Dedekind  $\sigma$ -complete and every positive power bounded operator on  $E$  is mean ergodic if and only if every positive power bounded operator in the strong dual  $E'_\beta$  (no longer a Fréchet lattice) is mean ergodic. An important technique is to develop criteria which detect when  $E$  admits a (positively) complemented lattice copy of  $c_0$ ,  $\ell_1$  or  $\ell_\infty$ .

## 1 Introduction and statement of results

A continuous linear operator  $T$  in a Banach space  $E$  (or locally convex Hausdorff space, briefly lcHs) is called *mean ergodic* if the limits

$$\lim_{n \rightarrow \infty} \frac{1}{n} \sum_{m=1}^n T^m x, \quad x \in E, \quad (1)$$

exist (in the topology of  $E$ ). J. von Neumann (1931) proved that unitary operators in Hilbert space are mean ergodic. Ever since, intensive research has been undertaken concerning mean ergodic operators and their applications; for the period up to the 1980's see [13], Ch. VIII, Section 4, [18], Ch. XVIII, [20], Ch. 2, and the references therein.

It quickly became evident that there was an intimate connection between geometric properties of the underlying Banach space  $E$  and mean ergodic operators on  $E$ . A continuous linear operator  $T$  in  $E$  (the space of all such operators is denoted by  $\mathcal{L}(E)$ ) is called *power bounded* if  $\sup_{m \geq 0} \|T^m\| < \infty$ . The space  $E$  itself is called *mean ergodic* if for every power bounded  $T \in \mathcal{L}(E)$  the limits

*Key words and phrases*: mean ergodic operator, power bounded, Fréchet lattice, locally solid Riesz space

(1) exist. As a sample, F. Riesz (1938) showed that all  $L_p$ -spaces ( $1 < p < \infty$ ) are mean ergodic. In 1938, E.R. Lorch proved that all reflexive Banach spaces are mean ergodic. In the opposite direction, in 2001 V.P. Fonf, M. Lin and P. Wojtaszczyk, [16], established (amongst other things) that a Banach space  $E$  with a basis is reflexive if and only if  $E$  is mean ergodic. For *Banach lattices* the requirement of a basis can be omitted. Indeed, in 1986, R. Zaharopol showed that if  $E$  is a Dedekind  $\sigma$ -complete Banach lattice, then  $E$  is reflexive if and only if every *positive* power bounded operator  $T \in \mathcal{L}(E)$  is mean ergodic, [30]. For an arbitrary Banach lattice  $E$ , it was shown by E.Yu. Emel'yanov in 1997, [14], that  $E$  is reflexive if and only if every *regular* power bounded operator  $T \in \mathcal{L}(E)$  is mean ergodic (regular means that  $T$  is the difference of two positive operators). According to E.Yu. Emel'yanov and M.P.H. Wolff, [15], a Banach lattice has order continuous norm if and only if every *power order bounded* operator on  $E$  is mean ergodic.

For a lchS  $E$ , the definition of  $T \in \mathcal{L}(E)$  being mean ergodic (i.e., via (1)) makes perfectly good sense, as does the notion of power boundedness, now meaning that  $\{T^m\}_{m \geq 0}$  is an equicontinuous subset of  $\mathcal{L}(E)$ . The first "mean ergodic result" for (a special class of) power bounded operators  $T$  on certain lchS'  $E$  is due to M. Altman, [6]. The restriction on  $T$  that Altman imposed (a weak compactness condition) was later removed by K. Yosida ([28], Ch. VIII). In more recent times, most of the Banach space results mentioned above which connect geometric properties of the underlying space  $E$  to mean ergodicity of operators acting on  $E$  were extended to the *Fréchet space* setting in [1] and to more general lchS'  $E$  in [2], [3] and [8]. The aim of this article is to extend the above results concerned with mean ergodic operators in Banach lattices to the setting of *Fréchet lattices*. Classical examples of Fréchet lattices to keep in mind include the sequence space  $\omega = \mathbb{R}^{\mathbb{N}}$  and all Köthe echelon spaces  $\lambda_p(A)$  for  $p \in \{0\} \cup [1, \infty]$ , with  $A$  a Köthe matrix relative to some countable index set (see e.g. [22]). We also mention  $\ell^{p+}$ ,  $1 \leq p < \infty$  (see [23]) and  $L^{p-}$ ,  $1 < p < \infty$  (see [11]). Further examples are  $L_{loc}^p(\Omega)$  for  $1 \leq p \leq \infty$  with  $\Omega \subseteq \mathbb{R}^N$  open and  $C(\Omega)$ , equipped with the topology of uniform convergence on compact subsets of  $\Omega$ . Finally, if  $m$  is any Fréchet space valued vector measure, then the spaces  $L^p(m)$  (respectively,  $L_w^p(m)$ ) consisting of the  $p$ -th power  $m$ -integrable (respectively, weakly  $m$ -integrable) functions are Fréchet lattices (see [9], [10], [25]).

So, let us formulate some of the main results. General references for the theory of lchS' are [19], [22] and [26]. If  $\Gamma_E$  is a system of continuous seminorms generating the topology of a lchS  $E$ , then the *strong operator topology*  $\tau_s$  in  $\mathcal{L}(E)$  is determined by the seminorms

$$q_x(S) = q(Sx), \quad S \in \mathcal{L}(E), \quad (2)$$

for each  $x \in E$  and  $q \in \Gamma_E$  (in which case we write  $\mathcal{L}_s(E)$ ). The *uniform operator topology*  $\tau_b$  in  $\mathcal{L}(E)$  is defined via the seminorms

$$q_B(S) = \sup_{x \in B} q(Sx), \quad S \in \mathcal{L}(E), \quad (3)$$

for each  $q \in \Gamma_E$  and bounded set  $B \subseteq E$  (in which case we write  $\mathcal{L}_b(E)$ ). If  $E$  is a Banach space, then  $\tau_b$  is the operator norm topology on  $\mathcal{L}(E)$ . A *Fréchet space* is a complete, metrizable lchS  $E$ , in which case  $\Gamma_E$  may be taken

countable. The topological dual space of a lcHs  $E$  is denoted by  $E'$ . The weak topology induced on  $E$  by the pairing  $\langle E, E' \rangle$  is written as  $\sigma(E, E')$  and the strong topology on  $E$  (respectively  $E'$ ) is denoted by  $\beta(E, E')$  (respectively  $\beta(E', E)$ ), in which case we write  $E_\beta$  (respectively  $E'_\beta$ ). Then,  $E'_\beta$  is called the strong dual of  $E$  and  $E'' = \left(E'_\beta\right)'_\beta$  is the strong bidual of  $E$ . If  $E = E''$  as vector spaces (respectively, additionally topologically), then  $E$  is called semireflexive (respectively, reflexive). For a Fréchet space  $E$ , the strong dual  $E'_\beta$  need not be metrizable but,  $E''$  is again a Fréchet space containing  $E$  as a closed subspace ([22], Corollary 25.10).

Relevant references for the theory of Riesz spaces (which will always be over  $\mathbb{R}$ ), with  $\leq$  denoting the order, are [21], [24], [29]. For locally convex-solid Riesz spaces  $E$  (briefly lc-solid Riesz spaces) we refer to [4], [5], [17], for example. In this case, the seminorms  $q \in \Gamma_E$  can all be chosen to be *Riesz seminorms*, that is,  $q(x) \leq q(y)$  whenever  $|x| \leq |y|$  in  $E$  ([4], Theorem 6.1). As usual, a linear operator  $T \in \mathcal{L}(E)$  is called *positive* if  $Tx \geq 0$  whenever  $x \in E^+$ , where  $E^+ = \{x \in E : x \geq 0\}$  is the positive cone of  $E$ . A Riesz space  $E$  is said to be Dedekind ( $\sigma$ -) complete if every non-empty (countable) subset of  $E$  that is order bounded from above has a supremum. Typical examples of Riesz spaces which fail to be Dedekind  $\sigma$ -complete are the sequence space  $c$  and the space of continuous functions  $C([0, 1])$ .

A lc-solid Riesz space which is metrizable and complete is simply called a *Fréchet lattice* ([4], p. 111).

**Theorem 1.1** *If  $E$  is a Fréchet lattice, then the following assertions are equivalent.*

- (i)  $E$  is reflexive.
- (ii)  $E$  is mean ergodic.
- (iii)  $E$  is Dedekind  $\sigma$ -complete and every positive power bounded operator on  $E$  is mean ergodic.
- (iv) Every positive, power bounded operator on  $E'_\beta$  is mean ergodic.

The main tool needed to establish Theorem 1.1 is of interest in its own right. Two lc-solid Riesz spaces  $E$  and  $F$  are called *Riesz homeomorphic* if there exists a *Riesz homeomorphism*  $J : E \rightarrow F$  (that is,  $J$  is a linear lattice homomorphism from  $E$  onto  $F$  which is also a homeomorphism). If  $E$  contains a Riesz subspace which is Riesz homeomorphic to  $F$ , then we say that  $E$  contains a *lattice copy* of  $F$ . As usual, a closed Riesz subspace  $F$  of a lc-solid Riesz space  $E$  is said to be (*positively*) *complemented* in  $E$  if  $F$  is the range of a linear continuous (positive) projection.

Crucial for establishing Theorem 1.1 is the following result.

**Theorem 1.2** *If  $E$  is a Dedekind  $\sigma$ -complete lc-solid Riesz space which is complete and  $\aleph_0$ -barrelled, then the following assertions are equivalent.*

- (i)  $E$  is not semireflexive.
- (ii)  $E$  contains a lattice copy of either  $\ell_\infty$ ,  $\ell_1$  or  $c_0$ .

The relevance of the Banach lattices  $c_0$ ,  $\ell_1$  and  $\ell_\infty$  is that each one admits a positive power bounded operator which *fails* to be mean ergodic. Indeed, denoting the elements in these sequence spaces by  $x = (x_1, x_2, \dots)$ , it can be verified that the operators

$$\begin{aligned} T_0 : x &\longmapsto (x_1, x_1, x_2, x_3, \dots), & x \in c_0, \\ T_1 : x &\longmapsto (0, x_1, x_2, x_3, \dots), & x \in \ell_1, \\ T_\infty : x &\longmapsto (x_2, x_3, x_4, \dots), & x \in \ell_\infty, \end{aligned} \tag{4}$$

on the spaces  $c_0$ ,  $\ell_1$  and  $\ell_\infty$  respectively, have the stated properties.

Given a Riesz space  $E$ , a linear map  $T : E \rightarrow E$  is called *power order bounded* if, for every  $x \in E^+$  there exists  $z \in E^+$  such that

$$\bigcup_{m=0}^{\infty} T^m([-x, x]) \subseteq [-z, z],$$

where  $[-u, u]$  denotes the order interval  $\{y \in E : -u \leq y \leq u\}$ , for each  $u \in E^+$ . Order intervals in a lc-solid Riesz space  $E$  are always topologically bounded ([4], Theorem 5.4). Hence, if  $E$  is barrelled and  $T \in \mathcal{L}(E)$  is power order bounded, then the uniform boundedness principle implies that  $T$  is power bounded ([22], Proposition 23.27).

Recall that a lc-solid Riesz space  $E$  has a ( $\sigma$ -) *Lebesgue topology* if, for every decreasing (sequence) net  $x_\alpha \downarrow_\alpha 0$  it follows that  $x_\alpha \rightarrow_\alpha 0$  with respect to the given topology ([4], p. 52). For Banach lattices this notion corresponds to ( $\sigma$ -) order continuity of the norm ([24], Ch. 2, Section 4). The extension of the above mentioned result of Emel'yanov and Wolff can now be formulated.

**Theorem 1.3** *For a Fréchet lattice  $E$  the following assertions are equivalent.*

- (i)  *$E$  has a Lebesgue topology.*
- (ii) *Every power order bounded operator on  $E$  is mean ergodic.*

We mention that Theorems 1.1-1.3 will actually be established in somewhat more generality than the (more transparent) versions formulated above.

For a Banach space  $E$  *with a basis* it is known that  $E$  is uniformly mean ergodic if and only if  $E$  is finite dimensional ([16], Corollary 3). Here, a lcHs  $E$  is called *uniformly mean ergodic* if every power bounded operator  $T$  on  $E$  has the property that its Cesàro means

$$T_{[n]} = \frac{1}{n} \sum_{m=1}^n T^m, \quad n \in \mathbb{N}, \tag{5}$$

form a convergent sequence in  $\mathcal{L}_b(E)$ . For Banach lattices the requirement of a basis can be omitted.

**Theorem 1.4** *A Banach lattice  $E$  is uniformly mean ergodic if and only if  $E$  is finite dimensional.*

It is known that every Montel Fréchet lattice (e.g.  $\omega$  or  $\lambda_p(A)$ ,  $1 \leq p \leq \infty$ , for those Köthe matrices  $A$  such that  $\lambda_1(A)$  is reflexive; [22], Theorem 27.9) is necessarily uniformly mean ergodic ([1], Proposition 2.8). Our final result may be viewed as an analogue of Theorem 1.4 for non-normable Fréchet lattices. We point out that every Montel Fréchet lattice is necessarily discrete ([4], Corollary 21.13).

**Theorem 1.5** *A Fréchet lattice  $E$  is Montel if and only if  $E$  is discrete and uniformly mean ergodic.*

## 2 Some preliminary results

For a Riesz space  $E$ , we recall that the *order dual*  $E^\sim$  is always a Dedekind complete Riesz space ([4], Theorem 3.3). A classical result of F. Riesz states that in any Dedekind complete Riesz space  $E$ , every band  $B$  is a *projection band*, that is,  $E = B \oplus B^d$  or, equivalently, there exists a linear projection  $P : E \rightarrow E$  with range  $\text{Im}(P) = B$  and satisfying  $Px \in [0, x]$ ,  $x \in E^+$  ([4], Theorem 2.12; [24], Theorem 1.2.9). Such a projection  $P$  is called a *band projection* in  $E$  (note that if  $E$  is a lc-solid Riesz space, then every band projection  $P$  is continuous, because  $|Px| \leq |x|$  for  $x \in E$ ). Here,  $B^d = \{x \in E : |x| \wedge |y| = 0, \forall y \in B\}$ .

If  $E$  is a lc-solid Riesz space, then  $E'_\beta$  is also a lc-solid Riesz space whose topology is given by the family of Riesz seminorms

$$q_B(x') = \sup_{x \in B} |\langle x, x' \rangle|, \quad x' \in E'_\beta, \quad (6)$$

as  $B$  runs through the collection  $\mathcal{B}_s$  of all bounded, solid subsets of  $E$  ([4], pp. 59, 129). Moreover,  $E'_\beta$  is an ideal in  $E^\sim$  and so, in particular,  $E'_\beta$  is Dedekind complete ([4], Theorem 5.7). If  $E$  happens to be barrelled, then  $E'_\beta$  is a *band* in  $E^\sim$  ([4], Theorem 6.4). Consequently,  $E'_\beta$  is then topologically complete ([4], Theorem 19.13).

We will require the following result on extending linear functionals ([29], Theorem 83.17).

**Theorem 2.1** *Let  $E$  be a Riesz space,  $F \subseteq E$  be a Riesz subspace (i.e., vector sublattice) and  $\theta : E \rightarrow \mathbb{R}$  be a sublinear functional which is absolute (i.e.,  $\theta(x) = \theta(|x|)$ ,  $x \in E$ ) and monotone on  $E^+$  (i.e.,  $\theta(x) \leq \theta(y)$  whenever  $0 \leq x \leq y$  in  $E$ ). If  $\varphi : F \rightarrow \mathbb{R}$  is a positive linear functional satisfying  $|\langle x, \varphi \rangle| \leq \theta(x)$  for  $x \in F$ , then there exists a positive linear functional  $\psi : E \rightarrow \mathbb{R}$  such that  $\psi|_F = \varphi$  and  $|\langle x, \psi \rangle| \leq \theta(x)$  for  $x \in E$ .*

As an immediate application, we present a result which is well known in the Banach lattice setting ([24], Proposition 2.3.11).

**Proposition 2.2** *If  $F$  is a lattice copy of  $\ell_1$  in a lc-solid Riesz space  $E$ , then*

- (i)  *$F$  is positively complemented in  $E$ , and*
- (ii)  *$E'_\beta$  contains a lattice copy of  $\ell_\infty$ .*

**Proof.** (i). Let  $\|\cdot\|_1$  be a Riesz norm on  $F$  such that the topology of  $F$  induced by  $E$  is given by  $\|\cdot\|_1$  and  $(F, \|\cdot\|_1)$  is Riesz isometric to  $\ell_1$ . In particular, there exists a continuous Riesz seminorm  $r$  on  $E$  such that

$$\|x\|_1 \leq r(x), \quad x \in F.$$

Let  $\{v_n\}_{n=1}^\infty \subseteq F$  correspond to the standard unit basis vectors of  $\ell_1$  (so that  $\|v_n\|_1 = 1$  for all  $n \in \mathbb{N}$ ).

For each  $x \in F$  there exists a unique sequence  $\{\alpha_n(x)\}_{n=1}^\infty \in \ell_1$  satisfying  $x = \sum_{n=1}^\infty \alpha_n(x) v_n$ , with the series convergent in  $(F, \|\cdot\|_1)$ . Note that  $x \in F^+$  if and only if  $\alpha_n(x) \geq 0$  for all  $n \in \mathbb{N}$ . Since  $|\alpha_n(x)| \leq \|x\|_1 \leq r(x)$  for  $x \in F$ , it is clear that  $\alpha_n \in (F')^+$  for all  $n \in \mathbb{N}$ , where  $\langle x, \alpha_n \rangle = \alpha_n(x)$ ,  $x \in F$ . Define the positive linear functional  $y'_1 \in F'$  by setting

$$\langle x, y'_1 \rangle = \sum_{k=1}^\infty \langle x, \alpha_k \rangle, \quad x \in F,$$

in which case

$$|\langle x, y'_1 \rangle| \leq \langle |x|, y'_1 \rangle \leq r(|x|) = r(x), \quad x \in F.$$

Evidently,  $0 \leq \alpha_n \leq y'_1$  for all  $n \in \mathbb{N}$ . By Theorem 2.1, applied to  $\theta = r$  and  $\varphi = y'_1$ , there exists  $0 \leq x'_1 \in E^\sim$  with  $x'_1|_F = y'_1$  such that  $|\langle x, x'_1 \rangle| \leq r(x)$ ,  $x \in E$ . In particular,  $x'_1 \in (E')^+$ . Since, for each  $n \in \mathbb{N}$ ,

$$|\langle x, \alpha_n \rangle| \leq \langle |x|, \alpha_n \rangle \leq \langle |x|, y'_1 \rangle = \langle |x|, x'_1 \rangle, \quad x \in F,$$

it follows from Theorem 2.1 that there exists  $0 \leq z'_n \in E^\sim$  with  $z'_n|_F = \alpha_n$  such that  $|\langle x, z'_n \rangle| \leq \langle |x|, x'_1 \rangle$  for  $x \in E$ . In particular,  $z'_n \in (E')^+$  and  $0 \leq z'_n \leq x'_1$  for all  $n \in \mathbb{N}$ . Let  $\varphi_n$  be the minimal positive extension of the restriction of  $z'_n$  to the principal ideal  $E_{v_n}$  generated by  $v_n$  in  $E$  (see [29], Theorems 83.7 and 83.8). It follows from  $0 \leq \varphi_n \leq z'_n$  that  $\varphi_n \in (E')^+$  and  $0 \leq \varphi_n \leq x'_1$  for all  $n$ . Since  $\langle v_m, \varphi_n \rangle = \delta_{n,m}$  for all  $n, m \in \mathbb{N}$ , it is clear that  $\varphi_n|_F = \alpha_n$ . Furthermore, since  $v_n \wedge v_m = 0$  ( $n \neq m$ ), it can be verified (see [5], Exercise 2.3) that  $\varphi_n \wedge \varphi_m = 0$  in  $E'$  whenever  $n \neq m$ .

If  $x \in E$ , then

$$\sum_{k=1}^n |\langle x, \varphi_k \rangle| \leq \sum_{k=1}^n \langle |x|, \varphi_k \rangle = \langle |x|, \bigvee_{k=1}^n \varphi_k \rangle \leq \langle |x|, x'_1 \rangle$$

for all  $n \in \mathbb{N}$  and so,  $\sum_{k=1}^\infty |\langle x, \varphi_k \rangle| < \infty$ . Consequently,

$$\sum_{n=1}^\infty \|\langle x, \varphi_n \rangle v_n\|_1 = \sum_{n=1}^\infty |\langle x, \varphi_n \rangle| < \infty, \quad x \in E.$$

Hence, the series

$$Px = \sum_{n=1}^\infty \langle x, \varphi_n \rangle v_n, \quad x \in E, \quad (7)$$

converges in the complete space  $F$ . It is now clear that  $P$  is a positive projection in  $E$  onto  $F$ .

(ii). Using the notation introduced in the proof of (i), define the map  $\Phi_0 : \ell_\infty^+ \rightarrow (E')^+$  by setting

$$\Phi_0(\lambda) = \bigvee_{n=1}^\infty \lambda_n \varphi_n, \quad 0 \leq \lambda = (\lambda_n) \in \ell_\infty^+.$$

Since  $0 \leq \varphi_n \leq x'_1$  for all  $n$  and  $E'$  is Dedekind complete, this map is well defined and satisfies  $0 \leq \Phi_0(\lambda) \leq \|\lambda\|_\infty x'_1$  for  $\lambda \in \ell_\infty^+$ . Since  $\{\varphi_n\}_{n=1}^\infty$  is a disjoint system in  $(E')^+$ , it is clear that  $\Phi_0$  is additive, positive homogeneous and that  $\Phi_0(\lambda) \wedge \Phi_0(\mu) = 0$  whenever  $\lambda \wedge \mu = 0$  in  $\ell_\infty^+$ . Therefore,  $\Phi_0$  has a unique extension to a Riesz homomorphism  $\Phi : \ell_\infty \rightarrow E'$  ([4], Theorem 1.17

and Lemma 3.1). We claim that  $\Phi$  is a linear homeomorphism from  $\ell_\infty$  onto its range in  $E'_\beta$ . Indeed, if  $p$  is *any* Riesz seminorm on  $E'$ , then

$$p(\Phi(\lambda)) = p(\Phi(|\lambda|)) \leq \|\lambda\|_\infty p(x'_1), \quad \lambda \in \ell_\infty.$$

On the other hand, if  $B$  is the convex solid hull in  $E$  of the bounded set  $\{v_n\}_{n=1}^\infty$ , then the continuous Riesz seminorm  $q_B$  on  $E'_\beta$ , defined by (6), satisfies  $q_B(\varphi_n) = 1$  for all  $n \in \mathbb{N}$ . If  $\lambda = (\lambda_n) \in \ell_\infty$ , then

$$|\Phi(\lambda)| = \Phi(|\lambda|) \geq |\lambda_n| \varphi_n$$

and so,  $q_B(\Phi(\lambda)) \geq |\lambda_n|$  for all  $n \in \mathbb{N}$ . This implies that  $q_B(\Phi(\lambda)) \geq \|\lambda\|_\infty$ ,  $\lambda \in \ell_\infty$ , and we may conclude that  $\Phi$  is a linear homeomorphism. The proof is complete. ■

**Remark 2.3** (a) It can be verified that the adjoint  $P' \in \mathcal{L}(E'_\beta)$  of the projection  $P$  in  $E$  defined by (7) is a positive projection in  $E'_\beta$  onto the lattice copy  $\Phi(\ell_\infty)$  of  $\ell_\infty$  in  $E'_\beta$ , as constructed in (ii) of the above proof.

(b) Any lattice copy of  $\ell_\infty$  in a lc-solid Riesz space  $E$  is positively complemented. Indeed, suppose that  $F$  is a Riesz subspace of  $E$  and let  $J : \ell_\infty \rightarrow F$  be a Riesz homeomorphism. For every continuous Riesz seminorm  $p$  on  $E$  there exists a constant  $C_p \geq 0$  such that  $p(J\lambda) \leq C_p \|\lambda\|_\infty$  for  $\lambda \in \ell_\infty$ . There also exists a continuous Riesz seminorm  $q$  on  $E$  such that  $\|\lambda\|_\infty \leq q(J\lambda)$  for  $\lambda \in \ell_\infty$ . For each  $n \in \mathbb{N}$ , define the positive linear functional  $\varphi_n$  on  $F$  by  $\langle x, \varphi_n \rangle = (J^{-1}x)(n)$ ,  $x \in F$ , where  $(J^{-1}x)(n)$  denotes the  $n$ -th coordinate of  $J^{-1}x$ . Note that  $J^{-1}x = (\langle x, \varphi_n \rangle)$  and hence,  $J(\langle x, \varphi_n \rangle) = x$  for all  $x \in F$ . Since

$$|\langle x, \varphi_n \rangle| = |(J^{-1}x)(n)| \leq \|J^{-1}x\|_\infty \leq q(x), \quad x \in F,$$

it follows from Theorem 2.1 that, for each  $n \in \mathbb{N}$ , there exists a positive linear functional  $\psi_n$  on  $E$  such that  $\psi_n|_F = \varphi_n$  and  $|\langle x, \psi_n \rangle| \leq q(x)$ ,  $x \in E$  (and so,  $0 \leq \psi_n \in E'$ ). It is clear that  $(\langle x, \psi_n \rangle) \in \ell_\infty$  for all  $x \in E$ . Defining the map  $P : E \rightarrow E$  via

$$Px = J(\langle x, \psi_n \rangle), \quad x \in E,$$

it can be checked that  $P$  is a positive continuous projection in  $E$  onto  $F$ . This proves the claim.

**Proposition 2.4** *Suppose that  $E$  is a sequentially complete, lc-solid Riesz space, with the property that countable, bounded subsets of  $E'_\beta$  are equicontinuous. If  $E'_\beta$  contains a lattice copy of  $c_0$ , then  $E$  contains a positively complemented lattice copy of  $\ell_1$ .*

**Remark 2.5** (i) Every  $\aleph_0$ -barrelled lcHs  $E$  has the property that countable, bounded subsets of  $E'_\beta$  are equicontinuous ([26], Observation 8.2.2 (a)). All barrelled (hence, all Fréchet) lcHs' are  $\aleph_0$ -barrelled ([26], Observation 8.2.2 (b)); the same is true for all complete  $(DF)$ -spaces ([26], Observation 8.2.2 (c)), which include the strong duals of Fréchet spaces.

(ii) For  $E$  a Banach lattice, Proposition 2.4 occurs in [24], Proposition 2.3.12.

**Proof.** (of Proposition 2.4) The idea of the proof follows the lines of that of implication (iii) $\Rightarrow$ (i) in [24], Proposition 2.3.12, with various modifications required due to the new setting.

Let  $F$  be a lattice copy of  $c_0$  in  $E'_\beta$  and let  $\{x'_n\}_{n=1}^\infty \subseteq F$  correspond to the standard unit basis vectors of  $c_0$ , in which case  $x'_n \geq 0$ ,  $n \in \mathbb{N}$ . Then  $\{x'_n\}_{n=1}^\infty$  is a bounded subset of  $E'_\beta$  which is *not* a null sequence. Hence, there exists a set  $B \in \mathcal{B}_s$  such that  $q_B(x'_n) \rightarrow 0$  as  $n \rightarrow \infty$ , with  $q_B$  given by (6). So, by passing to a subsequence if necessary, there exists  $\delta > 0$  such that  $q_B(x'_n) \geq \delta$ ,  $n \in \mathbb{N}$ . It follows from (6) that there exists a sequence  $\{x_n\}_{n=1}^\infty \subseteq B$  satisfying

$$|\langle x_n, x'_n \rangle| \geq \delta/2, \quad n \in \mathbb{N}. \quad (8)$$

Since  $|\langle x, x'_n \rangle| \leq \langle |x|, x'_n \rangle$ ,  $x \in E$ , it is clear from (8) that  $\langle |x_n|, x'_n \rangle \geq \delta/2$  for all  $n \in \mathbb{N}$ , with  $\{|x_n|\}_{n=1}^\infty \subseteq B$  (as  $B$  is solid). Accordingly, replacing  $x_n$  by  $|x_n|$ , we may assume that  $\{x_n\}_{n=1}^\infty \subseteq B^+$ . Moreover, since  $\{x'_n\}_{n=1}^\infty$  and  $\{x_n\}_{n=1}^\infty$  are bounded in  $E'_\beta$  and  $E$ , respectively, there exists a constant  $C > 0$  such that  $\langle x_n, x'_n \rangle \leq C$  for all  $n \in \mathbb{N}$ , that is,

$$\delta/2 \leq \langle x_n, x'_n \rangle \leq C, \quad n \in \mathbb{N}.$$

By replacing  $x_n$  with  $(4/\delta)x_n$ ,  $B$  with  $(4/\delta)B$  and  $C$  with  $(4/\delta)C$ , we may assume that the sequence  $\{x_n\}_{n=1}^\infty$  satisfies

$$2 \leq \langle x_n, x'_n \rangle \leq C, \quad n \in \mathbb{N}.$$

Since  $\{x_n\}_{n=1}^\infty$  is bounded, given any continuous Riesz seminorm  $p$  on  $E$ , we have  $\sup_n p(x_n) < \infty$  and hence,  $\sum_{n=1}^\infty p(2^{-n}x_n) < \infty$ . By the sequential completeness of  $E$ , it follows that there exists  $e \in E^+$  such that  $\sum_{n=1}^\infty 2^{-n}x_n = e$ , as a convergent series in  $E$ . Consequently,  $\{x_n\}_{n=1}^\infty$  is contained in the principal ideal  $E_e$  generated by  $e$  in  $E$ . Applying [24], Theorem 2.3.1, to the principal ideal  $E_e$  and the sequences  $\{x_n\}_{n=1}^\infty$  and  $\{x'_n|_{E_e}\}_{n=1}^\infty$ , and passing to a subsequence if necessary, it follows that there exists a pairwise disjoint sequence  $\{v_n\}_{n=1}^\infty$  in  $E^+$  such that

$$0 \leq v_n \leq x_n, \quad \text{and} \quad \langle v_n, x'_n \rangle \geq 1, \quad n \in \mathbb{N}. \quad (9)$$

Since  $B$  is solid, it is clear that  $\{v_n\}_{n=1}^\infty \subseteq B^+$ .

Define the countable set  $A \subseteq (E')^+$  by

$$A = \left\{ \sum_{j=1}^n x'_j : n \in \mathbb{N} \right\}.$$

Since  $A$  is bounded in  $F \cong c_0$ , it is also bounded in  $E'_\beta$ . By hypothesis,  $A$  is then *equicontinuous*. Consequently, there exists a continuous Riesz seminorm  $p_0$  on  $E$  such that

$$|\langle x, x' \rangle| \leq p_0(x), \quad x \in E, \quad x' \in A. \quad (10)$$

Fix  $a = (a_1, \dots, a_n, 0, 0, \dots) \in c_{00}$ . The elements  $\{v_j\}_{j=1}^n$  are pairwise disjoint and so  $\left| \sum_{j=1}^n a_j v_j \right| = \sum_{j=1}^n |a_j| v_j$ . Since  $\sum_{j=1}^n x'_j \in A$ , it follows from (10) and

(9) that

$$\begin{aligned} p_0 \left( \sum_{j=1}^n a_j v_j \right) &= p_0 \left( \sum_{j=1}^n |a_j| v_j \right) \geq \left\langle \sum_{j=1}^n |a_j| v_j, \sum_{k=1}^n x'_k \right\rangle \\ &\geq \sum_{j=1}^n |a_j| \langle v_j, x'_j \rangle \geq \sum_{j=1}^n |a_j| = \|a\|_1. \end{aligned}$$

This shows that

$$\|a\|_1 \leq p_0 \left( \sum_{j=1}^n a_j v_j \right). \quad (11)$$

On the other hand, given any continuous Riesz seminorm  $p$  on  $E$ , we have

$$p \left( \sum_{j=1}^n a_j v_j \right) \leq C_p \|a\|_1, \quad (12)$$

where  $C_p = \sup_{k \in \mathbb{N}} p(v_k) < \infty$ , as  $\{v_k\}_{k=1}^\infty \subseteq B$  is bounded. Estimates (11) and (12) suffice to conclude that the closed Riesz subspace generated by  $\{v_n\}_{n=1}^\infty$  is Riesz homeomorphic to  $\ell_1$ .

The conclusion now follows from Proposition 2.2 (i). ■

For a *Banach space*  $E$  it is a classical result of C. Bessaga and A. Pelczynski that the dual Banach space  $E'_\beta$  contains an isomorphic copy of the Banach space  $c_0$  if and only if  $E$  contains a complemented copy of  $\ell_1$  ([12], p. 48). The extension of this result to *Fréchet spaces* can be found in [7], Lemma 10. The following corollary, which is an immediate consequence of Proposition 2.2 (ii) and Proposition 2.4, may be considered as a lattice version of these results.

**Corollary 2.6** *If  $E$  is a sequentially complete lc-solid Riesz space with the property that countable, bounded subsets of  $E'_\beta$  are equicontinuous, then  $E'_\beta$  contains a lattice copy of  $c_0$  if and only if  $E$  contains a (positively complemented) lattice copy of  $\ell_1$ .*

Corollary 2.6 is known for Banach lattices; see Propositions 2.3.11 and 2.3.12 in [24].

The following simple fact will be required in the sequel. Recall that the topology in a locally solid Riesz space  $E$  is said to be *pre-Lebesgue* whenever every increasing, order bounded sequence in  $E^+$  is Cauchy (see [4], Definition 8.1).

**Lemma 2.7** *Let  $E$  be a lc-solid Riesz space with a pre-Lebesgue topology. If  $\{x'_n\}_{n=1}^\infty$  is an equicontinuous, pairwise disjoint sequence in  $E'$ , then  $x'_n \rightarrow 0$  with respect to  $\sigma(E', E)$ .*

**Proof.** Since  $\{x'_n\}_{n=1}^\infty$  is equicontinuous, there exists a continuous Riesz seminorm  $r$  on  $E$  such that  $|\langle x, x'_n \rangle| \leq r(x)$  for all  $x \in E$  and  $n \in \mathbb{N}$ . Since  $\langle |x|, |x'_n| \rangle = \sup\{|\langle y, x'_n \rangle| : |y| \leq |x|\}$ , the disjoint sequence  $\{|x'_n|\}_{n=1}^\infty$  is also equicontinuous. Therefore, we may assume, without loss of generality, that  $x'_n \geq 0$  for all  $n$ .

Suppose that  $x'_n \not\rightarrow 0$  relative to  $\sigma(E', E)$ , i.e., there exists  $x \in E$  such that  $\langle x, x'_n \rangle \not\rightarrow 0$  as  $n \rightarrow \infty$ . Since  $|\langle x, x'_n \rangle| \leq \langle |x|, x'_n \rangle$ , we may assume that  $x \in E^+$ . By passing to a subsequence, if necessary, there exists  $\delta > 0$  such that  $\langle x, x'_n \rangle \geq \delta$  for all  $n \in \mathbb{N}$ . Since  $\sup_{n \in \mathbb{N}} \langle x, x'_n \rangle \leq r(x) < \infty$ , it follows from [24], Theorem 2.3.1 (applied in the principal ideal  $E_x$ ) that, by passing to a subsequence if

necessary, there exist a pairwise disjoint sequence  $\{v_n\}_{n=1}^\infty$  in  $[0, x]$  and  $\varepsilon > 0$  such that  $\langle v_n, x'_n \rangle \geq \varepsilon$  for all  $n$ . The topology in  $E$  is pre-Lebesgue and so  $v_n \rightarrow 0$  in  $E$  (see [4], Theorem 10.1). In particular,  $r(v_n) \rightarrow 0$  as  $n \rightarrow \infty$ . Since  $\langle v_n, x'_n \rangle \leq r(v_n)$ ,  $n \in \mathbb{N}$ , this yields a contradiction. Therefore, we may conclude that  $\{x'_n\}_{n=1}^\infty$  is a null sequence relative to  $\sigma(E', E)$ . ■

**Remark 2.8** Let  $E$  be a lc-solid Riesz space and suppose that  $F \subseteq E$  is a lattice copy of  $c_0$ . Let  $J : c_0 \rightarrow F$  be a Riesz homeomorphism. For every continuous Riesz seminorm  $p$  on  $E$  there exists a constant  $C_p \geq 0$  such that  $p(J\lambda) \leq C_p \|\lambda\|_\infty$  for  $\lambda \in c_0$ . There also exists a continuous Riesz seminorm  $q$  on  $E$  such that  $\|\lambda\|_\infty \leq q(J\lambda)$  for  $\lambda \in c_0$ . For each  $n \in \mathbb{N}$ , define the positive linear functional  $\varphi_n$  on  $F$  by  $\langle x, \varphi_n \rangle = (J^{-1}x)(n)$ ,  $x \in F$ . Since

$$|\langle x, \varphi_n \rangle| = |(J^{-1}x)(n)| \leq \|J^{-1}x\|_\infty \leq q(x), \quad x \in F,$$

it follows from Theorem 2.1 that, for each  $n \in \mathbb{N}$ , there exists a positive linear functional  $\psi_n$  on  $E$  such that  $\psi_n|_F = \varphi_n$  and  $|\langle x, \psi_n \rangle| \leq q(x)$  for  $x \in E$  (and so,  $0 \leq \psi_n \in E'$ ). If it is possible to choose the functionals  $\psi_n$  ( $n \in \mathbb{N}$ ) such that  $\langle x, \psi_n \rangle \rightarrow 0$  as  $n \rightarrow \infty$  for all  $x \in E$ , then  $F$  is positively complemented in  $E$ . Indeed, if this is the case, then the linear map  $P : E \rightarrow E$  defined by

$$Px = J(\langle x, \psi_n \rangle), \quad x \in E,$$

is easily verified to be a positive continuous projection onto  $F$ .

**Corollary 2.9** *If  $E$  is a lc-solid Riesz space with pre-Lebesgue topology, then any lattice copy of  $c_0$  in  $E$  is positively complemented.*

**Proof.** Suppose that  $F$  is a Riesz subspace of  $E$  for which there exists a Riesz homeomorphism  $J : c_0 \rightarrow F$ . Let the vectors  $e_n \in F$  ( $n \in \mathbb{N}$ ) correspond to the unit basis vectors in  $c_0$ . Using the notation introduced in Remark 2.8, let  $0 \leq x'_n \in E'$  be the minimal positive extension of the restriction of  $\psi_n|_{E_{e_n}}$ . The sequence  $\{x'_n\}_{n=1}^\infty$  is pairwise disjoint and  $x'_n|_F = \varphi_n$  for all  $n$  (cf. the proof of Proposition 2.2 (i)). Since  $|\langle x, x'_n \rangle| \leq \langle |x|, x'_n \rangle \leq \langle |x|, \psi_n \rangle \leq q(x)$  for all  $x \in E$  and  $n \in \mathbb{N}$ , it follows that  $\{x'_n\}_{n=1}^\infty$  is equicontinuous. Hence, Lemma 2.7 applied to the sequence  $\{x'_n\}_{n=1}^\infty$  implies that  $(\langle x, x'_n \rangle) \in c_0$  for all  $x \in E$ . As observed in Remark 2.8, this implies that the map  $P : E \rightarrow E$  given by  $Px = J(\langle x, x'_n \rangle)$ ,  $x \in E$ , is a linear positive continuous projection onto  $F$ . ■

### 3 Proofs of Theorems 1.1 and 1.2

In this section we will present the proofs of Theorems 1.1 and 1.2. Actually, we will prove the results in a more general setting (so that these results also apply to the duals of Fréchet lattices).

For lc-solid Riesz spaces the following characterization of semireflexivity is relevant (see [4], Theorem 22.4). It should be recalled that a lc-solid Riesz space  $E$  has a *Levi topology* (or, has the *Levi property*) if every upwards directed, topologically bounded system in  $E^+$  has a supremum in  $E^+$  ([4], p.61). In this case,  $E$  is necessarily Dedekind complete.

**Proposition 3.1** *If  $E$  is a lc-solid Riesz space, then  $E$  is semireflexive if and only if the topology in  $E$  is both Lebesgue and Levi and the topology in  $E'_\beta$  is Lebesgue.*

Theorem 1.2 is a special case of the following result.

**Proposition 3.2** *Suppose that  $E$  is a lc-solid Riesz space such that:*

- (a)  $E$  is Dedekind  $\sigma$ -complete;
- (b)  $E$  is topologically complete;
- (c) countable bounded subsets of  $E'_\beta$  are equicontinuous.

*The following statements are equivalent.*

- (i)  $E$  is not semireflexive.
- (ii)  $E$  contains a positively complemented lattice copy of  $\ell_\infty$ , or  $c_0$ , or  $\ell_1$ .

**Proof.** Only (i) $\Rightarrow$ (ii) requires a proof. Assuming that  $E$  is not semireflexive, Proposition 3.1 yields three possibilities:

- (I) the topology of  $E$  is not Lebesgue;
- (II) the topology of  $E$  is Lebesgue but, not Levi;
- (III) the topology of  $E'_\beta$  is not Lebesgue.

In case (I) it follows from [4], Theorem 10.3, that the topology of  $E$  is not pre-Lebesgue. Since  $E$  is Dedekind  $\sigma$ -complete, it follows from [4], Theorem 10.7, that  $E$  contains a lattice copy of  $\ell_\infty$ , which is positively complemented by Remark 2.3 (b).

In case (II) it follows from [27], Theorem 1, that  $E$  contains a lattice copy of  $c_0$ . Since the topology in  $E$  is Lebesgue (and hence, pre-Lebesgue; see [4], Theorem 10.3), it follows from Corollary 2.9 that this copy of  $c_0$  is positively complemented.

Finally, consider case (III). Since order intervals in  $E'_\beta$  are always topologically complete ([4], Theorem 19.13), it follows that  $E'_\beta$  does not have the pre-Lebesgue property (an inspection of the proof of [4], Theorem 10.3, shows that topological completeness of order intervals suffices). Since  $E'_\beta$  is Dedekind complete, it follows from [4], Theorem 10.7, that  $E'_\beta$  contains a lattice copy of  $\ell_\infty$  and hence, a lattice copy of  $c_0$ . Proposition 2.4 now implies that  $E$  contains a positively complemented lattice copy of  $\ell_1$ . The proof is complete. ■

Observe that, for cases (I) and (II) in the proof of Proposition 3.2, condition (c) on the space  $E$  is not required.

Before proving our next result, the following observations will be useful. A lcHs  $E$  is semireflexive if and only if every bounded subset of  $E$  is relatively  $\sigma(E, E')$ -compact (see [22], Proposition 23.18). In particular, if  $E$  is semireflexive, then every bounded sequence  $\{x_n\}_{n=1}^\infty$  in  $E$  has a  $\sigma(E, E')$ -cluster point (that is, there exists  $y \in E$  such that every  $\sigma(E, E')$ -neighbourhood of  $y$  contains  $x_n$  for infinitely many values of  $n$ ). If  $T \in \mathcal{L}(E)$  is power bounded and  $x \in E$ , then it follows via an argument analogous to the one used in

the proof of [20], Chapter 2, Theorem 1.1 (replacing the norm by seminorms), that  $\lim_{n \rightarrow \infty} T_{[n]}x$  exists in  $E$  if and only if the sequence  $\{T_{[n]}x\}_{n=1}^{\infty}$  has a  $\sigma(E, E')$ -cluster point in  $E$  (where  $T_{[n]}$  is defined by (5)). Since  $\{T^n\}_{n=1}^{\infty}$  is equicontinuous, for each  $x \in E$  the set  $\{T_{[n]}x : n \in \mathbb{N}\}$  is bounded in  $E$ . Consequently, if  $E$  is semireflexive, then for all  $x \in E$  the sequence  $\{T_{[n]}x\}_{n=1}^{\infty}$  has a  $\sigma(E, E')$ -cluster point in  $E$  and so,  $\lim_{n \rightarrow \infty} T_{[n]}x$  exists in  $E$ . This establishes the following result.

**Proposition 3.3** *Every semireflexive lcHs is mean ergodic.*

**Remark 3.4** (a) Proposition 3.3 improves Proposition 2.3 of [2], where the assumptions on the lcHs  $E$  are that it should be reflexive and have the property that relatively  $\sigma(E, E')$ -compact sets are relatively sequentially  $\sigma(E, E')$ -compact (in which case  $E$  is mean ergodic). Accordingly, several other results in [2], namely Proposition 2.4 and Theorems 3.5 and 3.7, can also be extended by removing the requirement that "relatively  $\sigma(E, E')$ -compact sets are relatively sequentially  $\sigma(E, E')$ -compact" and replacing the use of Proposition 2.3 of [2] in their proofs with Proposition 3.3 above.

(b) Suppose that  $E$  is a lcHs and  $F$  is a closed complemented subspace of  $E$  (that is,  $F$  is the range of a continuous projection  $P$  in  $E$ ). Let  $T \in \mathcal{L}(F)$ . Considering  $TP$  as a continuous operator from  $E$  into itself, it is clear that  $(TP)^n = T^n P$  and  $(TP)_{[n]} = T_{[n]} P$  for all  $n \in \mathbb{N}$ . Evidently, the operator  $TP$  is power bounded in  $E$  whenever  $T$  is power bounded in  $F$ . Moreover, if  $T$  is not mean ergodic in  $F$ , then  $TP$  is not mean ergodic in  $E$ . Note that, if  $E$  is a lc-solid Riesz space and  $F$  is a Riesz subspace, then  $TP$  is positive whenever both  $T$  and  $P$  are positive.

**Proposition 3.5** *Let  $E$  be a lc-solid Riesz space satisfying conditions (a), (b) and (c) of Proposition 3.2. The following statements are equivalent.*

- (i)  $E$  is semireflexive.
- (ii)  $E$  is mean ergodic.
- (iii) Every positive power bounded linear operator in  $E$  is mean ergodic.

**Proof.** Implication (i) $\Rightarrow$ (ii) is Proposition 3.3 and (ii) $\Rightarrow$ (iii) is trivial. To show that (iii) $\Rightarrow$ (i), suppose that  $E$  is *not* semireflexive. It follows from Proposition 3.2 that  $E$  contains a positively complemented lattice copy  $F$  of  $\ell_{\infty}$ , or  $c_0$ , or  $\ell_1$ . As observed before (see (4)), there then exists a *positive* power bounded linear operator  $T$  in  $F$  which is not mean ergodic. Via Remark 3.4 (b), this implies that  $E$  does not satisfy statement (iii). The proof is complete. ■

To treat the case where the space  $E$  is not Dedekind  $\sigma$ -complete, the following result will be needed. In [1], Theorem 1.6, it is shown that if a Fréchet space  $E$  contains a copy of the Banach space  $c_0$ , then  $E$  is not mean ergodic. The same conclusion holds in any sequentially complete lcHs  $E$ ; see [2], Theorem 3.8. The next proposition exhibits a similar result for lc-solid Riesz spaces, without any sequential completeness requirement. The proof of this result uses some ideas from the proof of [14], Proposition 1.

**Proposition 3.6** *Suppose that  $E$  is a lc-solid Riesz space. If  $E$  contains a lattice copy of  $c_0$ , then there exists a regular power bounded operator on  $E$  which is not mean ergodic. In particular,  $E$  is not mean ergodic.*

**Proof.** Suppose that  $F$  is a lattice copy of  $c_0$  in  $E$  and let  $J : c_0 \rightarrow F$  be a Riesz homeomorphism. Let the vectors  $\{u_n\}_{n=1}^\infty \subseteq F$  correspond to the unit basis vectors in  $c_0$ , so that

$$J(\lambda) = \sum_{n=1}^{\infty} \lambda_n u_n, \quad \lambda = (\lambda_n) \in c_0.$$

Since  $J$  is a linear homeomorphism, there exists a continuous Riesz seminorm  $q$  on  $E$  such that

$$\|\lambda\|_\infty \leq q(J\lambda), \quad \lambda \in c_0. \quad (13)$$

Moreover, for every continuous Riesz seminorm  $p$  on  $E$  there exists a constant  $C_p \geq 0$  such that

$$p(J\lambda) \leq C_p \|\lambda\|_\infty, \quad \lambda \in c_0. \quad (14)$$

For  $n \in \mathbb{N}$ , define the linear functional  $0 \leq \varphi_n \in F'$  by

$$\langle x, \varphi_n \rangle = (J^{-1}x)(n), \quad x \in F.$$

It follows from (13) that

$$|\langle x, \varphi_n \rangle| \leq \|J^{-1}x\|_\infty \leq q(x), \quad x \in F,$$

and so Theorem 2.1 implies that there exists  $0 \leq \psi_n \in E^\sim$  such that  $\psi_n|_F = \varphi_n$  and  $|\langle x, \psi_n \rangle| \leq q(x)$  for  $x \in E$  (so, in particular,  $\psi_n \in E'$ ). If  $\langle x, \psi_n \rangle \rightarrow 0$  as  $n \rightarrow \infty$  for all  $x \in E$ , then  $F$  is positively complemented in  $E$  (see Remark 2.8), in which case it follows that there exists a positive power bounded operator on  $E$  which is not mean ergodic (see the proof of Proposition 3.5). In this case we are done.

So, assume that there exists  $0 < u \in E$  such that  $\langle u, \psi_n \rangle \not\rightarrow 0$  as  $n \rightarrow \infty$ . Fix a sequence  $\{\alpha_n\}_{n=1}^\infty$  in  $\mathbb{R}$  satisfying  $0 < \alpha_n < 1$  for all  $n$  with  $\alpha_n \rightarrow 0$  as  $n \rightarrow \infty$ . Define the positive linear operator  $B_1 : E \rightarrow E$  by

$$B_1x = J((\alpha_n \langle x, \psi_n \rangle)) = \sum_{n=1}^{\infty} \alpha_n \langle x, \psi_n \rangle u_n, \quad x \in E. \quad (15)$$

Note that  $B_1$  is well defined as  $|\langle x, \psi_n \rangle| \leq q(x)$  for all  $n \in \mathbb{N}$  implies that  $(\alpha_n \langle x, \psi_n \rangle) \in c_0$  for all  $x \in E$ . If  $p$  is any continuous Riesz seminorm on  $E$ , then it follows from (14) that

$$p(B_1x) \leq C_p \|(\alpha_n \langle x, \psi_n \rangle)\|_\infty \leq C_p \|(\langle x, \psi_n \rangle)\|_\infty \leq C_p q(x), \quad x \in E,$$

and so  $B_1$  is continuous. Define the regular operator  $T \in \mathcal{L}(E)$  by  $T = I - B_1$ . Using (15) and the identities  $\langle u_n, \psi_k \rangle = \delta_{kn}$  for all  $k, n \in \mathbb{N}$ , it follows that  $T^k = I - B_k$ , where

$$B_kx = \sum_{n=1}^{\infty} \beta_n^{(k)} \langle x, \psi_n \rangle u_n, \quad x \in E, \quad (16)$$

and  $\beta_n^{(k)} = 1 - (1 - \alpha_n)^k$  for all  $k, n \in \mathbb{N}$ . Observe that  $0 \leq \beta_n^{(k)} \uparrow_k 1$  for all  $n$  and that

$$0 \leq B_1 \leq B_2 \leq \dots \quad (17)$$

Furthermore, if  $p$  is any continuous Riesz seminorm on  $E$ , then

$$\begin{aligned} p(T^k x) &\leq p(x) + p(B_k x) \leq p(x) + C_p \left\| \left( \beta_n^{(k)} \langle x, \psi_n \rangle \right) \right\|_\infty \\ &\leq p(x) + C_p \|(\langle x, \psi_n \rangle)\|_\infty \leq p(x) + C_p q(x) \end{aligned}$$

for all  $x \in E$  and  $k \in \mathbb{N}$ . Hence, the operator  $T$  is power bounded. Defining  $S_n = n^{-1}(B_1 + \dots + B_n)$ , it is clear that

$$T_{[n]} = I - S_n, \quad n \in \mathbb{N},$$

and  $0 \leq S_1 \leq S_2 \leq \dots$ . Hence, if  $x \in E$ , then  $\lim_{n \rightarrow \infty} T_{[n]}x$  exists if and only if  $\lim_{n \rightarrow \infty} S_n x$  exists.

Suppose that  $0 \leq x \in E$  is such that  $y = \lim_{n \rightarrow \infty} S_n x$  exists (in which case  $S_n x \uparrow_n y$ ; [4], Theorem 5.6 (iii)). Using (17) and the fact that any *increasing* Cesàro convergent sequence is itself convergent, it follows that  $B_n x \rightarrow y$  as  $n \rightarrow \infty$  (and so  $0 \leq B_n x \uparrow_n y$ ). Observe that

$$\begin{aligned} y &= \bigvee_{k=1}^{\infty} B_k x = \bigvee_{k=1}^{\infty} \bigvee_{n=1}^{\infty} \beta_n^{(k)} \langle x, \psi_n \rangle u_n \\ &= \bigvee_{n=1}^{\infty} \bigvee_{k=1}^{\infty} \beta_n^{(k)} \langle x, \psi_n \rangle u_n = \bigvee_{n=1}^{\infty} \langle x, \psi_n \rangle u_n. \end{aligned}$$

On the other hand,  $B_n x \in F^+$  for all  $n$  and so  $y \in F^+$ . Hence, there exists  $\lambda = (\lambda_n) \in c_0^+$  such that  $y = J\lambda = \bigvee_{n=1}^{\infty} \lambda_n u_n$  and so,  $\bigvee_{n=1}^{\infty} \langle x, \psi_n \rangle u_n = \bigvee_{n=1}^{\infty} \lambda_n u_n$ . Since  $\{u_n\}_{n=1}^{\infty}$  is a disjoint sequence, it follows that  $\langle x, \psi_n \rangle = \lambda_n$  for all  $n$  and hence,  $(\langle x, \psi_n \rangle) \in c_0$ .

We thus have shown that if  $0 \leq x \in E$  is such that  $\lim_{n \rightarrow \infty} T_{[n]}x$  exists, then  $(\langle x, \psi_n \rangle) \in c_0$ . Since we assumed that there exists  $0 < u \in E$  such that  $\langle u, \psi_n \rangle \not\rightarrow 0$  as  $n \rightarrow \infty$ , this shows that the regular power bounded operator  $T$  is not mean ergodic. The proof is complete. ■

As observed in [27], Lemma 1, any sequentially complete lc-solid Riesz space which is not Dedekind  $\sigma$ -complete contains a lattice copy of  $c_0$ . Together with Proposition 3.6, this yields the following result.

**Corollary 3.7** *If  $E$  is a sequentially complete lc-solid Riesz space which is mean ergodic, then  $E$  is Dedekind  $\sigma$ -complete.*

In combination with Propositions 3.3 and 3.5 we obtain the following consequence.

**Corollary 3.8** *If  $E$  is a topologically complete lc-solid Riesz space such that countable bounded subsets of  $E'_\beta$  are equicontinuous, then the following statements are equivalent.*

- (i)  $E$  is semireflexive.
- (ii)  $E$  is mean ergodic.

(iii)  $E$  is Dedekind  $\sigma$ -complete and every positive power bounded linear operator in  $E$  is mean ergodic.

The proof of Theorem 1.1 is now a simple consequence of the previous results.

**Proof.** (of Theorem 1.1) Let  $E$  be a Fréchet lattice. The equivalence of statements (i), (ii) and (iii) is a special case of Corollary 3.8. The strong dual  $E'_\beta$  of  $E$  is a topologically complete and Dedekind complete lc-solid Riesz space for which countable bounded subsets of  $(E'_\beta)'_\beta$  are equicontinuous (see the discussion prior to Theorem 2.1 and Remark 2.5 (i)). Consequently, Proposition 3.5 may be applied to  $E'_\beta$  and so (iv) holds if and only if  $E'_\beta$  is semireflexive.

If  $E$  is reflexive, then  $E'_\beta$  is reflexive (see [22], Corollary 25.11) and hence, semireflexive. Assume now that  $E'_\beta$  is semireflexive. Since  $E$  is a Fréchet space, its topology coincides with the Mackey topology ([19], p. 261, (4)). Since  $E$  is complete, it follows from [19], p. 303, (6), that  $E$  is reflexive. This shows that statements (iv) and (i) in Theorem 1.1 are equivalent. The proof is complete. ■

**Remark 3.9** Let  $E$  be a topologically complete lc-solid Riesz space. If  $E$  is mean ergodic, then it follows from Corollary 3.7 and the proof of Proposition 3.2 that  $E$  has both the Lebesgue and the Levi property. In particular,  $E$  is Dedekind complete.

## 4 Proof of Theorem 1.3

Recall that a linear map  $T$  on a Riesz space  $E$  is called power order bounded if for every  $x \in E^+$  there exists  $z \in E^+$  such that

$$\bigcup_{n=0}^{\infty} T^n([-x, x]) \subseteq [-z, z]. \quad (18)$$

Note that (18) is equivalent to saying that  $|T^n y| \leq z$  for all  $n = 0, 1, \dots$  whenever  $|y| \leq x$ .

**Proposition 4.1** *If  $E$  is a complete barrelled lc-solid Riesz space, then the following statements are equivalent.*

- (i) *The topology of  $E$  is Lebesgue.*
- (ii) *Every power order bounded operator on  $E$  is mean ergodic.*

**Proof.** (i) $\Rightarrow$ (ii). Let  $T$  be a power order bounded operator in  $E$ . As observed in Section 1, this implies that  $T$  is power bounded (as  $E$  is assumed to be barrelled). Given  $x \in E$ , let  $z \in E^+$  satisfy (18) for  $|x|$ , which implies, in particular, that  $|T^n x| \leq z$  for all  $n \in \mathbb{N}$ . Consequently,  $|T_{[n]} x| \leq z$  for all  $n \in \mathbb{N}$ , that is, the sequence  $\{T_{[n]} x\}_{n=1}^{\infty}$  is contained in the order interval  $[-z, z]$ . Since  $E$  is topologically complete and its topology is Lebesgue, it follows that  $E$  is Dedekind complete (see [4], Theorem 10.3). Hence, by [4], Theorem 22.1, the order interval  $[-z, z]$  is  $\sigma(E, E')$ -compact and so, the set  $\{T_{[n]} x : n \in \mathbb{N}\}$  is relatively  $\sigma(E, E')$ -compact. Therefore, the sequence  $\{T_{[n]} x\}_{n=1}^{\infty}$  has a  $\sigma(E, E')$  cluster point in  $E$ , which implies that  $\lim_{n \rightarrow \infty} T_{[n]} x$  exists in  $E$  (see the discussion prior to Proposition 3.3). Hence,  $T$  is mean ergodic.

(ii) $\Rightarrow$ (i). Suppose that the topology in  $E$  is not Lebesgue. Since  $E$  is complete it follows from [4], Theorem 10.3, that the topology is not pre-Lebesgue. Therefore, there exist  $0 < u \in E$  and a disjoint sequence  $\{u_n\}_{n=1}^\infty$  in  $[0, u]$  such that  $u_n \rightarrow 0$  as  $n \rightarrow \infty$  ([4], Theorem 10.1). Hence, there exists a continuous Riesz seminorm  $r$  on  $E$  such that  $r(u_n) \rightarrow 0$  as  $n \rightarrow \infty$ . By passing to a subsequence, if necessary, we may assume that  $r(u_n) \geq \delta$  for all  $n$  and some  $\delta > 0$ . Define the injective Riesz homomorphism  $J_0 : c_{00} \rightarrow E$  by

$$J_0\lambda = \sum_{k=1}^n \lambda_k u_k, \quad \lambda = (\lambda_1, \dots, \lambda_n, 0, 0, \dots) \in c_{00}.$$

Since  $\|J_0\lambda\| \leq \|\lambda\|_\infty \|u\|$ , it follows that  $p(J_0\lambda) \leq p(u) \|\lambda\|_\infty$ ,  $\lambda \in c_{00}$ , for all continuous Riesz seminorms  $p$  on  $E$ . The inequalities  $\|J_0\lambda\| \geq |\lambda_k| \|u_k\|$  for all  $k$ , imply that  $r(J_0\lambda) \geq \delta \|\lambda\|_\infty$ . Since  $E$  is complete, it follows that  $J_0$  extends continuously to a Riesz homeomorphism  $J$  from  $c_0$  onto a closed Riesz subspace  $F$  of  $E$  satisfying  $p(J\lambda) \leq p(u) \|\lambda\|_\infty$ ,  $\lambda \in c_0$ , for all continuous Riesz seminorms  $p$  on  $E$ . Moreover,  $\|\lambda\|_\infty \leq q(J\lambda)$  for  $\lambda \in c_0$ , where  $q = \delta^{-1}r$ . Consequently, we are in the situation of Proposition 3.6. Let  $\{\psi_n\}_{n=1}^\infty$  be the sequence in  $(E')^+$  as defined in the proof of Proposition 3.6 and observe that  $\langle u, \psi_n \rangle \geq \langle u_n, \psi_n \rangle = 1$  for all  $n$ . Therefore, if we define  $T = I - B_1$ , where the positive linear operator  $B_1$  is given by (15), then  $T$  is power bounded but not mean ergodic (see the proof of Proposition 3.6).

We claim that  $T$  is power order bounded. Recall that  $T^k = I - B_k$ ,  $k \in \mathbb{N}$ , where the positive operators  $B_k$  are given by (16). Let  $x \in E^+$  and  $y \in E$  satisfy  $|y| \leq x$ . Using  $0 \leq \langle x, \psi_n \rangle \leq q(x)$  for all  $n$ , it follows easily that

$$\|T^k y\| \leq \|y\| + \|B_k y\| \leq \|x\| + \|B_k x\| \leq \|x\| + q(x) \|u\|, \quad k \in \mathbb{N},$$

which establishes the claim. We thus have shown that if the topology of  $E$  is not Lebesgue, then there exists a power order bounded operator on  $E$  which is not mean ergodic. The proof is complete. ■

Since Fréchet lattices are complete barrelled lc-solid Riesz spaces, Theorem 1.3 is a special case of Proposition 4.1.

## 5 Uniform mean ergodicity

Recall that a power bounded linear operator  $T \in \mathcal{L}(E)$ , with  $E$  a lch, is called *uniformly mean ergodic* if the Cesàro means  $T_{[n]}$ ,  $n \in \mathbb{N}$ , (as defined by (5)) are convergent in  $\mathcal{L}(E)$  with respect to the *uniform operator topology*  $\tau_b$  (defined via the seminorms  $q_B$  in  $\mathcal{L}(E)$  given by (3)). If  $E$  is a lc-solid Riesz space, then the topology  $\tau_b$  is generated by the seminorms  $q_B$ , where  $q$  is a continuous Riesz seminorm on  $E$  and  $B \in \mathcal{B}_s$ .

In the sequel, we denote by  $Z(E)$  the *centre* of a lc-solid Riesz space  $E$  (see [29], Chapter 20, or [24], Section 3.1). The Boolean algebra  $\mathcal{P}(E)$  of all band projections in  $E$  (cf. [21], Section 30) coincides with the Boolean algebra of all idempotents in  $Z(E)$  (equivalently, the Boolean algebra of all components of the identity operator  $I$  in  $Z(E)$ ). If  $T \in Z(E)$ , then, by definition, there exists  $0 \leq \lambda \in \mathbb{R}$  such that  $|Tx| \leq \lambda|x|$ ,  $x \in E$ , and so  $Z(E) \subseteq \mathcal{L}(E)$ . Furthermore,  $Z(E)$  is a commutative subalgebra of  $\mathcal{L}(E)$  and  $Z(E)$  is an  $f$ -algebra (see e.g.

[24], Section 3.1 or [29], Section 140, for the definition). If  $q$  is a continuous Riesz seminorm on  $E$  and  $B \in \mathcal{B}_s$ , then  $q_B$  is a Riesz seminorm on  $Z(E)$ . Indeed, if  $|S| \leq |T|$  in  $Z(E)$ , then  $|Sx| = |S||x| \leq |T||x| = |Tx|$  and hence,  $q(Sx) \leq q(Tx)$  for all  $x \in E$ , which implies that  $q_B(S) \leq q_B(T)$ . Consequently, equipped with the topology  $\tau_b$ ,  $Z(E)$  is a lc-solid Riesz space. It should also be observed that an operator  $T \in Z(E)$  is power bounded if and only if  $|T| \leq I$ .

**Theorem 5.1** *If  $E$  is a Dedekind  $\sigma$ -complete lc-solid Riesz space in which order intervals are topologically complete, then the following statements are equivalent.*

- (i) *Every power bounded  $T \in Z(E)$  is uniformly mean ergodic.*
- (ii) *Every topologically bounded, disjoint sequence in  $E$  converges to zero.*
- (iii) *Every disjoint sequence of band projections in  $E$  converges to zero with respect to  $\tau_b$ .*
- (iv)  *$\mathcal{P}(E)$  is a  $\tau_b$ -Bade complete Boolean algebra of projections, that is,  $\mathcal{P}(E)$  is a complete Boolean algebra and  $P_\alpha \uparrow_\alpha P$  in  $\mathcal{P}(E)$  implies that  $P_\alpha \rightarrow_\alpha P$  with respect to  $\tau_b$ .*

**Proof.** (i) $\Rightarrow$ (ii). Suppose that  $\{u_n\}_{n=1}^\infty$  is a topologically bounded, disjoint sequence in  $E^+$ . Let  $P_n$  denote the band projection in  $E$  onto the principal band  $\{u_n\}^{dd}$  generated by  $u_n$  (recall that a Dedekind  $\sigma$ -complete Riesz space has the principal projection property; see [21], Section 25) and observe that  $P_m P_n = 0$  whenever  $m \neq n$ . Fix a sequence  $\{\alpha_n\}_{n=1}^\infty$  in  $\mathbb{R}$  satisfying  $0 < \alpha_n < 1$  for all  $n$  and  $\alpha_n \uparrow_n 1$ . If  $x \in E^+$ , then

$$0 \leq \sum_{n=1}^N \alpha_n P_n x \uparrow_N x$$

and so,  $Tx = \sum_{n=1}^\infty \alpha_n P_n x = \sup_N \sum_{n=1}^N \alpha_n P_n x$  exists in  $E$  (as  $E$  is Dedekind  $\sigma$ -complete). Consequently,

$$Tx = \sum_{n=1}^\infty \alpha_n P_n x, \quad x \in E,$$

exists as an order convergent series in  $E$ . Since  $0 \leq T \leq I$ , it is clear that  $T \in Z(E) \subseteq \mathcal{L}(E)$  and  $T$  is power bounded. It is easily verified that

$$T^k x = \sum_{n=1}^\infty \alpha_n^k P_n x, \quad x \in E, \tag{19}$$

for all  $k \in \mathbb{N}$ . Note that  $0 \leq T^k \downarrow_k 0$ . We claim that  $T^k x \downarrow_k 0$  in  $E$  for all  $x \in E^+$ . Indeed, suppose that  $w \in E$  is such that  $0 \leq w \leq T^k x$  for all  $k \in \mathbb{N}$  and some  $x \in E^+$ . It follows from (19) that  $0 \leq P_n w \leq \alpha_n^k P_n x$  for all  $k, n \in \mathbb{N}$  and so,  $P_n w = 0$  for all  $n$  (as  $\alpha_n^k \downarrow_k 0$ ). This implies that  $w \wedge P_n x = 0$  for all  $n$ , so  $w = w \wedge Tx = 0$ , which proves the claim.

It is now easy to see that  $0 \leq T_{[k]} x \downarrow_k 0$  for all  $x \in E^+$ . By hypothesis, there exists  $S \in \mathcal{L}(E)$  such that  $T_{[k]} \rightarrow S$  with respect to  $\tau_b$  and so, in particular,  $T_{[k]} x \rightarrow Sx$  for all  $x \in E^+$ . Via [4], Theorem 5.6 (iii), it follows that  $Sx = 0$

for all  $x \in E^+$  and hence,  $S = 0$ . Consequently,  $T_{[k]} \rightarrow 0$  with respect to  $\tau_b$ . Since  $0 \leq T^k \leq T^j$  ( $1 \leq j \leq k$ ), it follows that  $0 \leq T^k \leq T_{[k]}$  and so,  $q_B(T^k) \leq q_B(T_{[k]})$  for every continuous Riesz seminorm  $q$  and every  $B \in \mathcal{B}_s$ . Consequently,  $T^k \rightarrow 0$  with respect to  $\tau_b$ . This implies, in particular, that  $\lim_{k \rightarrow \infty} \sup_n p(T^k u_n) = 0$  for every continuous Riesz seminorm  $p$  on  $E$ . Since  $T^k u_n = \alpha_n^k u_n$ , it follows that  $\lim_{k \rightarrow \infty} \sup_n \alpha_n^k p(u_n) = 0$ . Given  $k \in \mathbb{N}$ , there exists  $N_k \in \mathbb{N}$  such that  $\alpha_n^k \geq 1/2$  for all  $n \geq N_k$  and so,  $\sup_n \alpha_n^k p(u_n) \geq 2^{-1} \sup_{n \geq N_k} p(u_n)$ . Therefore,  $p(u_n) \rightarrow 0$  as  $n \rightarrow \infty$ , which shows that  $u_n \rightarrow 0$  as  $n \rightarrow \infty$  in  $E$ . If  $\{x_n\}_{n=1}^\infty \subseteq E$  is any topologically bounded, disjoint sequence, then  $\{|x_n|\}_{n=1}^\infty$  has the same properties and so  $|x_n| \rightarrow 0$ , which implies that  $x_n \rightarrow 0$  as  $n \rightarrow \infty$ .

(ii) $\Rightarrow$ (iii). Let  $\{P_n\}_{n=1}^\infty$  be a disjoint sequence in  $\mathcal{P}(E)$  and suppose that  $P_n \rightarrow 0$  with respect to  $\tau_b$ . Then there exists a continuous Riesz seminorm  $q$  on  $E$  and  $B \in \mathcal{B}_s$  such that  $q_B(P_n) \rightarrow 0$  as  $n \rightarrow \infty$  (with  $q_B$  given by (3)). By passing to a subsequence, if necessary, we may assume that  $q_B(P_n) \geq \delta$  for all  $n \in \mathbb{N}$  and some  $\delta > 0$ . Hence, for each  $n$  there exists  $x_n \in B$  such that  $q(P_n x_n) \geq \delta/2$ . Since  $|P_n x_n| = P_n |x_n| \leq |x_n|$ , the sequence  $\{P_n x_n\}_{n=1}^\infty$  is bounded and disjoint and so, by hypothesis,  $P_n x_n \rightarrow 0$  as  $n \rightarrow \infty$ . This contradicts the fact that  $q(P_n x_n) \geq \delta/2$  for all  $n$ . Hence, we may conclude that  $P_n \rightarrow 0$  with respect to  $\tau_b$ .

(iii) $\Rightarrow$ (iv). First, observe that the topology in  $E$  is pre-Lebesgue. Indeed, suppose that  $x \in E^+$  and that  $\{x_n\}_{n=1}^\infty$  is a disjoint sequence in  $[0, x]$ . Denoting by  $P_n$  the band projection in  $E$  onto the principal band  $\{x_n\}^{dd}$ , it is clear that  $\{P_n\}_{n=1}^\infty$  is a disjoint sequence in  $\mathcal{P}(E)$  and so, by hypothesis,  $P_n \rightarrow 0$  as  $n \rightarrow \infty$  with respect to  $\tau_b$ . Since  $0 \leq x_n = P_n x_n \leq P_n x$  for all  $n$ , it is now clear that  $x_n \rightarrow 0$  as  $n \rightarrow \infty$ . Hence, the topology of  $E$  is pre-Lebesgue. Since, by hypothesis, order intervals in  $E$  are complete, this implies that  $E$  has the Lebesgue property and  $E$  is Dedekind complete (see [4], Theorem 10.3, and its proof, where it is only required that order intervals are complete). Consequently,  $\mathcal{P}(E)$  is a complete Boolean algebra (see [21], Theorem 24.9 (i) and Theorem 30.6 (ii)).

We shall show next that  $\tau_b$  is a pre-Lebesgue topology on  $Z(E)$ . Since  $I$  is a strong order unit in  $Z(E)$ , it suffices to show that any disjoint sequence  $\{T_n\}_{n=1}^\infty$  in  $[0, I]$  converges to zero with respect to  $\tau_b$ . Denoting by  $P_n \in \mathcal{P}(E)$  the component of  $I$  in the principal band  $\{T_n\}^{dd}$ , it follows that  $\{P_n\}_{n=1}^\infty$  is a disjoint sequence in  $\mathcal{P}(E)$  satisfying  $0 \leq T_n = T_n P_n \leq P_n$  for all  $n$ . By hypothesis,  $P_n \rightarrow 0$  and so also  $T_n \rightarrow 0$  as  $n \rightarrow \infty$  with respect to  $\tau_b$ . Hence,  $\tau_b$  is a pre-Lebesgue topology on  $Z(E)$ . Since order intervals in  $E$  are complete, it is easily verified that order intervals in  $Z(E)$  are complete with respect to  $\tau_b$ . Consequently,  $\tau_b$  is a Lebesgue topology on  $Z(E)$ . In particular, if  $P_\alpha \uparrow_\alpha P$  in  $\mathcal{P}(E)$ , then  $P_\alpha \rightarrow_\alpha P$  with respect to  $\tau_b$ . We may conclude that  $\mathcal{P}(E)$  is  $\tau_b$ -Bade complete.

(iv) $\Rightarrow$ (i). We start with the following simple observation. If  $T \in Z(E)$  satisfies  $-I \leq T \leq \alpha I$  for some  $\alpha < 1$ , then  $T_{[k]} \rightarrow 0$  as  $k \rightarrow \infty$  with respect to  $\tau_b$ . Indeed,  $I - T \geq (1 - \alpha)I$  and so  $(I - T)^{-1}$  exists in  $Z(E)^+$  (see [29], Theorem 146.3). This implies that

$$T + T^2 + \dots + T^k = (I - T)^{-1} (T - T^{k+1})$$

and so,

$$|T_{[k]}| \leq (1/k) (I - T)^{-1} (|T| + |T|^{k+1}) \leq (2/k) (I - T)^{-1}$$

for all  $k \in \mathbb{N}$ . From this estimate it is clear that  $T_{[k]} \rightarrow 0$  with respect to  $\tau_b$ .

Let  $T \in Z(E)$  satisfy  $|T| \leq I$  and fix  $0 < \alpha < 1$ . Let  $P \in \mathcal{P}(E)$  be the component of  $I$  in the band  $\left\{ (I - T)^+ \right\}^d$ , in which case  $PT \leq P$ . On the other hand, since  $(P - PT)^+ = P(I - T)^+ = 0$ , it follows that  $P \leq PT$  and hence,  $P = PT$ . This implies, in particular, that  $PT_{[k]} = P$  for all  $k \in \mathbb{N}$  (as  $T$  and  $P$  commute). Let  $Q_\alpha \in \mathcal{P}(E)$  be the component of  $I$  in the band  $\left\{ (\alpha I - T)^+ \right\}^{dd}$ . Note that  $(\alpha I - T)^+ \leq (I - T)^+$  and so,  $PQ_\alpha = 0$ . Since  $(\alpha Q_\alpha - Q_\alpha T)^- = Q_\alpha(\alpha I - T)^- = 0$ , it follows that  $Q_\alpha T \leq \alpha Q_\alpha$  and so  $-I \leq Q_\alpha T \leq \alpha I$ . The previous paragraph implies that  $Q_\alpha T_{[k]} = (Q_\alpha T)_{[k]} \rightarrow 0$  as  $k \rightarrow \infty$  with respect to  $\tau_b$ . Writing

$$T_{[k]} - P = (I - P)T_{[k]} = Q_\alpha T_{[k]} + (I - P - Q_\alpha)T_{[k]},$$

it follows that

$$\limsup_{k \rightarrow \infty} q_B (T_{[k]} - P) \leq \limsup_{k \rightarrow \infty} q_B ((I - P - Q_\alpha)T_{[k]})$$

whenever  $q$  is a continuous Riesz seminorm on  $E$  and  $B \in \mathcal{B}_s$ . Furthermore,  $|T| \leq I$  yields  $|T_{[k]}| \leq I$  and hence,  $|(I - P - Q_\alpha)T_{[k]}| \leq I - P - Q_\alpha$ . So,  $q_B((I - P - Q_\alpha)T_{[k]}) \leq q_B(I - P - Q_\alpha)$  for all  $k$ . Accordingly,

$$\limsup_{k \rightarrow \infty} q_B (T_{[k]} - P) \leq q_B (I - P - Q_\alpha).$$

Now observe that  $I - P - Q_\alpha$  is the component of  $I$  in the band  $\left\{ (\alpha I - T)^+ \right\}^d \cap \left\{ (I - T)^+ \right\}^{dd}$ . Furthermore, if  $\alpha \uparrow 1$ , then  $\left\{ (\alpha I - T)^+ \right\}^{dd} \uparrow \left\{ (I - T)^+ \right\}^{dd}$  and so,  $\left\{ (\alpha I - T)^+ \right\}^d \downarrow \left\{ (I - T)^+ \right\}^d$ . Consequently,  $I - P - Q_\alpha \downarrow 0$  as  $\alpha \uparrow 1$ . By the  $\tau_b$ -Bade completeness of  $\mathcal{P}(E)$ , this implies that  $q_B(I - P - Q_\alpha) \downarrow 0$  as  $\alpha \uparrow 1$  and so we may conclude that  $\lim_{k \rightarrow \infty} q_B(T_{[k]} - P) = 0$ . This shows that  $T_{[k]} \rightarrow P$  as  $k \rightarrow \infty$  with respect to  $\tau_b$ . The proof is complete. ■

**Remark 5.2** If  $E$  is a lc-solid Riesz space, then  $E'_\beta$  is always Dedekind complete (see Section 2) and order intervals in  $E'_\beta$  are topologically complete ([4], Theorem 19.13). Consequently, Theorem 5.1 may always be applied in  $E'_\beta$ .

An immediate consequence of the above theorem is the following result.

**Corollary 5.3** *If  $E$  is topologically complete lc-solid Riesz space which is uniformly mean ergodic, then every topologically bounded, disjoint sequence in  $E$  converges to zero.*

**Proof.** Since  $E$  is, in particular, mean ergodic, it follows that  $E$  is Dedekind complete (see Remark 3.9) and so, Theorem 5.1 applies. ■

*Theorem 1.4 follows immediately from Corollary 5.3.* Indeed, if in a Banach lattice every norm bounded, disjoint sequence converges to zero, then every disjoint system in  $E$  must be finite. This implies that  $E$  is finite dimensional (see [21], Theorem 26.10).

It should be observed that any lcHs  $E$  in which bounded sets are relatively compact is necessarily uniformly mean ergodic. Indeed, bounded subsets of  $E$  are, in particular, relatively weakly compact and so,  $E$  is semireflexive. This implies that  $E$  is mean ergodic (see Proposition 3.3). Now, if  $T \in \mathcal{L}(E)$  is power bounded, then the sequence  $\{T_{[k]}\}_{k=1}^{\infty}$  is equicontinuous and convergent in  $\mathcal{L}_s(E)$ . Accordingly, the sequence  $\{T_{[k]}\}_{k=1}^{\infty}$  also converges uniformly on all relatively compact subsets and hence, on all bounded subsets of  $E$ , that is, in  $\mathcal{L}_b(E)$ . Therefore,  $E$  is uniformly mean ergodic.

If  $E$  is a *discrete* and complete lc-solid Riesz space in which every bounded disjoint sequence converges to zero, then it follows from [4], Theorem 21.15, that every bounded set in  $E$  is relatively compact. This observation, together with the previous paragraph, Corollary 5.3 and Theorem 5.1, yields the following result.

**Corollary 5.4** *If  $E$  is a topologically complete, discrete, lc-solid Riesz space, then the following statements are equivalent.*

- (i)  $E$  is Dedekind  $\sigma$ -complete and every power bounded operator  $T \in Z(E)$  is uniformly mean ergodic.
- (ii) Every topologically bounded, disjoint sequence in  $E$  converges to zero.
- (iii) Bounded subsets of  $E$  are relatively compact.
- (iv)  $E$  is uniformly mean ergodic.

It should be observed that a lc-solid Riesz space  $E$  in which bounded sets are relatively compact, is necessarily discrete ([4], Corollary 21.13). Therefore, *Theorem 1.5 is an immediate consequence of Corollary 5.4.* The next example shows that the discreteness condition cannot be omitted in Corollary 5.4.

**Example 5.5** Fix  $1 < p \leq \infty$  and define

$$L^{p^-} = \bigcap_{1 \leq q < p} L^q(0, 1),$$

where the interval  $(0, 1)$  is equipped with Lebesgue measure  $\lambda$ . Fixing a sequence  $1 < p_1 < p_2 < \dots \uparrow p$ , the Fréchet lattice topology in  $L^{p^-}$  is generated by the sequence  $\{\|\cdot\|_{p_k}\}_{k=1}^{\infty}$  of Riesz norms. Moreover,  $L^{p^-}$  is reflexive. We claim that every bounded, disjoint sequence in  $L^{p^-}$  converges to zero. Indeed, let  $\{u_n\}_{n=1}^{\infty}$  be a disjoint sequence in  $L^{p^-}$  such that  $\sup_n \|u_n\|_{p_k} = C_k < \infty$  for all  $k$ . Defining  $A_n = \{t \in (0, 1) : |u_n(t)| > 0\}$ , it is clear that  $\{A_n\}_{n=1}^{\infty}$  consists of pairwise disjoint sets and so  $\lambda(A_n) \rightarrow 0$  as  $n \rightarrow \infty$ . Given  $k \in \mathbb{N}$ , it follows from Hölder's inequality that

$$\|u_n\|_{p_k} \leq \|u_n\|_{p_{k+1}} \lambda(A_n)^{\frac{1}{p_k} - \frac{1}{p_{k+1}}} \leq C_k \lambda(A_n)^{\frac{1}{p_k} - \frac{1}{p_{k+1}}}, \quad n \in \mathbb{N}.$$

Hence,  $\|u_n\|_{p_k} \rightarrow 0$  as  $n \rightarrow \infty$ , which proves the claim. Consequently, the Dedekind complete Fréchet lattice  $L^{p^-}$  satisfies all (equivalent) statements of Theorem 5.1 (and so, in particular, statements (i) and (ii) of Corollary 5.4). It should be observed that the centre  $Z(L^{p^-})$  may be identified with  $L^\infty(0, 1)$ , acting on  $L^{p^-}$  via multiplication. Evidently,  $L^{p^-}$  is not discrete and hence (as is well known; [11]), it is not a Montel space (that is,  $L^{p^-}$  does not satisfy condition (ii) of Corollary 5.4). According to [1], Proposition 2.11, the space  $L^{p^-}$  is not uniformly mean ergodic. We point out that  $L^{p^-}$  cannot contain any closed Riesz subspace which is lattice isomorphic to an infinite dimensional Banach lattice  $X$ . For, all norm bounded, disjoint sequences in  $X$  would converge to zero. As noted after Corollary 5.3,  $X$  would then be finite dimensional. On the other hand,  $L^{p^-}$  does have a closed subspace which is topologically isomorphic to the Banach lattice  $\ell^2$  ([1], Lemma 2.10).

It remains an interesting question whether every uniformly mean ergodic Fréchet lattice is actually discrete (and hence, Montel).

We end this paper with two observations concerning lc-solid Riesz spaces in which topologically bounded, disjoint sequences converge to zero.

**Remark 5.6** Recall that a locally solid Riesz space  $E$  is called (sequentially) monotone complete if every increasing Cauchy (sequence) net in  $E$  is convergent.

- (a) If  $E$  is a monotone complete lc-solid Riesz space and all topologically bounded, disjoint sequences in  $E$  converge to zero, then  $E$  is semireflexive. Indeed, it follows from [4], Theorem 21.8, that all bounded subsets of  $E$  are relatively weakly compact and hence,  $E$  is semireflexive.
- (b) If  $E$  is a sequentially monotone complete lc-solid Riesz space, then the following two statements are equivalent.
  - (i) Every topologically bounded, disjoint sequence in  $E$  converges to zero.
  - (ii) Every equicontinuous, disjoint sequence in  $E'_\beta$  converges to zero.

Indeed, this equivalence follows immediately from a result of Burkinshaw and Dodds ([4], Theorem 21.7, equivalence of (i) and (ii)). An inspection of the proof of [4], Theorem 21.7, shows that it actually suffices to assume that the space  $E$  is sequentially monotone complete.
